The Series System of Street Lighting Distribution

By W. P. HURLEY
Sales Engineer, Westinghouse Electric & Mfg. Co.

The series system of distribution has been used almost universally for street lighting since the first use of electric lamps.

Lamps, both arc and incandescent are very simple and more efficient when designed for series operation than are the multiple type. The maintenance of constant power at the lamp terminals where lamps are thinly scattered over a wide area is much easier with a series system of distribution than with any other system. The burning of all street lamps in the city for certain specified hours makes it desirable to turn the whole circuit on and off from a certain point so that such a system whether series or multiple cannot be used to distribute power for other purposes. As therefore, a special system is necessary for the street lamps, it has usually been made of the series type for the above reasons.

The special apparatus required to operate a series system from constant potential is very simple and inexpensive. The constant-current moving-coil transformer is the main factor in the maintenance of the necessary constant current. The film cut-out socket for the lamp enables the continuity of the circuit to be maintained when the incandescent lamp breaks or is removed. Both are very simple and reliable even with unskilled operators.

Any system of street lighting of sufficient merit to supersede the series system must depend primarily on the development of simple, reliable and inexpensive control apparatus for the individual lamps to enable them to be operated on the existing multiple distribution circuits.

A SERIES system of lighting distribution is one in which all the current in the circuit passes through each individual lamp in turn. The power as measured in watts taken by each individual lamp is determined by the resistance drop across that lamp, the current in all the lamps being the same. By properly regulating this current at the station, the wattage and illumination is maintained at a constant value, regardless of the pressure drop in the conducting wires of the system. Special short circuiting devices are employed to maintain the continuity of the circuit when the lamps burn out and to maintain a constant current in the circuit with the various conditions of load.

Such series systems are employed on a large scale to operate various types of lamps for street lighting. Conspicuous examples are the Mazda lamps in Chicago, the flame carbon arc lamps in Chicago and Indianapolis, the metallic flame or luminous arc lamps in Detroit, Pittsburgh and St. Louis as well as the old carbon arc lamps, both open and enclosed, which these lamps replaced. Where a suitable current and frequency are used the same circuit may operate both arc and incandescent lamps without difficulty.

As distinguished from the series system the multiple system of distribution requires lamps of the same voltage as the circuit rating, each of which has a resistance permitting the desired current to be taken. A simple switch at each lamp disconnects it individually from the circuit. As practically all factory and residence lighting is so operated approximately 95 per cent of the incandescent lamps used in this country are on multiple systems.

Other systems combine the principles of the series system with that of the multiple system by connecting a number of lamps in series and operating this series of lamps on a multiple circuit of higher voltage than is suitable for single lamps. Street cars thus use five of the substantial 110 volt lamps in series on their 550-volt circuits. However when one lamp breaks a filament, the other four will not operate as the circuit is then open. In some street lighting systems, notably at Milwaukee, series street lamps are connected in series and operated on constant potential in a similar manner. In such cases alternating current is employed

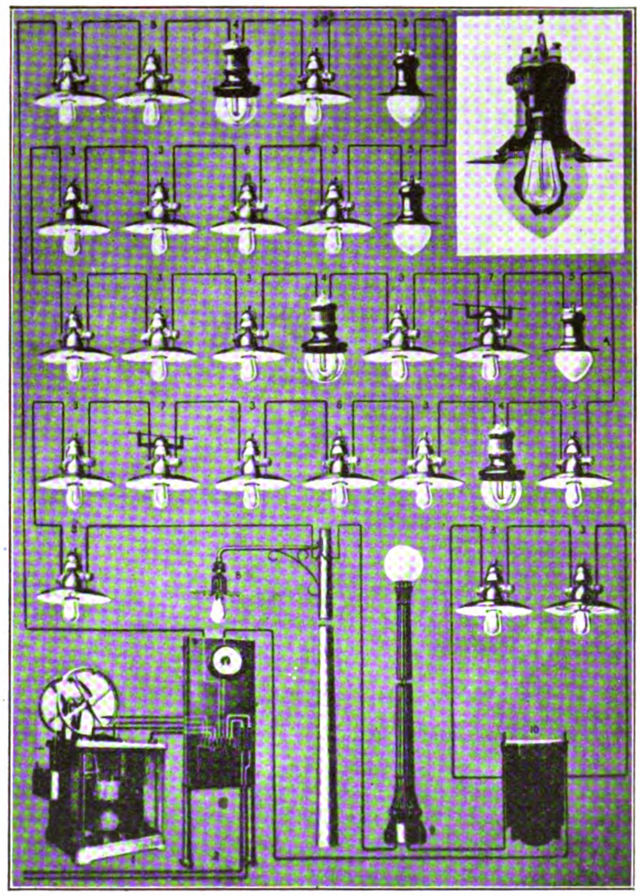

FIG. 1—STREET LIGHTING APPARATUS AS CONNECTED TO A CONSTANT CURRENT MOVING COIL REGULATOR

and special devices are provided to maintain the continuity of the circuit when individual lamps go out.

EXTENT OF USE

Approximately 1,000,000, street lamps in the United States are supplied by series distribution circuits. This constitutes practically the entire street

To be presented at the 357th meeting of the A. I. E. E., Chicago, Ill., January 9, 1919.

lighting distribution system of a large majority of the operating companies. Although requiring but a small proportion of the total kv-a. generating capacity, the system is of great importance to operating companies, because of the conspicuous position and essential duty of each small unit. It is especially notable that in its street lighting work, many operating companies render service to every one of the inhabitants whereas only 20 per cent or less, of the people may be making use of electricity in their homes. Yet, its total actual cost may be only 1 or 2 per cent of the total city budget and seldom over one dollar ($1.00) per year, per inhabitant.

Development

Although a great many other systems involving substitutes for the constant-current generator or moving-coil regulator have been tried out on a limited scale since the first introduction of the electric lamp some forty years ago, the series system is of as great relative importance as ever in street lighting, and is changed only slightly from the original concept brought out with the development of the first arc lamp by Mr. Charles F. Brush. This is an indication of the simplicity and fundamental soundness of the scheme.

The change from direct current to alternating current involved practically no change other than the lamps themselves, and the station equipment. The lines were seldom involved.

Advantage of a Series System

Street lamps constitute a comparatively small load in kv-a. which must be operated at various spacings over a wide area. The line cost per kv-a. of installation is relatively high. This is offset to a certain extent by a load factor of approximately 45 per cent where a 4000-hr. per year schedule is maintained. Furthermore, special precautions must be taken to maintain constant power at the lamps, regardless of the wide distribution. The series system is particularly adaptable to this service.

Consider that power is supplied to a 500-watt lamp every 500 feet along a street. A conductor smaller than No. 8 gage, is seldom used, as it would be too weak to be dependable, from a mechanical standpoint. From current-carrying consideration, a No. 14 wire would be ample although the watts lost in transmission, would be approximately four times as high as in a typical street lighting system.

If 110-volt multiple distribution is attempted, even with No. 8 conductor, not over two such lamps, the most distant being 1000 feet away, can be successfully operated, because of the poor regulation resulting from the voltage drop in the conductor. On a similar series circuit, 100 or more of such lamps, or a much larger number of smaller lamps, with as much as 40 miles of line wire, are readily operated.

Under such conditions there would not be over 50 kw. in load per square mile of territory served, and where the lamps are small, or spaced even further apart due to the presence of gas lamps in many locations or due to a scattered population, this load may be of the order of 5 kw. per square mile and 1 kw. per mile of single wire.

The low current in the series circuit prevents excessive drop in the line even with No. 8 conductor. The regulator compensates perfectly for this drop. The voltage of a single circuit is thus the sum of the voltages of the lamps on this circuit, and the line drop. It is evident that the long high-voltage circuits have the great advantage of less apparatus per kilowatt of load because fewer circuits will be required. Also a lower percentage of the line is used in simply running back to the station for purposes of control.

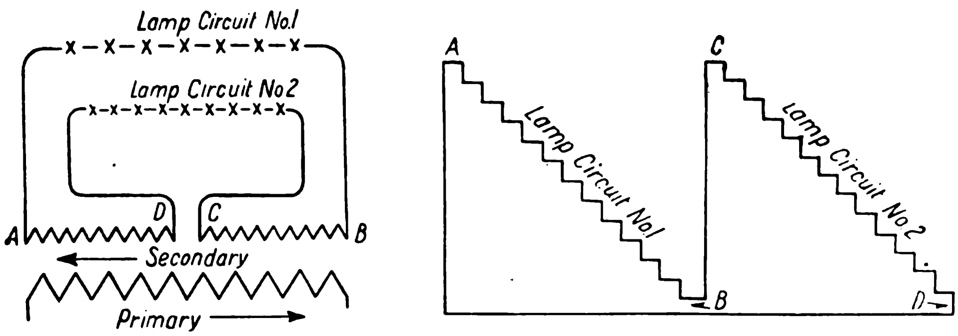

Fig. 2—Regulator with Two Interconnected Secondary Circuits and Development of the Diagram Showing the Voltage to Ground in the Various Parts of the Circuit.

The size of such a circuit may be limited by any one of several factors.

1. Voltage of the circuit to ground.
2. Number of lamps to operate on one circuit.
3. Insulation of lines and equipment.

Series lighting circuits on poles are subject to many grounds due to trees, lines breaking, crosses with other circuits and other causes. If an excessive voltage is supplied to any circuit an accidental ground at any point on the circuit causes a heavy strain on the insulation at other points because the drop across the large number of lamps is so great. This drop can be greatly reduced by cutting the circuit in parts and connecting a portion only of the generator or regulator winding between these sections. The whole combination con-

sisting of from two to four sections is thus connected in series as shown in Fig. 2 and takes the same current throughout the circuits. Such a system has been used in the d-c. arc generators for many years and also in the constant-current regulating transformers.

Grounds must be promptly removed from such a system. Where double grounds occur, one on each of two circuits, they may, if of low resistance, both be placed near enough the station (Fig. 2 at *B* and *C*) to practically short circuit one section of the regulator winding and the adjacent lamps, thus causing the current in that part of the circuit to increase to nearly 100 per cent of normal, while the remaining lamps would get practically no current. This double ground rarely occurs with good line construction, maintenance and methodical testing of the circuits. Equality of current in the two circuits may be insured by a relay so connected as to disconnect the regulator or circuits if current in the two circuits becomes unbalanced. In

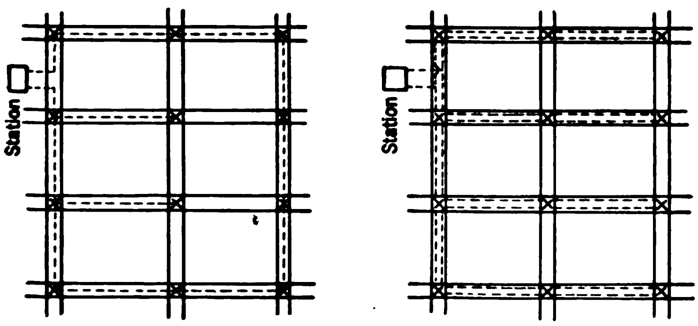

Fig. 3—Diagram of a Series Circuit on Streets Showing the Saving of Wire that May be Made by Using a Single Wire Circuit

general the merits of such a system of interconnection are so great that it is in very general use, particularly where the voltage of a circuit would otherwise exceed 5000.

In many cases one circuit is used for the all night lamps of a white way system and the others for the half night lamps. The high light load efficiency of the regulating transformer makes this arrangement very suitable.

The number of lamps on a circuit is influenced largely by the density of the lighting units and their size. In extreme cases 500 are found on a single circuit where there is a wide area of suburban territory to be lighted only by low candle power lamps. The numerous lamp loops of such circuits greatly increase the chances of open circuiting the whole system. To reduce the consequences of this the wiring should be arranged in loops so that cut-outs can be installed which automatically short circuit and disconnect a broken loop (Fig. 3 shows typical loops).

The cost of insulating lines and equipment rises rapidly with the higher voltages. This fact must be considered and balanced with the cost of additional circuits necessary to maintain low voltages. On overhead lines some systems successfully operate arc lamps up to 8000 volts. Underground circuits are seldom operated at more than 5000 volts as any breakdown in their insulation is much more serious from the standpoint of repair.

It is of great advantage to be able, in a series circuit, to operate the lamps on one street from one wire of the circuit alone without it being necessary to have the return circuit on the same street (Fig. 3). This may save as much as 50 per cent of the total wire required, and as many street lighting circuits are on pole lines already necessary for residence lighting such a use of a single wire system means the saving of a very considerable portion of the total expense. Little or no additional wiring in such single wire circuits is necessary to create loops by which large sections can be isolated either automatically as previously described or by means of a jumper. The automatic current regulation of the constant-current moving-coil transformer makes this perfectly feasible even though 90 per cent or more of the lamps be so cut out of circuit.

Line reactance with such small currents involved may usually be ignored as its only effect is to slightly reduce the load carrying capacity of the regulator. Variations of the lamps themselves from their rated voltage have a much greater effect on the total regulator capacity. For overhead lines this reactance drop at 60 cycles in single wire circuits is approximately 50 per cent and in return wire circuits, 25 per cent respectively of the resistance drop.[1]

Control

The operation of the street lighting lamps from dark until dawn or over some other fixed period makes a special condition of control not required for any other type of service. It is of great advantage from the standpoint of time and labor to be able to control all these lamps from a single point. Such has generally been the practice, thus making it impracticable to use the street lighting circuits and lines for any other service. Therefore, where a separate circuit is run for street lighting the series system has many advantages from the standpoint of installation costs and regulation over any other system.

Lamp Characteristics

In general it has been well worth while to make special lamps for series operation on account of the higher electrical efficiency or lumens per watt input.

In direct-current series arc lamps the wasteful sustaining resistance necessary to the multiple arc is omitted and the constant-current regulating device itself sustains the arc without material loss of power. In consequence of this difference, the direct-current arc lamp electrical efficiency is approximately 70 per cent

1. Formulas in Pender's handbook or in Bureau of Standards, Vol. 4, No. 2, page 317.

for the multiple and 95 per cent for the series lamp. Similar figures for an alternating-current system of enclosed carbon arc lamps so widely used at one time, were 90 per cent and 95 per cent respectively. The smaller apparent difference is, of course, due to the use of a reactance coil, instead of a resistance in the multiple arc lamp for sustaining effect.

The series system has been retained for use with Mazda lamps, as the efficiency of these lamps when made for a series system is much better than that of multiple lamps, being, in the case of the 100-c.p., 6.6-amperes series lamp, some 20 per cent higher than a 110-volt lamp of such a candle power.

Direct-current arc lamps were used on the early series circuits because of the greater steadiness and efficiency of the arc on direct current than on alternating

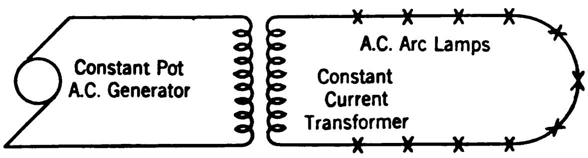

FIG. 4—CONNECTIONS OF A SERIES CIRCUIT TO A CONSTANT POTENTIAL SOURCE BY MEANS OF A CONSTANT-CURRENT TRANSFORMER

current. The alternating-current enclosed arc although much less efficient became very popular when alternating-current systems of generation and distribution became common because a series alternating-current circuit could be derived, from the usual 2300-volt constant-potential bus by a simple constant-current regulating transformer. This transformer had only a fraction of the first cost, maintainence cost or floor space of the motor generator or rectifier set necessary to operate a direct-current series circuit from the alternating-current constant potential bus. Yet the improvement, from the illumination standpoint, over all predecessors of the metallic flame, or luminous arc lamp introduced about 1907, was such that many of the direct-current series circuits necessary for their operation have since been installed.

Where incandescent lamps only are used there is obviously no need for direct current and it is well worth the slight expense to change the regulating equipment from direct to alternating current when direct-current series arc lamps are replaced by incandescent lamps. Such a change usually only involves the replacement of the station apparatus by a constant-current regulating transformer. An alternating-current circuit enables the use of the 20-ampere lamps from auto-transformers where high candle power lamps are desired. Safety coils can also be used on alternating current enabling the use of series lamps on fire alarm brackets, traffic posts and bridges in a way practically impossible on a high-voltage direct-current circuit with any degree of safety.

Frequency has had but slight effect in the development or use of series circuits. Apparatus has been available for all commercial frequencies except that arc lamps were never satisfactory on 25-cycle circuits.

APPARATUS

In the simplest and most commonly used series systems, a special constant direct-current generator or a moving-coil transformer for alternating current is required at the station to control the circuit and to maintain the correct current at the lamp.

In the old direct-current arc lighting machine, special designs utilized the reactance of the armature to prevent excess current in the lamp circuits, and used devices for shifting the brushes to obtain the necessary voltage up to the limits of the machine. Some of these regulators were extremely accurate and were sensitive enough to operate the high efficiency incandescent lamps now commonly used. The constant-current regulator commonly used for alternating current depends upon the electrical repulsion existing between the primary and secondary coils of a transformer under load to produce and maintain a constant current in the secondary or lamp circuit. Such a regulator is of great value because it can automatically maintain a fixed secondary current through any number of lamps from one up to its maximum capacity or with a wide fluctuation of the voltage on its supply circuit. When it is realized that an increase of 3 per cent in the current of the lamp circuit cuts the life of an incandescent lamp in half and

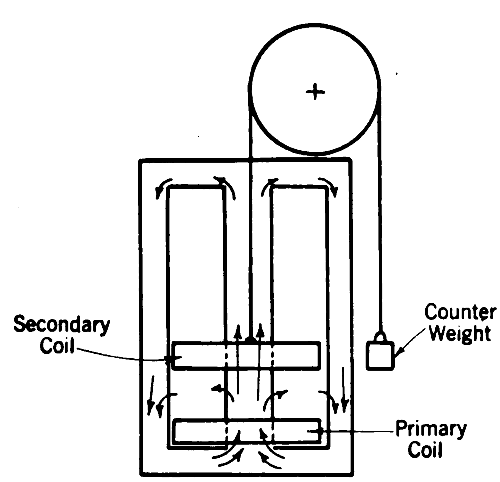

FIG. 5—FLUX RELATIONS IN A MOVING-COIL REGULATING TRANSFORMER SHOWING THE LEAKAGE OF FLUX BETWEEN THE STATIONARY AND THE COUNTERBALANCED MOVING-COIL

thus doubles the renewal cost, it can readily be appreciated that such a regulator is very cheap protection for the lamps as compared with any system that does not compensate automatically for all variations. To get a more definite idea of this relation it should be remembered that in extreme cases such as certain suburban districts using a great number of low candle power lamps the value of the lamps on the circuit is equal to that of the regulator controlling them. Under normal

conditions these lamps are renewed about three times per year. Accurate and reliable regulation is therefore necessary to keep these lamps up to rated candle power without getting at times a current sufficient to cause premature burnouts and increased expense in lamp renewals as well as in deductions for lamp outage. Renewals of four times per year would in this case require excess lamps equal the value of the regulator. The moving coil regulator is the only device which automatically compensates accurately for short circuits and double grounds on the series line or for voltage variation of the constant potential supply.

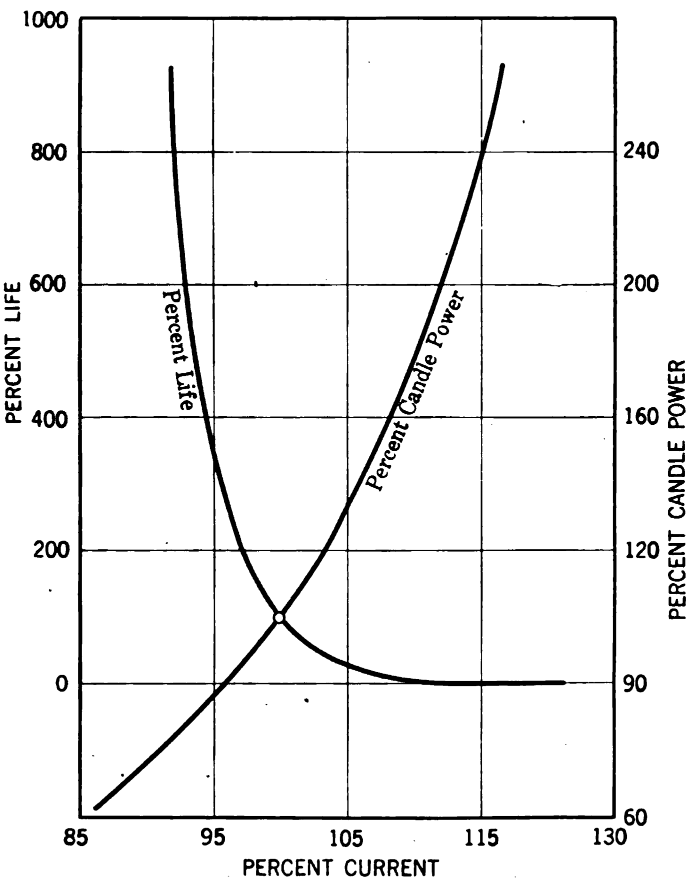

Fig. 6—Curves Showing the Change in Candle Power and in Lamp Life with a Change of Current in a Tungsten Filament

Such regulators are so substantial and reliable that small sizes have been successfully mounted on poles in transformer cases and operated by a time switch. Wherever possible however, they should be installed in a station so that the line can get more frequent and careful testing and an ammeter can be continuously kept in the lamp circuit.

In every series circuit the devices used on it must have a means of by-passing the current when the device itself is inoperative to prevent the opening of the whole circuit.

The arc lamp has a mechanism arranged as in Fig. 7 so that a shunt coil connected across the arc causes a switch to be closed and the arc short circuited when the drop across it becomes excessive. Another coil in series with the arc and line acts to give the correct spacing of the carbons or electrodes.

For the incandescent lamp a simple form of switch is incorporated in the socket. An insulating film is placed between the two sides of this switch. This film has

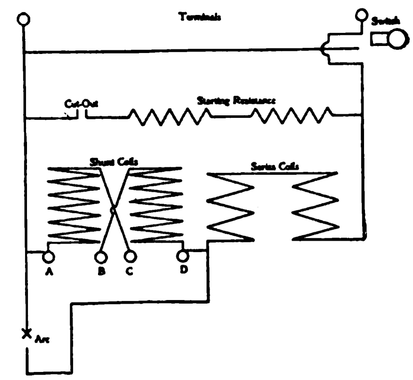

Fig. 7—Schematic Diagram of Circuits in a Series Arc Lamp Showing Three Parallel Circuits:

(1) Main circuit through the series coil and the arc.

(2) Shunt circuit to pull the carbons together when the voltage across the arc increases.

(3) Starting circuit consisting of resistance in series with a switch to cut it out when the arc burns.

The drop across the starting resistance through which the current first flows causes current to flow through the arc and series coil This coil pulls the carbons apart opening the starting circuit. The shunt coil prevents the arc voltage becoming excessive and can close the switch, if necessary, in the starting circuit thus maintaining a safe current path through the lamp.

normally only to withstand the drop across the lamp filament, *A* (Fig. 8) of 10 volts. However, if the lamp burns out the filament itself gives the effect of an infinite resistance, and the full generated voltage of the regulator or generator is impressed upon the insulating film, causing it to puncture and short circuit the lamp filament. In a moving coil regulator this

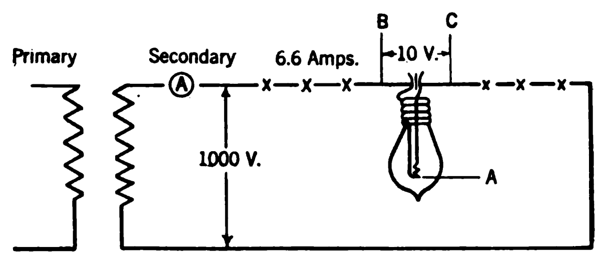

Fig. 8—The Film Cut Out Socket for Incandescent Lamps

When lamp filament *A* breaks, the voltage *BC* rises from that of the lamp to that of an open circuited regulator causing the film to break down and short circuit the lamp.

maximum voltage is approximately 25 per cent more than the full load voltage. A switch in the socket operated by the insertion of the lamp in this socket short-circuits this film when the lamp is removed.

Such film cutout sockets are very simple and inexpensive, and enable men with little training easily to renew the lamps, even under trying conditions of lamp location and bad weather.

In general, devices other than lamps have seldom been used to any great extent on street series circuits. On account of the dark until daylight schedule it is often

desirable to operate lamps indoors and around places where the high voltage possible on a series circuit cannot be tolerated. Underground circuits are often included in this status on account of the great expense of high-voltage cable. In such cases a special series transformer or safety coil is used. This safety coil can supply a small wattage at constant current and low voltage on the secondary circuit and yet be insulated for an extremely high voltage on the main series circuit.

Instruments or meters of a special nature are seldom required for series circuits. A high grade ammeter should be in series with the lamps for upon it depends the accuracy of the adjustment of the regulator and the life and candle power of all the lamps. The possible accuracy and permanence of the adjustment of the moving-coil regulator is well comparable to that of the ammeter, and little difficulty is experienced in its operation. Municipalities sometimes require a chart of the current in the series circuit and maintain curve drawing ammeters for this purpose. In other cities a jack on a pole allowing the insertion in the circuit of a plug with ammeter fulfills all requirements.

Maintenance

Maintenance and testing of series circuits is special only in that checks through the day are advisable in order to repair before dark any damage that may have occurred during the hours of non use. Troubles usually show in the form of grounds and open circuits. Simple electrical tests locate troubles, of this nature. They must be promptly removed to avoid damage to the lamps or interruption of service during the dark hours.

Summary

The advantage of the series systems of street lighting distribution consist of (1) effectiveness; (2) simplicity of control; and (3) high electrical efficiency of lines and lamps.

The disadvantages are (1) high cost of line per dollar of income; (2) high voltage; (3) special lamps.

The ideal system ultimately should be one to operate a highly efficient standard lamp from the existing multiple distribution lines necessary for residences and factories. Complicated special apparatus and special wiring, other than to the lamps is thereby eliminated. Reliable and inexpensive control devices must be available to turn the lamps on and off. Although much time and expense have been spent on such development ever since the lighting industry started, none has ever been sufficiently perfected to be worthy of generally replacing the simple series system.

TECHNICAL REPORTS ON INDUCTIVE INTERFERENCE

The Joint Committee on Inductive Interference, whose report to the Railroad Commission of the State of California was published in the A. I. E. E. Transactions for 1914, conducted a very exhaustive investigation of the phenomena of inductive interference between electric power and communication lines. In the course of its investigations the Committee compiled a number of technical reports on different phases of the subject, and owing to a wide demand, the Commission has published the most important of these reports in book form thus making them available for general distribution.

This volume, entitled "Inductive Interference" is bound in morocco leather and includes 1060 pages. It consists of the 30 most important technical reports of the Joint Committee selected from the seventy-one which were issued from time to time during the investigation. It also includes the preliminary and final reports of the Committee to the Commission, and the General Order No. 52 of the Commission prescribing rules and principles governing the construction and operation of power and communication lines for prevention and mitigation of inductive interference.

The book represents the results of extensive field and laboratory tests and investigations carried on for a period of over five years by a staff of electrical engineers from all parts of the United States, at an expense in excess of $100,000, and represents the thought and study of some of the most prominent power and communication engineers of the country.

There is no doubt that this volume covers the subject of inductive interference between electric power and communication circuits in a very broad and comprehensive manner and is, without question, the most complete and authentic work of its kind in existence. It will become an indispensable textbook for all students of the subject.

Subscriptions for this book have been received from interested engineers in most countries of the civilized world. A limited number of volumes have been printed in addition to the original subscriptions and are being distributed by the California Railroad Commission, San Francisco, at the low price of $10.00 per volume.

It is advisable for such engineers and others that want to secure this book to place their orders with the Commission as early as possible.

The United States Government has entered into contract with French Republic, under terms of which French Government is permitted to purchase $25,000,000 worth of machine tools from surplus stocks of such tools held by War Department in United States. French Government is to pay for such machine tools as it may purchase in ten-year 5% bonds of French Republic, payable in gold coin of United States.

Multiple Systems of Distribution for Street Lighting

BY WARD HARRISON

Engineering Department, National Lamp Works

The wider use of multiple lamps supplied from standard secondary distribution systems is considered as a step in simplifying operating problems and reducing the disproportionate cost which goes to cover fixed charges on special equipment and additional lines for street lighting only. The advantages in simplicity and flexibility of multiple connected lamps are discussed with particular reference to the frequent changes and extensions of street lighting service required in growing cities. The more general adoption of multiple street lighting is stated to be contingent upon fuller standardization of suitable methods of control applicable generally to existing electrical power distribution systems. Different devices in use or proposed for control of multiple street lamps are briefly described and the characteristics desirable in such apparatus are outlined. Attention is directed to the small differences in efficiency of present multiple and series incandescent lamps.

THE problem of securing street lighting most economically from multiple connections is one whose possibilities are far from exhausted, for multiple street lighting circuits and suitable control devices have not as yet progressed to the same degree of standardization as those of the series type. In the past, each individual case has been worked out, as far as possible, by adapting existing apparatus to meet the requirements of the particular situation. The purpose of the present paper is to review the systems now in use with their methods of control, and to indicate some of the more promising avenues of development.

FIG. 1—TYPICAL OVERHEAD SERIES ARC LAMP POST SHOWING INSULATING HANGER

EXTENT OF USE

In European cities, multiple street lighting systems are practically as common for both arc and incandescent lamps as are series systems in this country. Even here, where series circuits predominate, there are, notwithstanding, a large number of straight multiple systems in operation. It is true that they are largely confined to cities where low tension current only can be used. Of these cities, New York, with many thousands of such lamps, is the most prominent example. It is worthy of note, however, that in cities nominally lighted from series circuits, considerable numbers of street lamps will be found operated from the multiple distribution system.

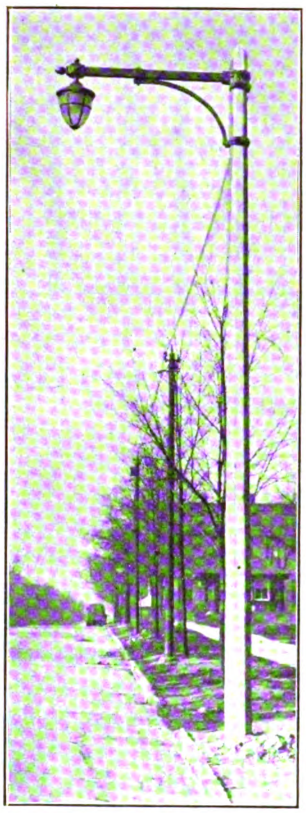

FIG. 2—SIMPLIFIED TYPE OF FIXTURE DESIGNED FOR MULTIPLE INCANDESCENT STREET LAMPS

ADVANTAGES

The following advantages which contributed to the standardization of multiple distribution for all other types of electric service apply also to street lighting.

1. Widest choice in number and sizes of lamps to be connected to circuit.

To be presented at the 357th meeting of the A. I. E. E., Chicago, Ill., January 9, 1919.

2. Ease of adding more lamps or lamps of higher wattage.
3. Simplicity and low cost of fixtures and accessories.
4. Safety.

The matter of flexibility is of immediate importance in the problem of designing street lighting for American cities and towns. There is not only steady growth in population and area covered, but there are also unexpected demands from time to time for increased street lighting service in given areas. The result, with series circuits of units of 50 to 100 lamps included on a single line, is that there must be an almost continual process of rearrangement and redivision of lamps among different circuits. In many cases service can only be provided after considerable delay and at relatively high cost, because existing circuits are so completely loaded that the addition of a few lamps makes necessary an extended revision of the system. No such limitations attend when the street lamps are operated from the general multiple distribution system.

An additional advantage of multiple street lighting is that, as mentioned above, the multiple circuit is now used exclusively by central stations for every other service. Were it used generally in street lighting as well, the reduction in types of apparatus required and the resulting simplicity of operation would benefit both the electrical manufacturer and the central station. At the present time, when a new real estate sub-division or allotment is opened, it is common practise for the lighting company to run a set of 2300-volt feeders to cover the plot, and to furnish service to houses as they are built. At the same time, a series transmission line is extended to furnish the necessary street lighting for the sub-division, and, in anticipation of increased requirements for service, both supply circuits are installed with a large excess capacity. The principal reasons for this duplication of service have been:

1. The arc lamp is inherently a constant current device and gives its best operation and greatest efficiency on series rather than on multiple circuits.
2. The series circuit is the simplest and most efficient method of supplying energy to comparatively small units scattered over wide areas; in many cases electric street lighting ante-dated the general use of electricity in residences by a considerable period.
3. A separate system of distribution has furnished a convenient means of automatically lighting and extinguishing street lamps from the central station.

There is an insistent demand for the extension of electric street lighting service in territory not now served by series lines, as for example, in Ohio cities, where in the past a considerable portion of the lighting has been furnished by natural gas, the supply of which is being rapidly depleted. In such territory the residences are, for the most part, furnished with current from overhead circuits along the rear lot lines, and the introduction of a pole along the street, to carry the series circuit has often met with a decided protest from the property holders. On the other hand, the cost of underground construction, with ducts running parallel to the curb, is almost prohibitive, especially in view of the increasing frequency with which concrete driveways now cross the parking in residence districts. High-tension underground lines passing through private property from the rear lot lines to the street, also involves expensive construction if safety is to be assured. Taken altogether, the conditions point toward the use of low tension multiple circuits from the pole lines in the rear to the posts on the street, brought out either overhead or underground, as occasion may require. Under these circumstances the underground construction may be in the form of a relatively inexpensive lightly-insulated sheathed conductor protected simply by fuses at the transformer. Such a conductor is very

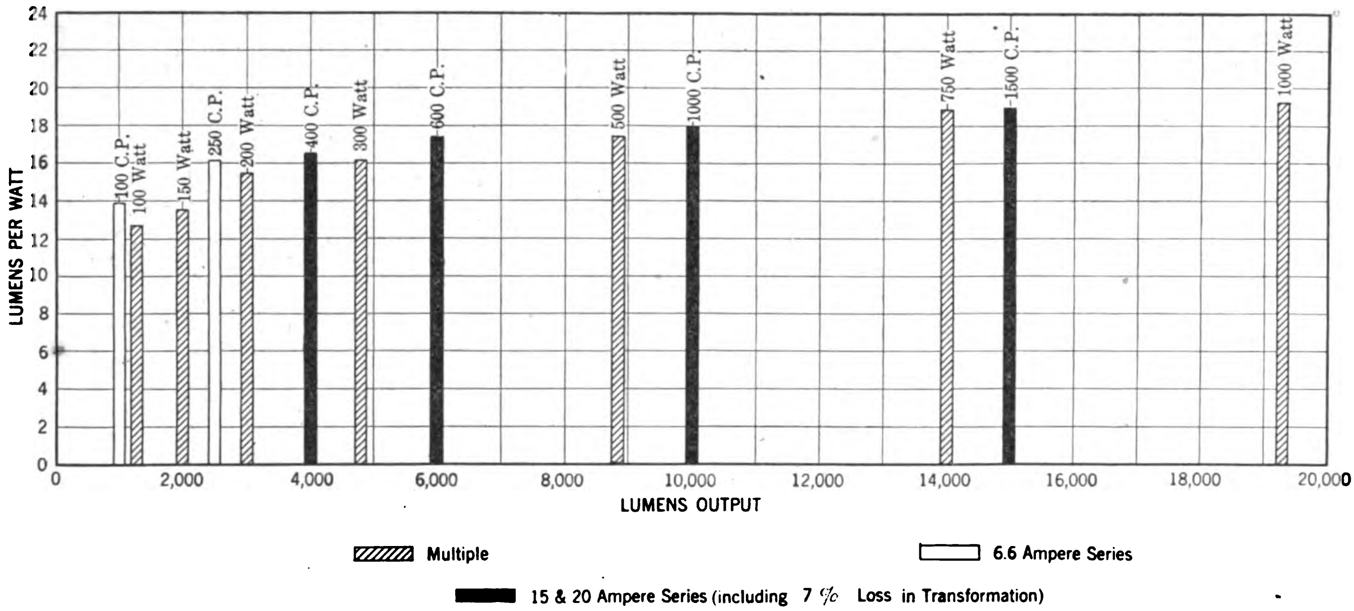

FIG. 3—COMPARATIVE EFFICIENCY OF SERIES AND MULTIPLE INCANDESCENT LAMPS

much less expensive than that designed for high tension work, and it can be installed without opening a wide trench across the lawn. If such a conductor is accidentally severed no serious harm can result, and the loss in itself is small.

Control

Today if incandescent street lamps were to be operated throughout the twenty-four hours instead of at night only, there would be no discussion as to the desirability of connecting them to the existing multiple distribution system, but the obvious difficulty in this practise lies in obtaining a thoroughly satisfactory method for turning the lamps on and off. Of course, wherever the load is sufficiently concentrated to justify a separate circuit from the substation, as in the case of many so-called White Way installations in the business streets of cities, the lamps may be switched at the substation in the same way as in the case of series circuits. Ususally, however, to bring the circuits back to the sub-station entails a prohibitive expense in copper and it is necessary to supply the lamps from several different transformers or feeders located nearer the lamps. For example, in the case of residence districts, it would be particularly desirable if the street lamps could be supplied from the same circuits located in each block, which now provide service for the residential consumers, as in Fig. 8.

The simplest plan is of course to have the lamps turned on and off by hand through the agency of a patrol messenger. Where labor is cheap, as in some of the European and Asiatic countries, this has been found a satisfactory and economical solution. In this country there are many cities where the White Way lighting is turned on and off by the policemen on duty. However, in view of the higher cost of labor in the United States and the extended distances between lamps, hand control is less desirable. Furthermore, the fact that gas companies are forced to rely upon manual control, and the difficulties which they have experienced, have served to deter electric lighting companies from resorting to it, excepting where there was no practical alternative in the way of a mechanical or electrical control.

Most of the efforts toward the development of remote control of multiple street lamps on 110-220-volt circuits can be grouped under three general types of systems,—cascading, relay switches operated from a pilot wire, and automatic clock or impulse-operated relay switches without separate control circuit. Diagrams illustrating these three methods of remote control are shown in Figs. 4, 5 and 6.

In the cascade method the section of lamps nearest the sub-station or control point are switched on and off by hand or a clock control switch. Energizing of this section serves to close a relay operating the switch for a second section. At the end of the second section is a similar relay which, being energized, closes the circuit for the third section of lamps, and so on. Opening the switch on the first section of lamps serves to de-energize the other sections of lamps in the same order. It is obvious that a method of this kind can be used for either alternating- or direct-current systems, or even a combination, and the load may be carried from as many separate transformers or sets of feeders as desired.

In the cascade system a failure of current supply in any section will turn out the lamps in succeeding sections of that cascade. However, this difficulty can be minimized by provision for hand operation of the switches in case of failure of one of the units.

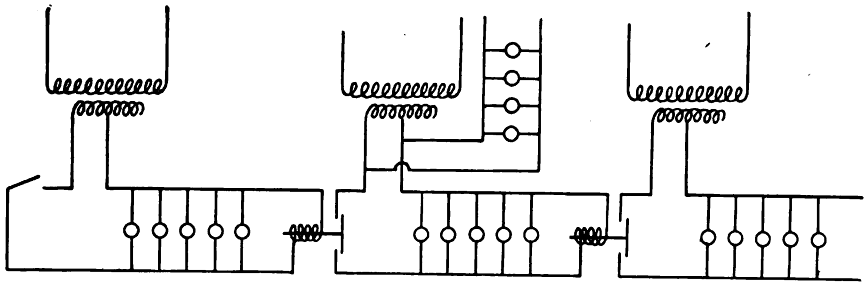

Fig. 4—Cascade Control of Multiple Street Lamps

The so-called pilot wire control utilizes a somewhat different principle for switching the lamps on and off. In this method, as will be seen from Fig. 5, lamps of the system are grouped in sections of suitable size to be controlled by a single switch and the separate switches are operated from a pilot wire which is energized from the sub-station or control point. The pilot wire can obviously be made of low current carrying capacity since it does not carry the lamp current but simply serves to energize the switch relays. Switch relays of several different models have been developed in connection with this pilot wire control. The simplest type consists of a solenoid-operated switch, which is closed or opened, depending on whether the current is on or off the control wire. Preferably, switches of this type should be closed when the pilot wire is de-energized, so that if the pilot circuit is accidentally opened the lamps will all be lighted, even though the break should occur during the daytime and therefore result in some waste of current.

Another type includes a mechanism with on and off positions. With this, the first time the control wire is

energized the lamps are lighted. The next time the lamps are turned off, and so on. Continuous application of current to the control wire is not necessary with this form, but there exists a possibility of lamps being left turned off when it was desired to have them on, or vice versa, due to the switches getting out of step. A pilot or signal switch at the control station has been suggested to obviate this uncertainty. Also, one manufacturer has provided for convenient hand setting of individual switches which might drop out of step.

In an endeavor to avoid the objections raised against the impulse-operated switches of the type just described other forms have been developed which operate from

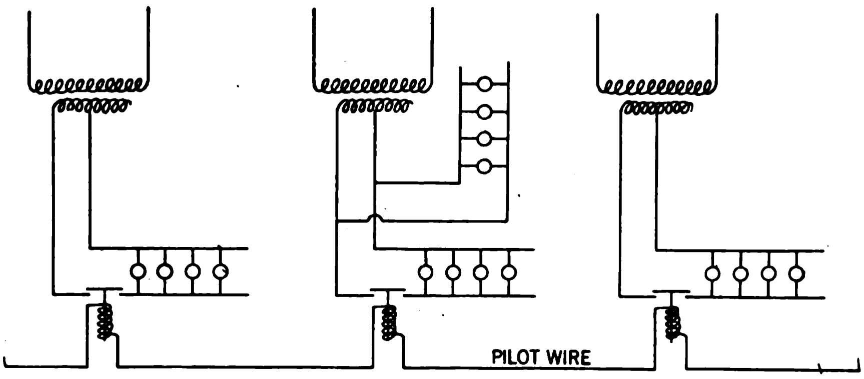

FIG. 5—PILOT WIRE RELAY SWITCH CONTROL

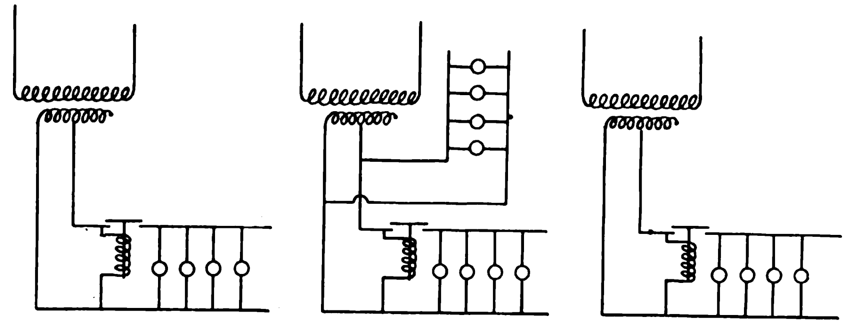

FIG. 6—CONTROL BY AUTOMATIC CLOCK OR IMPULSE OPERATED RELAY SWITCHES WITHOUT SEPARATE CONTROL CIRCUIT

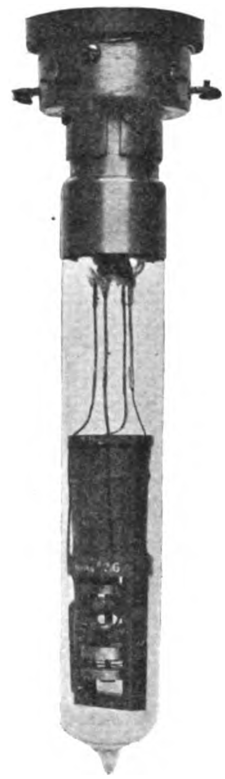

FIG. 7—SMALL RELAY SWITCH OPERATED IN INERT GAS

impulses of different strength. One of this type is illustrated in Fig. 7. The solenoid has two plungers so adjusted that a certain current will lift one and close the circuit. The impression of double this voltage on the control circuit lifts the second plunger which releases the catch and opens the lamp circuit. Such an arrangement using different impulses for the on and off position, has the advantage of avoiding the possibility of switches falling out of step. For instance, when turning on the lamps the control circuit can be given several impulses if desired without fear of leaving the switches in the wrong position.

In order to reduce the wattage required to operate the switch to the lowest possible value and to be able to carry a large number on a single control circuit, the parts are made light in weight. Corrosion and the resultant failure of switches is avoided by sealing the entire mechanism in a glass bulb filled with an inert gas. The capacity of these small switches is limited, but where a heavy current is to be handled they can be used as relays to operate a circuit breaker.

The pilot wires for operating the types of switches described may connect the switches in series. A greater flexibility in making extensions results if the switches can be operated in parallel, and in this case the neutral or grounded side of the distribution system may be used as one side of the control circuit and only one wire need be run to each switch. With a switch which operates on an impulse transmitted at low voltage, a relatively inexpensive galvanized iron wire such as is used in telegraph circuits, will frequently prove satisfactory.

Since the installation of a pilot or control circuit involves a certain amount of inconvenience and expense, considerable attention has already been directed toward the development of a remote-control switch system which would not require extra wiring beyond the necessary extension of the circuit from the feeders to the lamps. One of the earliest devices for accomplishing this result was the clock or time switch. Early designs were often unreliable in operation, and therefore quite unsatisfactory; however, there are available at present, time switches which withstand the severe conditions to which they are subjected. Again, time clock switches may be had which are electrically wound and which may be set to change the time of switching the lamps automatically, according to a

prearranged schedule of burning. Experience has indicated that clocks require a considerable amount of attention and regulation to keep them operating and in close agreement with each other. This factor, together with the question of initial cost, has hindered the more extended use of these devices.

A tiny synchronous motor-operated clock switch requiring an almost negligible wattage, is also available for remote control switching on alternating current circuits. This switch would find its best application in systems whose average frequency is well maintained and where there are but few interruptions of service. Otherwise the switches are liable to require a considerable amount of resetting.

Quite a different and a more satisfying solution of the problem of providing an economical and satisfactory remote control for multiple street lamps would appear to lie in the development of a system of switch controls operated without pilot wires and without clock mechanisms, but so arranged as to be actuated at will from the power station or control point.

One remote control switch now on the market is operated by "winking", or quickly opening and closing the supply circuit. Where the other load carried on the same distribution system is of such character that a momentary interruption of power does not interfere with its operation, this method will work out successfully.

Also, experimental apparatus has been built showing the practicability of operating switch relays by varying the frequency of the alternating-current supply a few cycles above and below normal. The opening and closing of the relay circuit may be controlled simply by the vibration of metal reeds similar to those in the familiar frequency meter, tuned to the proper frequencies. An arrangement of this kind would appear to be practical, at least in smaller communities where there are no serious difficulties attendant upon momentarily changing the speed of the generators.

Different experimenters have proposed also the use of relay switches receiving impulses from wireless waves, though so far as is known, the opportunities of development in this field have not been exploited.

Operation of the switch relays by means of selenium cells has been suggested. The operation of such switches would, however, be entirely dependent on the amount of daylight, and would not necessarily control the lamps according to the fixed hours of burning involved in many street lighting contracts. Furthermore, it would not be possible to turn the system on and off for test or other purposes, except by the additional provision of hand-operated switches.

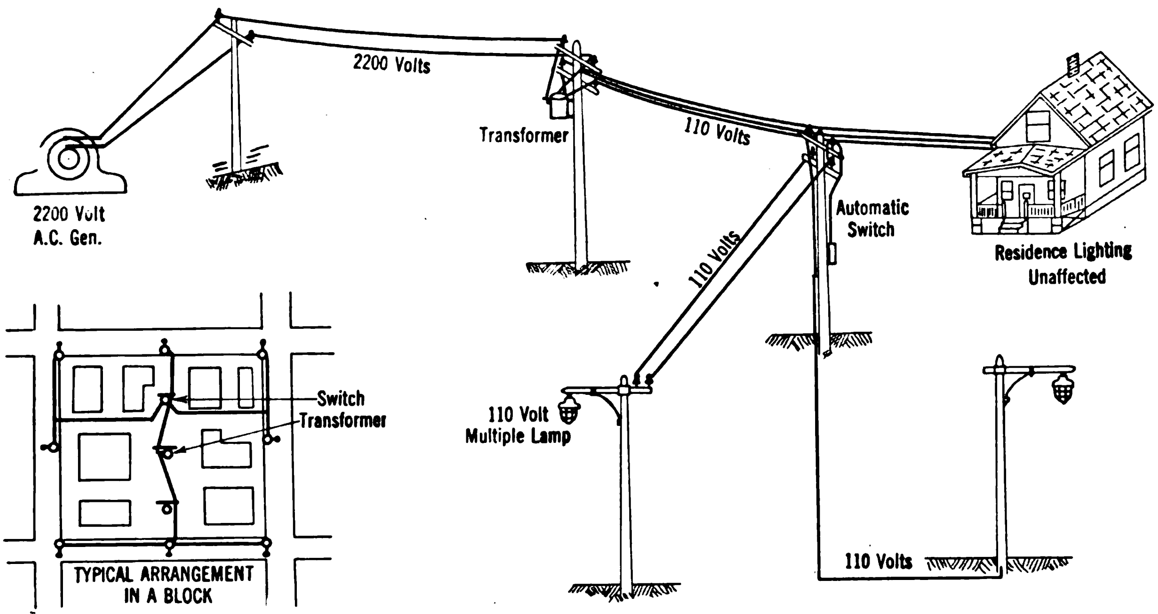

FIG. 8—PLAN OF OPERATING STREET LAMPS FROM SECONDARIES OF A HOUSE LIGHTING SYSTEM

The development of a phantom-circuit-operated control switch has been described elsewhere[1], and with further development this plan would appear to have promising possibilities. At present, however, the expense of the apparatus is too great to permit of an individual control for each lamp.

It seems reasonable to believe, however, that apparatus operated without a pilot wire should soon be developed by means of which street lamps can be lighted and extinguished at will, in a manner which is not open to any of the foregoing objections. At the same time it is evident that such a system, to be successful, must not involve a high cost per unit installed; also, it must not require the addition of any considerable amount of equipment on the 2200 lines; finally, its mode of operation, particularly if it involves the use of high frequency, must be such that there is no possibility of

1. *General Electric Review.*

injury to transformer insulation or to any apparatus forming a part of the present standard distribution system.

TABLE I.
COMPARATIVE EFFICIENCIES OF GAS-FILLED INCANDESCENT UNITS.

MULTIPLE LAMPS

Watts	Lumens	Lumens per watt
100	1,260	12.57
150	2,040	13.66
200	3,100	15.51
300	4,840	16.11
500	8,750	17.45
750	13,900	18.48
1,000	19,300	19.33

SERIES LAMPS

Amperes	Nominal candle power	Approx. watts	Approx. lumens.	Lumens per watt.
6.6	100	72	1,000	13.96
6.6	250	155	2,500	16.11
15.	400	240*	4,000	16.65*
20.	600	344*	6,000	17.45*
20.	1,000	556*	10,000	18.00*
20.	1,500	809*	15,000	18.55*

*Includes 7 per cent allowance for loss in transformation.

LAMP CHARACTERISTICS

The serious loss in light output when incandescent lamps are operated at less than rated voltage, is shown graphically in Fig. 9. Because of this characteristic it

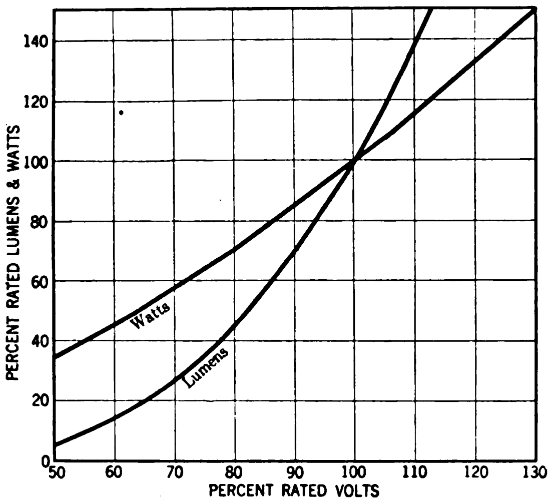

FIG. 9—VOLTAGE, CANDLE POWER AND WATTAGE CHARACTERISTICS OF MULTIPLE TUNGSTEN FILAMENT LAMPS

is essential with multiple systems that lamps be used whose ratings correspond closely to the voltage measured at the socket. In most cases with series systems, the operation of all lamps at proper efficiency is assured if the current is maintained at the correct value at the station. In some multiple installations a large number of lamps may be carried on comparatively long branches, so that there exists a considerable difference in voltage between sockets near the feeders and at the far end. This difference in voltage may become so great that the expedient of using lamps of two or even three different voltages is sometimes followed. Under these circumstances every lamp post must be marked with a symbol indicating the proper voltage of lamp to be used in the replacement of burnouts. In spite of this precaution, however, confusion of lamp voltages is very likely to arise unless the maintenance of the system is supervised with unusual care. A plan which is usually preferable is to provide for a very small drop between the street lamp and the supply circuit by running short branches and operating from one to three lamps on a branch. Table I shows the efficiency of the various sizes of multiple and series lamps computed in lumens per watt. For the 15-and 20-ampere units an allowance of 7 per cent has been made to cover loss in transformation. In Fig. 3 these data have been plotted graphically so that the comparative efficiency of series and multiple lamps of equivalent output may be readily seen. In the case of those series lamps which are available both in 6.6 and higher

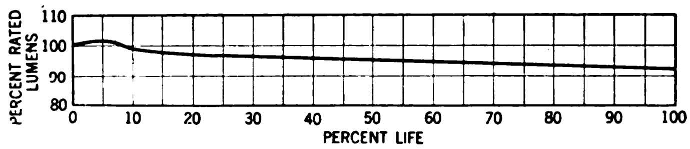

FIG. 10—TYPICAL LIFE-CANDLE POWER PERFORMANCE OF MULTIPLE TUNGSTEN FILAMENT LAMPS

amperages, the more efficient type has been shown. The very slight inferiority of multiple lamps from the standpoint of efficiency is worthy of note.

The depreciation in candle power or falling off in light output during life, is comparatively slight for the modern types of gas-filled incandescent lamps. The curve of Fig. 10, based on life tests of a large number of lamps of the sizes customary in street lighting, illustrates the performance which may be expected.

CONCLUSION

A fundamental reason for the increasing interest in multiple systems for street lighting is the growing realization that with present systems but a small part of the total cost of operation per lamp per year (usually not more than one-third) is to cover the actual cost of light; *i. e.*, cost for current and lamp renewals, or electrodes; the major portion consists of fixed charges on special equipment, floor space rental in substations, and proportionate charges for the use of pole lines and underground ducts. Furthermore, these latter charges are abnormally high per kv-a. owing to the small load carried on the average series circuit. Twenty-three hundred and 11,000-volt multiple circuits may be loaded at 400 to 4000 kv-a., while a 6.6-ampere circuit occupying an adjoining duct, is usually considered fully loaded at 20-30 kv-a.

Audible Electric Signals in Industrial Plants, and Acoustical Engineering

BY V. KARAPETOFF

Professor of Electrical Engineering, Cornell University.

The paper is a plea for a wider use of acoustic signals in industrial plants. It is shown that much time is wasted by the officials, experts, and important employees in trying to locate each other. With loud acoustic signals installed throughout a plant, in the shops, yards, and offices, it becomes possible to locate any of a considerable number of men instantly, using a simple code call for each. Such calls could be given only imperfectly by pushing a button, and for this reason a special code calling instrument has been developed, which closes electric contacts automatically, after having been set for a desired combination.

The actual conditions and the needs for acoustic signals are discussed in application to steel mills, shipyards, textile mills, printing establishments, coal mines, construction jobs, etc. It is shown that in addition to code calls, audible signals and particularly electric horns are used with advantage as extensions to telephone bells in noisy places, and also as warning signals for various purposes.

The general scope of the forthcoming art of acoustic engineering is then discussed, and its importance is shown in design of theaters, churches, and large auditoriums; also in the installation of fog signals. The problem of measurement of sound intensity is then taken up and the available means and devices are described. It is also shown that sound waves may be directly photographed under proper conditions and the laws of their propagation studied. Attention is called to the importance of experimental and theoretical study of the modes of vibrations of diaphragms used in acoustic devices.

I. The Need for Acoustic Signals

No industrial plant of any magnitude may be considered fully efficient unless means are provided for promptly locating any important employe, no matter where he may be within the plant. A private telephone system, however extensive, serves this purpose only as long as the needed man is at his desk, but as soon as he leaves his desk the problem of locating him becomes a hit-and-miss proposition. On the other hand a superintendent, a foreman, a millwright, a repair man, etc., is ordinarily useful only in so far as he can freely move about the shop without the fear that some one of importance may need him. Thus, within the last few years, under the tremendous impetus of the pressure for an enormous increase in the production of munitions of war, audible electric signals have been introduced into many industrial plants.

Such an electric signal is usually similar in its construction to the familiar electric "horn" used on automobiles. It consists of a diaphragm with an anvil at its center. A toothed wheel driven by a small electric motor strikes the anvil many times a second and causes it to vibrate vigorously. These vibrations produce the well-known warning tone, which carries over a considerable distance. The device is provided with a projector or horn the shape of which depends on whether it is desired to scatter the sound, to intensify it in horizontal direction, or to deflect it downward. Such motor driven signals are now made much more powerful than automobile horns, and are wound for 110 or 220 volts, direct or alternating current, so that they can be connected to a lighting or power circuit, and do not require a separate low-voltage battery.

With such electric audible signals scattered throughout the plant, it becomes an easy matter to locate instantly any person to whom a code number has been assigned. For example, when the manager wishes to speak to one of the assistant superintendents, who may be anywhere in the plant, he simply tells the telephone operator to sound this particular man's call. As soon as this assistant superintendent hears his call, he comes to the nearest telephone, and reports, whereupon the operator connects him with the manager.

It would be rather inconvenient for the telephone operator to sound various calls by hand; therefore a special code-calling automatic instrument has been developed for this purpose. The operator merely sets the desired person's code number on a dial and pulls a lever. A contact-making mechanism is thereby set in motion, which closes the electric circuit and operates the signals throughout the plant the required number of times (usually three times) and then stops automatically.

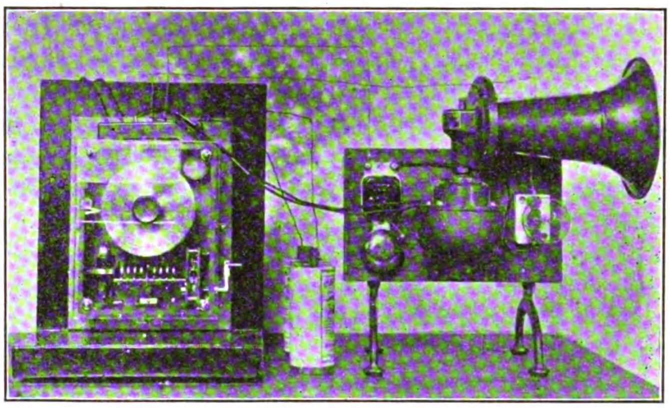

Fig. 1—A Code Calling Instrument (Klaxocator) and the Signals Which It Actuates, viz., an Electric Horn, a Bell, and an Electric Lamp

In noisy and in open places, or in large factory lofts, the electric horns mentioned above constitute the most

*Presented at the Rochester Section A.I.E.E., April 25, 1919, and the Erie Section, May 13, 1919.

suitable type of signal. In offices they may be replaced by less loud electric gongs, bells, buzzers, air whistles, or incandescent lamps. In some cases two separate circuits are run from the code calling mechanism, one circuit for ordinary calls, the other for fire-alarm gongs, or for some other special purpose. Sometimes two allied plants are operated side by side with a separate staff in each. Then the same code combinations can be assigned in both plants, but the horns in one or the other plant will sound according to which of the two circuits is closed.

A further application of loud electric horns in industrial plants is for extensions to telephone bells. The ordinary telephone ringer is not loud enough in many shops, when the foreman is away from his desk. In this case, a relay is connected in parallel with or in place of the telephone ringer, and when it is actuated, it closes a secondary circuit which causes an electric horn to sound. This call should be a single blow to distinguish it from code calls.

Audible electric systems are also used in various plants as warning signals on cranes and hoists, also to call a shifting locomotive, to indicate the beginning or the end of a certain operation, and for other local purposes. As in the case of any other convenience, once such an electric signal system has been installed, the superintendent, the foreman, and even the operatives themselves will find new uses for it.

II. Various Industrial Uses

1. *Steel Mills.* Of all types of industrial plants steel mills have buildings scattered over a particularly large area, with wide yards between. Taking into consideration also the noisy character of such mills, the importance of acoustic signals will become at once apparent. The three kinds of signals to be considered are:

a. Code calls for important employes.

b. Extensions to telephone bells in noisy places.

c. Warning signals on cranes, local signals at furnaces, rolls, etc.[1]

The large capital involved in the production of steel, the necessity for high-priced experts, and for a very rigid organization, all these factors make the installation of an efficient code calling system almost imperative; the trifling expense involved is entirely insignificant in comparison with the beneficial results achieved.

Now that such a code calling system is available, it is almost incredible that a large steel plant should continue in operation, without any provision whereby the important members of the staff could be instantly put into communication instead of playing hide and seek with each other. If one could compute the loss in production and the increased overhead charges, because of such delays, the figures would be unbelievable.

2. *Shipyards and Structural Iron-works.* Shipyards are not much different from steel mills in so far as the needs for acoustic signals are concerned, with the added problem of inconvenience of direct communication between two parts of a ship hull or between two ships under construction. Therefore it is essential to have a more elaborate code, telling each important man not only that he is needed, but also where he is to go, and whether or not it is an emergency call. This saves a great deal of climbing of stairs and ladders, and permits the overseeing force to utilize their time much more efficiently.

3. *Textile Mills.* Audible signals are essential in a textile mill on account of the great deafening noise of hundreds of high-speed machines and spindles used in many departments. Since telephones are practically impossible in such noisy shops, and since the code system is here needed only for a comparatively small number of superintendents and engineers, each person should be given two or three code numbers, in order that he may know where to go, what to do, and how urgently he is needed. In view of the large number of women and minors employed in the textile industry, fire-alarms should be particularly efficient, and the code calling instrument can be readily provided with a second circuit for sounding fire-alarm gongs, instead of horns. This provision may be in addition to the compulsory independent fire-alarm system, to insure more safety or to give supplementary information as to the location and extent of the fire. The huge Clark Thread Mills in Newark, N. J. are provided with electric horns for fire-alarm purposes, and the installation has operated satisfactorily for a number of years.

4. *Printing Establishments.* The character of work in a large printing establishment is such that the production manager, the man in charge of the machinery, and a few other experts have to cover several floors. The amount of work which they can accomplish depends essentially upon their ability to get in touch with each other, and upon the facility with which their superiors can locate them. A code calling system is therefore an essential adjunct in such a plant, and the signals employed vary from powerful electric horns in noisy press rooms down to gentle buzzers in the offices. A complete system of this kind has been in successful operation for some time in the large printing establishment of P. F. Collier & Son in New York City, which prints the well known weekly, and hundreds of thousands of copies of various books. One feature of this installation is that the code calling instrument is placed at the desk of a clerk, in the production manager's office, and the telephone operator has nothing to do with it. The local conditions are such that it seems desirable to limit the use of the system to important calls only, and to prevent clerks and office-

1. A number of electric horns are used on cranes, and for calling certain locomotives in the large steel mills of the Jones & Loughlin Co. in Pittsburgh.

boys from calling high-priced men on trifling occasions. The clerk in charge of the code-calling instrument ascertains the nature of the need, before setting the instrument in motion.

5. *Coal Mines.* A modern coal mine may have miles of passages and rooms underground, so that the superintendent, his assistants, the master mechanic, the electrician, etc. have to cover quite an extensive area. The superintendent of an old mine near Pittsburgh once stated to the writer that it might require half a day to locate him. In some states the law prescribes mine 'phones at the main workings, and this requirement makes a code calling equipment so much more important. The superintendent may be half a mile away from the nearest telephone, and could not possibly hear it or know whether he or someone else is wanted. A system of powerful horns installed throughout the mine and connected to a code calling instrument outside the mine would instantly convey the call and then the superintendent or whoever is called would come to the nearest telephone and report to the operator.

A further improvement of this system might consist in providing the superintendent, the foremen, the electrician, etc. with portable telephones, which could be connected to the line wires at any point. This is possible in many mines in which bare steel wires are used for the telephone circuit. In some mines, especially where rope haulage is used, the man on the train is given a piece of metal with which he short-circuits these two wires and causes a signal gong to ring at the winding engine. In this case the telephones are connected through condensers, and electrical connections are used similar to those which permit simultaneous telegraphy and telephony over the same wires. The same acoustic signals may be used for sounding emergency calls or for a general alarm, although the exact arrangement would have to be worked out separately to meet the conditions in each individual mine.

6. *Construction Jobs.* Audible signals could be made useful on large construction jobs, scattered over a considerable distance, for example, on large buildings, hydraulic dams, power plants, bridges, aqueducts, transmission lines and the like. Such audible signals may be used either in conjunction with temporary telephones, or without them. Where telephones are available, the audible signals merely serve to call the desired person to the nearest 'phone, no matter where he may be located. Without telephones, a more elaborate code may be needed, so that two persons could actually transmit simple information by blowing their horns. Where an electric power distribution is not available, horns could be operated from 6-volt storage batteries, or even from a few dry cells. Hand operated diaphragm horns are also available in which sound is produced by turning a crank by hand. A number of such hand-operated horns have been used in the trenches during the late war, especially for warnings of an approaching gas attack.

7. *Marine Applications.* The hazards of the sea today demand an equipment which will not alone fill the needs of routine service, but which will also prove unfailingly efficient under the stress of emergency. The intercommunication and signal equipment is the nerve system of the ship. During emergencies it becomes the one and only means which enables the officers to direct and coordinate the operations of the ship and its crew. Upon the signal equipment may depend the ship's safety. Voice tubes, gongs, whistles, etc. find their place, but for some purposes powerful electric horns are indispensible. A large number of such horns have been recently installed on various U. S. naval vessels. They can be used as a warning of hazards, as fire-alarm signals, for general alarms, as hoist signals, and also for code calls throughout the ship.

Another use which has not received sufficient attention is for communication between ships at a short distance from each other, or between a ship and the shore. Audible signals should have a distinct useful field for distances beyond the carrying power of the megaphone, and where wireless communication is not available. They can be operated at a much higher speed than an inconvenient and sluggish steam whistle, which moreover is supposed to be sounded for other purposes.

8. *Large Public Gatherings.* At large national conventions, festivals, and other public gatherings, there is often a need for promptly locating an official or a prominent guest in the crowd. This can be done in many cases by using audible signals, supplementing them where necessary by electric lamps, or other visual signals. For example, the chairman of an important committee or the secretary of the convention may be in any of the meeting rooms, in some committee room, in the lobby, or playing golf. Should the president or the chairman need him, his code call could be sounded throughout the grounds, and he could be located within a short time. Also any member of the convention who expects an important telegram or a long-distance call, may be given a code number and then he could move freely throughout the hotel with a confident assurance that he would know instantly when he is needed.

9. *Hold-up Alarms for Banks.* With a masked man pointing a revolver at him, about the only thing that the teller could do is to press a push-button with his foot. According to the local conditions, an audible signal connected to this push-button would cause an alarm to sound at the next street corner, where a policeman may be located, or in some large establishment nearby in which certain men have been trained and armed for such an emergency. Whatever the details this is a new application of audible signals well worth looking into. The problem is to prevent the hold-up men from getting away in the automobile, which usually waits for them outside.

III. Architectural Acoustics

The acoustic problem with which architects are concerned in large auditoriums, theaters, churches, etc. is that of proper audibility. A sound produced on the stage, be it a spoken or sung vowel, or the sound of a musical instrument, is propagated through the air, until the wave strikes the walls, the ceiling or any objects in the auditorium. Here the sound wave is partly reflected, partly absorbed by the material and a small part may even be transmitted outside. The reflected waves travel back and forth and are reflected several times before their energy has been completely spent and converted into heat. This nature of propagation of acoustic waves gives rise to several phenomena, mostly disturbing from the hearer's point of view. Thus the direct and the reflected wave may be out of phase with each other, and produce a weakening of the resultant sound (interference) at some points of the auditorium. At other points an undue strengthening (consonance) may take place. The reflected waves continue to be audible for some time after the source of sound has ceased, and they produce that annoying indistinct noise known as *reverberation,* which makes it difficult to follow a speaker. Again, *echoes* may be troublesome in some parts of the auditorium. A sharp short note instead of being heard once may be audible two or three times, spoiling the musical effect.

The foregoing problems and their effect upon the design of auditoriums and theaters have been treated quite thoroughly by the late Professor Wallace C. Sabine of Harvard University.[2] He made numerous tests on the relative absorbing power of different substances using organ pipes as the source of sound. The duration of the audible sound after the pipe has ceased was determined with a chronograph, and taken as a measure of reverberation. In one of the tests in a theater he obtained the following results:

empty, without seats...........	5.62 seconds
empty, with cushion seats.......	2.03 "
filled with audience............	1.14 "

He then introduced into the auditorium different absorbing materials, and by elaborate experiments and computations found the absolute values of their absorption coefficients, that is, percentages of the incident sound intensity that they neither reflect nor transmit.[3]

Using the correct values of coefficients of absorption, and knowing the velocity of sound in the air (about 1132 feet per sec. at 70 deg. fahr.) one can estimate the actual acoustic conditions at a given point in an auditorium, by a somewhat tedious process of construction similar to that of geometric optics. Prof. Sabine has also applied the well-known method of photographing sound waves to the determination of the acoustic conditions in an auditorium. He made small models of certain theaters, produced sound waves in them by means of an electric spark and photographed them by illuminating the wave fronts with another electric spark.[4] In this way it became possible to judge about the acoustic qualities of a projected auditorium with a considerable degree of accuracy, or to find the cause of faulty acoustics in a given hall.

Similar problems will probably arise in industrial plants and in other places in which acoustic signals will be gradually installed as a necessary adjunct for an efficient operation. In plants with complicated structures and machinery we shall find zones of silence or of reduced audibility; we may have to solve problems of reverberation and of echoes in places like a coal mine, and it will be necessary to determine the absorbing power of the principal materials and objects met with in an industrial plant. Fortunately, physicists and architects have done some splendid ground work in this direction, and acoustic engineers will mainly have to apply their methods to somewhat different structures and conditions.

IV. Measurement of Sound Intensity

If acoustics is to become a branch of applied science or engineering, the physical quantities involved, particularly the sound intensity, will have to be measured in some simple units and by means of a simple and robust instrument. A steam engine is guaranteed to develop so many horse power at a certain speed; an electric lamp is sold to give so many candle power in a certain direction. So in time an electric horn may be guaranteed to produce a sound intensity of so many "carusos" per square centimeter, at a distance of say one hundred meters from its diaphragm. At least the trend of the development in other branches of engineering has been from inaccurate and confusing notation by trade-names and by arbitrary numbers, to accurate specifications based upon physical units. Sound waves represent a certain mechanical energy, and therefore their intensity should be measured in energy units per square centimeter of area perpendicular to the direction of propagation. Of course, the question of selective sensitiveness of the human ear must also be considered, and the energy measured only within the audible range; the range of maximum sensitiveness of audibility lies between 700 and 3000 vibrations per second. Thus, when the candle-power of a search-light is specified or

2. See for example his article on Theater Acoustics, in the *American Architect,* Vol. 104 (1913), p. 257, and on Architectural Acoustics, in *The Building News,* Vol. 108 (1915), p. 180. Numerous references to other investigations will be found in these articles.

3. For other investigations on the transmission, reflection and absorption of sound by different materials, see F. R. Watson, *Physical Review,* Vol. 7 (1916), p. 125; H. D. Taylor, *Physical Review,* October, 1913; C. S. McGinnis, a thesis presented to the University of Pennsylvania, 1911.

4. For actual photographs see the references to his articles above. The method is described below under "propagation of sound."

measured, only the rays within the visual range are considered, and no credit is given the maker for ultra-violet or infra-red rays.

Just as with the progress of electric lighting of large spaces the need arose for simple portable photometers to measure the intensity and distribution of illumination, so in time we shall need simple practical devices for measuring sound intensity, produced by an acoustic signal, and its distribution in space. Such need has already been felt in connection with fog signals in which the volume of sound possible with one siren is limited as compared to the wide areas over which it must be heard under adverse conditions of wind.[5]

A simple indicator of sound intensity is the so-called Rayleigh disk which is a small and light vertical disk suspended freely on a fine quartz fiber and placed at an angle of about 45 deg. to the direction of the sound. When sound waves impinge upon it, it has a tendency to place itself at right angles to the direction of their propagation. The sound intensity of the waves may be computed from the observed angle of torsion.[6] In spite of this apparent simplicity this method has not been used much in practical acoustical measurements.

An instrument of considerable accuracy and sensitiveness for measuring sound intensity at a point is the *phonometer*,[7] developed by Dr. A. G. Webster of Clark University. It consists of a hollow cylindrical chamber (an adjustable Helmholtz resonator), one end of which is in communication with the atmosphere, and the other end is covered by a mica piston held in place by three stretched strings at 120 deg. to each other. The resonator is tuned to the pitch of the incoming sound, so that the impinging waves set the mica piston into vibration. The amplitude of vibrations is measured by means of a tiny mirror and a telescope on a scale. The vibrating system which consists of the three strings with a central block and the mica piston must also be tuned to the frequency of the incoming sound.

Some satisfactory measurements of sound intensity have been also made with a sensitive telephone receiver mounted on an intensifying resonator in front of it. Within certain limits the alternating current induced in the telephone receiver windings by the vibrations of its diaphragm, is proportional to the sound intensity, or at least a calibration curve may be obtained between known sound intensities and corresponding currents. The induced currents are exceedingly small and can be measured by the following two methods:

a. Using a crystal rectifier[8] and a d-c. galvanometer of high sensitiveness.

b. By means of a very sensitive vacuum thermo-couple.[9]

All these methods are reliable only with pure sounds of a single pitch, and the devices must be tuned to that pitch. Prof. Miller's *phonodeik*, which is a diaphragm device, responds to a considerable range of frequencies, and gives a photographic record of a complex sound wave. Unfortunately it distorts the relative magnitudes of the harmonics because of the resonant frequencies of the diaphragm itself; somewhat tedious corrections are necessary in order to reconstruct the actual sound wave.[10]

It will be seen from the foregoing, that the difficulties in measuring sound intensity are greater at the present time than those attending the measurement of the intensity of light from ordinary illuminants. It is to be hoped that the coming need for practical measurements of sound intensity will lead to a speedy development of a convenient measuring device, even though of moderate accuracy.

The fact that an industrial signal is intended for the human ear, and not for a measuring device, must not be lost sight of. An inanimate receiver tuned to a certain frequency may indicate a sound of great intensity which the human ear may not be able to distinguish from the din and howl of machinery. Systematic experiments will be needed on the sensitiveness of the human ear not only to sounds of different pitch, but to the same sounds accompanied by disturbing noises, simultaneous or in succession, continuous, interrupted, increasing or decreasing in intensity. Only a beginning has been made in this direction.[11]

V. Experimental Study of the Propagation of Sound Waves

A field of many possibilities in practical experimental acoustics has been opened, due to the development of a method for directly photographing sound waves. This method has been brought to a considerable degree of perfection by Prof. A. L. Foley of Indiana University.[12] In this method, use is made of the fact that a sound wave consists of consecutive condensations and rarefactions of the air, so that the density of the air in the wave front is different from that just ahead and just behind it. Therefore, if a moving sound wave be instantly illuminated with an electric spark, light will

be refracted at the places corresponding to the wave front, and an image could be obtained on a photographic plate. Foley used an electric spark as a source of sound, and another spark for illuminating the wave front of the sound produced by the first spark. The two sparks must be accurately timed, in order to catch the wave front in a desired position.[13] Dr. Foley has demonstrated in this manner a concentric wave from a point source, its reflection from a plane surface, and from a convex mirror; refraction of sound waves by acoustic lenses filled with different gases, the action of a diffraction grating, and some other fundamental phenomena in the propagation of sound waves.

These researches not only gave an experimental assurance to the purely theoretical statements of the fundamental laws of acoustics, but they also furnished a method for an experimental study of sound waves, under conditions which are too complex for theoretical computations. Dr. Sabine has applied this method to the solution of acoustic problems in some theaters. He made a small model of each theater, representing its cross-sections in a vertical and in a horizontal plane, and produced sound waves within each model at the stage by means of an electric spark. Photographs taken by means of another spark clearly show various trains of reflected waves, and the existence of conditions conducive to the formation of reverberations and echoes. By suitably changing the proportions, Prof. Sabine was able to improve the acoustic conditions on the model, and consequently was in a position to recommend with a fair degree of assurance, similar changes to be made in the actual theater.

It is quite possible that this method may prove to be of utility in the solution of similar acoustic problems in industrial plants. Photographs taken on models of complicated ship-yards, coal mines, or a mill full of machinery may explain some observed abnormal conditions such as zones of silence and a departure of the sound intensity from the simple law of inverse squares.[14]

VI. Diaphragms

A diaphragm is the most essential part of an electric horn; it is also an important organ in the telephone receiver and transmitter; it enters in the construction of the phonograph and other sound reproducing devices; it can be used for sound measurements, and it is also the sound receiving part of the human ear. For these reasons, numerous investigations, experimental and theoretical, have been made on all kinds of diaphragms and membranes.

As early as the eighteenth century, Chladni experimented with diaphragms of various shapes by putting a little sand on them and setting them into vibration by a violin bow. The sand is immediately driven away from the parts which are violently vibrating to places which are comparatively quiet. The resulting sand figures clearly indicate the shape of the segments into which the diaphragm is divided. The same diaphragm can be made to vibrate in a number of different modes by suitably holding it with the fingers, and bowing at different places. An account of Chladni figures may be found in almost any standard text-book on sound.[15]

A large number of investigators have worked experimentally on the study of vibrations of telephone diaphragms. In many of these researches a very small mirror was attached to the diaphragm, which mirror reflected light from a powerful source upon a scale on which the vibrations could be read directly.[16]

Some investigators have obtained direct photographic records of vibrations,[17] and a few attempts have been made to reflect light directly from a highly polished diaphragm. Observations have also been taken through a microscope of a stylus attached to the diaphragm.

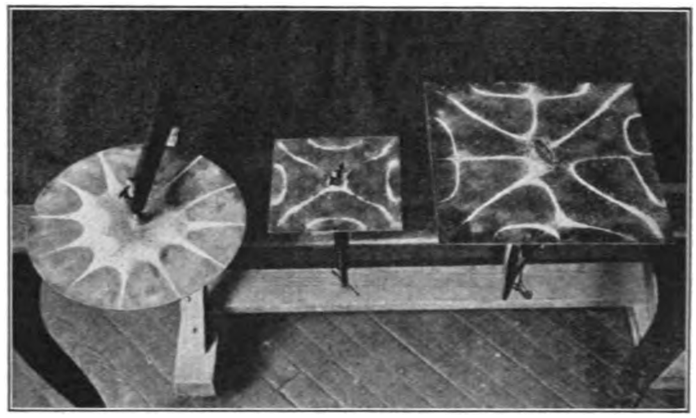

Fig. 2—Sand Figures Produced by Vibrations of Round and Square Plates, Showing Nodal Lines

Future improvements in signal horns and in telephone apparatus will largely depend upon our better knowledge of the modes of vibrations of diaphragms. In an acoustic signal we try to vibrate the diaphragm at one of its natural frequencies, so as to get as nearly as possible a pure tone, with a minimum of excitation. In a telephone receiver or transmitter, or in any other speech-reproducing device, the natural frequencies of the diaphragm constitute a disturbing factor, which gives it a selective sensitiveness for certain frequencies only.

13. A number of lantern slides were shown at the lecture giving results of Dr. Foley's experiments, and also some photographs of sound waves in auditoriums, taken by Prof. Sabine.

14. Dr. G. D. Shepardson, Telephone Apparatus (Appleton, 1917), p. 9; John Tyndall, Sound (Appleton, 1876) p. 287; A. Mallock, Proc. Roy. Soc., Part A. 91 (1914), p. 71.

15. A number of sand figures were demonstrated during the lecture using round and square plates.

16. For a fairly complete bibliography of these studies see E. A. Kennelly and H. Nukiyama, Proc. A. I. E. E., Vol. 38 (1919), p. 538.

17. A. Guyau, Le Téléphone, Instrument de Mésure (Gauthier Villars, 1914), p. 59.

The problem is further complicated by the fact that the diaphragm is seldom used alone, but usually has a horn (projector or mouthpiece) associated with it. This horn adds its natural frequencies due to the enclosed air and thus modifies the properties of the diaphragm itself. Besides, there are unavoidable little cavities where the diaphragm is built into a housing, and these cavities act as resonance chambers, adding to the troublesome selective sensitiveness of the combination.

A systematic study of these factors is still in its infancy, and offers a big and fruitful field for the future investigator.

The author wishes to express his appreciation to Klaxon Company, Industrial Division, and to its manager, Mr. E. Berg for their assistance in this investigation, and for the loan of apparatus, used at the presentation of the paper. He is also under obligation to the managers and electrical engineers of various industrial plants for the opportunity and facilities afforded in the study of their signal installations and acoustic conditions.

The Indispensibility to Each Other of Pure and Applied Science

BY H. A. BUMSTEAD
Professor of Physics, Yale University

I ACCEPTED, with considerable hesitation, the invitation to address you on the general subject of the relations of pure and applied science; and in particular of physics and engineering. Two years ago, Colonel Carty in his presidential address to the A. I. E. E. spoke upon this subject in a way which met with the hearty approval of all physicists. He has done more than most to foster cooperation between us and to bring about great practical results by utilizing the method of scientific research. What is there left for me to say?

One thing that I want to say is that Colonel Carty in his addresses has very generously acknowledged the debt which applied science owes to what is called pure science, and I wish to emphasize the reciprocal obligation. There is the obvious indebtedness for improved and convenient apparatus, material and machinery. How fast should we get on if we had, like Faraday, to insulate our own wire and make electromagnets out of links of anchor chain? The co-existence in cooperation between the two phases of science, which we call pure and applied, is of the very essence of the spirit and method of modern science, and is necessary to its existence.

When one speaks of modern science, one means, I think, essentially the method of planned and reasoned *experiment*, and, with a few sporadic exceptions, systematic experimentation was practically unknown until about 350 years ago. It marks a very great epoch in human history.

We are not far wrong in dating this great epoch from Galileo. Now Galileo begins his "dialogues," which have recently been published, by remarking that the workmen in the Venetian arsenal must have experienced many things that would be worthy the attention of philosophers. In fact, he takes as the foundation of his great and revolutionary theories, the experiences of the shop and the shipyard. And this attitude has been characteristic of the greatest men of science from that time to the present. In fact, since the time of Archimedes, there have not really been two streams of science, as we sometimes assume, but two aspects of the same thing, which I believe cannot be really separated. I think we may recognize in some sense the helplessness and sterility of either without the other, by considering two periods in the history of the past.

The Romans were probably the most narrowly practical people in the history of the world. They were great engineers, they covered Europe, Western Asia, and Northern Africa, with magnificent roads, and built bridges, acqueducts and great buildings, many of which are still in good repair, after nearly or quite two thousand years. They were wonderful adapters of known things to useful purposes; but, so far as I know, they never originated anything; never discovered anything. They were great lawmakers, but never discovered a single one of those more important "laws" which rule the physical processes of the universe. They went as far as they could go in technical matters without new discoveries. Then there was nothing to prevent the barbarians catching up with them in these things; and as they had not become degenerate through centuries of luxury and selfishness, Rome could not stand against them. I think we may see from the great experiment made by the Romans that a policy of narrow practicality, while temporarily successful, carries with it no promise for the future, and in time defeats its own ends in a great collapse.

On the other hand, it seems to me that the Middle Ages affords us a demonstration that there is such a thing as being too theoretical. Medieval scholasticism produced men of great intellectual ability. They had sound logical minds, daring imaginations, and many of them were most unselfishly devoted to the pursuit of truth. But they despised common things—gross matter, the vile and sinful human body, and in fact, the whole wicked and provisionally damned world. And they, too, reaped the reward of their narrowness. As in the case of the Roman engineers, they arrived at

Abstract of an address before a joint meeting of the A. I. E. E. and Am. Phys. Soc., Philadelphia, October 10, 1919.

some results of real value; but, out of contact with the external world, they soon ran out of material, and an intellectual revolution was necessary to free the human mind from the trammels of their system.

The same sort of thing would happen to physicists and engineers in a generation or two, if a wall could be built between us to shut out from each group the knowledge of what the other group was about. Fortunately, such a wall is impossible; and, short of an entire collapse of civilization and return to barbarism, one can see no reason why our fertile and beneficial cooperation shall ever again cease.

We must, of course recognize the limitations of possible cooperation; it does not mean coalescence. Colonel Carty pointed out in his address, to which I have referred, the difference in the motives which actuate the two groups in their researches, and the necessity for both motives. Each one of us has his own field to cultivate and must in general stick to it for the good of the whole. What we ought to do is to stick to our own jobs, but always be ready and anxious to help each other. There should always be some specially qualified "liaison officers" between us. Lord Kelvin is the archetype of the qualities needed for such service" and while we cannot hope to have a Kelvin in every generation, we have fortunately in this country a strong body of men whose interests and work lie in the borderland between pure and applied science. There have always been some university men of this type; and in the past decade or two, we have seen the development of industrial research laboratories whose personnel forms a natural and very effective bond of union and channel of communication.

As Col. Carty has pointed out, applied science has come to the happy state of being financially self-supporting, and more; while pure science from the nature of the case, never can be. Any aid which the industries can give to pure science, whether by endowments in universities and research institutions, or by supporting pure research in their own laboratories, will be most gratefully recognized by its devotees, and will no doubt bring great returns to the donors, though they may be sometimes long delayed and difficult to trace.

We, on the other hand, especially those of us in university work, have a reciprocal duty, to provide well-trained men for industrial research. In America this duty, up to the present, has been performed, I fear, very imperfectly. The defects have not, I believe, been so much in our graduate schools and doctor's theses as in the undergraduate colleges and schools of technology, to say nothing of our more elementary schools. Our whole educational system is too much permeated with softness,—we are too prone to put our trust in "get wise quick" schemes. Students are helped too much and taught too much, and unless they are of exceptionally good stuff, they get intellectually flabby, and are afraid to face the real difficulty alone.

Another short-coming of both colleges and technical schools in America is the scattering of the student's attention among many subjects of study. In academic colleges, under the elective system it often reaches the point of absurdity, but there is one redeeming feature: A student who knows his mind, or is well-advised, can get a good education by concentrating upon one or two subjects and attaining the beginnings of mastery—the only process by which we become educated either in school or, as happens to most of us, after we leave it.

Even in technical schools, I think we give too much time to many different small subjects under the misapprehension that a boy must be "taught" every separate thing that he will ever need to know. If we could give him a really thorough fundamental knowledge of fundamental subjects, not quickly and easily, and painlessly, but by good hard slugging, he would be in much better position to learn by himself the one thousand and one details that he will need to know in after life.

Whether or not this kind of education would be better for the practicing engineer, I have no doubt, that it would be much better for the man who is to engage in industrial research. And if a different training is needed for the two classes, then it is high time that undergraduate courses should be established along those lines, and that young men should be informed that a comparatively new profession is open to them which promises great rewards in usefulness, and reasonable ones in money to properly qualified men.

Dr. Jewett has pointed out in his admirable Toronto address, the one greatest need of industrial research is properly qualified men; there is plenty of money and plenty of apparatus, but an adequate supply of men is lacking: Not geniuses, but just competent, well-trained men. And the same shortage is very increasingly felt in pure science also.

We need, therefore, to secure public recognition for a comparatively new profession—that of scientific research, with two branches, one in the industrial field, and one in pure science. We must secure an adequate, but no extravagant financial return for those who practise this profession successfully; That is already partly accomplished in the industrial field, and all hope that it will not stop there. We must see that much better training is provided than has been the case in the past.

Finally we must advertise the new profession sufficiently so that young men of a suitable kind may be induced to enter upon this course of training.

In all these things the members of both of our societies can be of enormous assistance. It is a task well worth the doing; for its successful accomplishment will be of incalculable benefit to the world, both materially and intellectually.

The Technical Story of the Synchronous Converter

BY B. G. LAMME

Chief Engineer, Westinghouse Electric & Mfg. Co.

This is intended to be a semi-historical treatment of the engineering development of the synchronous converter as the author saw it. This development occurred over a long period of years and much of this was done inside of the electrical manufacturing companies, rather than in the operating field. In consequence, the many stages which eventually led to the great success of this type of electrical machine are but little known to the electrical public. The various steps in the development are described, covering many of the earlier troubles, and methods tried for overcoming them. The early evidences of hunting which eventually led up to the use of copper dampers; e. m. f. regulation; 60 cycle converters with their ups and downs and final success; the three-wire converter; the inverted converter; the application of commutating poles; the coming of the synchronous booster and the split pole types of converters,—all appear in the story, along with little incidents connected with the engineering and commercial side of the growth. Much of the material of the paper is given directly from the author's memory, checked at times by such technical data as were available. Representing principally the author's personal contact with the development, the story naturally cannot be considered as covering competitors' apparatus except in a very casual way. Errors of omission may thus be numerous, though unavoidable.

THE history of the development of the synchronous converter is comprised, almost entirely, within the inside records of a few of the large electrical manufacturing companies. The reason for this is partly that synchronous converters, since the first, have been built mostly in comparatively large capacities, and in connection with power and transmission systems which have been initiated only by a few of the larger companies.

From the operator's and the electrical "layman's" standpoint, the synchronous converter always has been a fairly well perfected piece of apparatus, without much history connected with it, except, possibly, from the 60-cycle standpoint. Just to look at it, it would appear to be a very simple piece of apparatus in that it is merely a direct current generator with polyphase collector rings attached at suitable points in the armature winding. In general, there was not much "field" development connected with it; that is, it appeared to be a fairly well developed piece of apparatus when it left the manufacturer's hands. However, the fact that many manufacturing companies, both in America and in Europe, made sporadic attempts to put converters on the market with more or less ill success, indicates that one had to "know how," in building converters, just as in other kinds of electrical apparatus. The fact is, that those companies which did succeed in making successful converters, attained success only through certain very expensive developments and much bitter experience, a considerable part of which is not known outside of the manufacturers themselves.

The writer feels competent to discuss this subject freely because he was one of the earliest in this field, and personally went through many of the principal troubles which developed in this line of endeavor. In fact, he believes that he was "over his head" in troubles with converters a considerable while before anyone else even knew that any serious difficulties existed. It is possible that if the manufacturers of converters in the early days had had any true conception of what difficulties would be encountered, they would have dropped the development altogether. Fortunately, they did not know what was coming until they were into the mire so deep that they had to fight their way through. However, as the manufacture of such apparatus has been largely in the hands of the two larger companies in this country, there was no very general public knowledge of the difficulties with which they were confronted. That there was recognition of the difficulties in the development of converters by manufacturing companies in general is indicated by the conditions the writer found in Europe about twenty years ago. At that time in America the 25-cycle synchronous converter was well established and the 60-cycle machine was making a brave attempt to obtain a foothold. He found that almost no manufacturers of electrical machinery in Europe, outside of those with close affiliations with the two larger American companies, were advocating or building synchronous converters to any extent. In answer to all requests for reasons why, he was told that they did not believe in them. However, later, the designers of several of the larger European companies told him that the problem of the development of 50-cycle converters presented such difficulties, that they hesitated to undertake the task, and they were even doubtful about undertaking 25-cycle converters. They admitted that they believed the American converters were quite successful, but that this was only accomplished through most difficult development and at high expense.

It may be mentioned at this point that these difficulties were not all inherent in the converter itself, but were due to a considerable extent, to the characteristics of the power systems to which it was connected. It has had to suffer on account of the sins of its near relations, so to speak. In its successful development, it had to incorporate within itself means for overcoming the difficulties due to the supply systems. Hunting, for instance, is initiated in the generating or transmission systems, as a rule, but the remedies, in general, have been applied to the converter itself. In other words, it not only has had to overlook such troubles in its associates, but, for best results, has had to reach back and partly suppress, or overcome them. Tak-

To be presented before the St. Louis Section, A. I. E. E., January 28, 1920.

ing all in all, it has been a "good-dispositioned" machine, so to speak, or it would have "quit flat" under some of the impositions against which it has labored.

Its coming was not glorified by any great publicity, nor by numerous complex technical or mathematical papers, but it simply grew up without attracting an undue amount of notice, and in fact, it was almost grown up, as far as the 25-cycle frequency was concerned, before the public had fully grasped its presence.

Coming now to the story of the synchronous converter itself, there is some question as to who actually suggested the earliest machine. The writer fully believed, in 1890–91, that he had devised a new and novel apparatus when he worked up the design specifications for an operative machine, but the records of the Patent Office said he was anticipated by Charles Bradley by some two or three years. However, the writer does not know whether Bradley ever built what might be called a commercial machine.

The early design of the writer was not unlike the modern synchronous converter, to the eye of the uninitiated, and it probably would have operated fairly satisfactorily under modern conditions of stable frequency, etc. However, this first machine was not built, due largely to the fact that it did not correspond to any commercial system of that time. In 1891 there were only two main frequencies in sight; namely, 133 cycles and 60 cycles; also there were no polyphase circuits available. Thus the synchronous converter at that time was the same kind of a waif as the polyphase induction motor, in that it had no polyphase system to which it could attach itself. Polyphase systems and lower frequencies were talked about, but, like the synchronous converter itself, were not yet in practical existence.

Sometime in 1891, the writer with several of his associates in the testing room of the Westinghouse Company, incidentally made a self-starting polyphase converter while doing some experimenting with a view to making a polyphase railway motor. It was desired to find what kind of starting conditions could be obtained on a railway motor with alternating current, instead of direct current. An experimental direct-current multipolar motor with slotted armature was equipped with a set of collector rings, in addition to its commutator, and was supplied with suitable polyphase current of low frequency. This machine was started and brought up to speed as an induction motor, in a series of tests, and, at synchronism, it delivered direct current from its commutator for self excitation, and to a lamp board, if the writers remember correctly. Anyhow, it was obvious from these tests that this machine could run synchronously and transform from alternating to direct current, which, however, was an expected result. This, therefore, constituted the first actual synchronous converter tested by the company with which the writer has been associated. While this test did not lead to anything in particular, yet it was convincing in showing that such conversion from alternating to direct current was practicable.

However, it was not until 1892 that deliberate efforts were made to transform, on a commercial scale, from alternating to direct current. It was becoming recognized that the polyphase system offered great future possibilities, and the synchronous converter began to be looked upon as one of the accessories of such a system. In consequence, arrangements were made to obtain tests on a relatively large scale to determine the possibilities of such a device. For this purpose, a standard 150-h.p., 500-volt, 850-revolution, four-pole belted type railway generator was equipped with four collector rings placed over one end of its commutator. Suitable brush holders were arranged for operating on these collector rings, in addition to the usual d-c. brush holder equipment. This machine was set up in the testing room and was started by means of a small direct current machine belted to it. It was synchronized with a low-frequency supply alternator, in the usual manner, by means of lamps.

From the first, this machine operated in a very satisfactory manner as a synchronous converter and a long series of tests were carried on by the writer, assisted Mr. N. W. Storer, at that time one of his associates in the testing room. It was determined that this machine would commutate in just as satisfactory a manner as when acting as a d-c. generator. As far as could be observed, the machine in every way was a practical one.

Meanwhile the whole synchronous converter situation was being worked over and it was decided that 3600 alternations (30 cycles) was about the best frequency for such machines. This was slightly higher than the frequency at which the tests were being made, but it was felt that this increase in frequency was permissible, in view of the excellent results already obtained at 3400 alternations (850 rev. per min., four poles). In those days everything was measured in alternations per minute, instead of cycles per second as in present practise.

About this time a Commission, which had taken up the development of the Niagara Falls power, had begun negotiations with the Westinghouse Company, with a view to getting certain electrical machinery constructed according to the designs of the Commission. The principal apparatus involved was an electric generator of 5000-h.p. capacity at 250 rev. per min. The design contemplated was the "umbrella type" with external rotating field and vertical shaft. This construction as a whole was considered practicable by the Westinghouse engineers, but the electrical proportions of these generators were not acceptable. The Commission had decided upon a frequency of 2000 alternations per minute (eight poles and 250 rev. per min., now $16\frac{2}{3}$ cycles per second). One of the objects in this low frequency was to be able to operate commutator-type motors by means of alternating current, as certain members of the Commission believed that this was the

solution of the small alternating current motor problem.

The Westinghouse Company objected to this low frequency and proposed, as an alternative, 16 poles at 250 revolutions, giving 4000 alternations per minute, or $33\frac{1}{3}$ cycles, this being the nearest that could be obtained to its own proposed standard of 30 cycles. There was very considerable discussion on the merits and demerits of these two frequencies. One of the advantages claimed for the higher frequency was that it would be much more suitable for synchronous converters, as the possible combinations of poles and speed would be very much greater than for $16\frac{2}{3}$ cycles. In fact, the lower frequency was considered to be more or less prohibitive as regards small or moderate capacity synchronous converters and induction motors, as their speeds would be too low. It is interesting to find how thoroughly this problem was appreciated, even at that early date, when only one experimental converter had been placed on test.

A compromise was finally made on the question of frequency by selecting a 12-pole machine for the Niagara generator, thus giving 3000 alternations, or 25 cycles. This was the origin of 25 cycles as a standard. The decision was made largely on the basis of future possibilities in the way of synchronous converters and induction motors.

The members of the Niagara Commission were informed that we had been carrying on extended tests with a direct current machine, modified into a converter and they witnessed the machine under load. During the discussion of the converter, the question came up as to whether such a machine had greater or less armature copper losses than a corresponding d-c. machine. Prof. Rowland, of the Commission, stated that he believed it to be the sum of the losses due to the alternating and direct currents in the windings, upon which Prof. Geo. Forbes, of the Commission, claimed that it represented the difference, these two eminent engineers taking opposite sides in all discussions. There was considerable argument, pro and con, with no prospects of a solution, as each of the contenders was depending purely upon argument. While such great authorities were discussing the matter, the writer thought it better not to venture an opinion, but he decided to make an actual test to settle the matter; so the following night he had the machine put on test as a converter to determine the comparative ratings, as a converter and as a d-c. generator. It so happened that in this machine there was a very definite load limit as a d-c. generator, for it had been proved by many tests that with a certain definite current for about four hours, it would begin to smoke. Consequently, tests were run to find the corresponding "smoking current" as a converter. The tests showed that with 400 amperes load, about the same heating (and smoking) conditions were produced in the armature copper as obtained with 280 amperes as a d-c. generator. This was a quite definite result, for it was known positively that this machine could not possibly carry 400 amperes for any appreciable length of time as a straight d-c. generator. Therefore, unquestionably, the armature loss was less as a converter than as a d-c. generator. When this result was placed before the electrical engineering members of the Commission, it apparently had no effect, as one of the members rejected the results and the other accepted them. However, the writer was thoroughly convinced, and so were all of his immediate associates. This, he believes, was the first actual test which indicated the relative capacities of the machine as a converter and as a d-c. generator.

To verify this test by calculation, both the writer and Mr. R. D. Mershon undertook to analyze the losses in the armature copper when acting as a converter. Mr. Mershon attempted a complete mathematical solution of the problem, whereas the writer undertook a simpler, less complete, but much quicker method by plotting out the calculated losses for each five electrical degrees of rotation of the armature windings. Curves were then plotted and the losses during a complete cycle of operation were summed up. This was worked out over-night so that the calculated results were available the next day. These showed 38 per cent loss as a two-phase machine and 57 per cent loss as a three-phase machine. This general result checked reasonably close to the actual test of the machine, considering that there were other losses involved in the problem. Mr. Mershon succeeded in his general mathematical analysis after about a week's effort and when he compared his results with those of the writer, they were found to coincide almost exactly. Thus the writer believes that he was the first to work out the problem of the relative losses, while Mr. Mershon was the first to make a complete mathematical analysis; and his mathematical results were published sometime later, but due to the newness of the subject, apparently little attention was paid it. Others published solutions much later, for which they received very considerable credit.

In addition to the above, some interesting experiments were carried on with this first experimental converter, especially in regard to methods of starting. Among other tests, the writer brought this machine up to speed as an a-c. single phase motor. By using the d-c. series winding as an a-c. field winding, connected in series with the armature to form an a-c. series motor, he actually started the machine from rest, brought it up to speed and then threw over to synchronism. This forms, therefore, a very early test of a large capacity series-wound single-phase commutator type motor.

These early synchronous converter tests were so successful and made the problem look so simple that apparently there was going to be no difficulty in developing a commercial line of converters, provided suitable low-frequency polyphase circuits were available. However, the real difficulties in synchronous converter operation did not develop until a considerable time later.

Based upon the aforesaid successful results, the West-

inghouse Company prepared a relatively large synchronous converter exhibit for the Chicago World's Fair in 1893. Some description should be made of this exhibit, as it was the first public exhibition of this type of apparatus, as far as the writer knows, where such machines were shown in actual operation.

In the latter part of 1892 the Westinghouse Company authorized the preparation of a polyphase exhibit for the Electricity Building at the World's Fair. This exhibit comprised a 250-h.p., two-phase, 60-cycle induction motor belted to a 500-h.p., two-phase, 30-cycle a-c-d-c. generator. From the d-c. side of this generator 500-volt direct current was to be furnished for operating any 500-volt direct-current apparatus in the exhibit, while from the a-c. side of the generator, a 30-cycle, two-phase current was to be supplied to two synchronous converters, one of 500 h.p. and the other of 60 h.p.

In view of the fact that no polyphase induction motor of such large horse power had ever been shown before and that the a-c-d-c. generator and the synchronous converters were both novel, this exhibit, taken as a whole, was a great novelty.

In looking over the original design specifications for the a-c-d-c. generator and the synchronous converter, dated Dec. 12, 1892, the writer finds some very interesting matter, from a historical standpoint. The specification for the 500-h.p. converter calls for a six-pole, 600-revolutions (30-cycle) 525-volt machine very much along modern lines of design. The pole pieces were laminated, but cast into the yoke, instead of bolted in. The armature was of the slotted type and with a "parallel type" winding, as in modern practise. This early specification calls for a brush lifting device for the d-c. brushes, although as actually built, the machine did not use such a device. However, it indicates that the possibility of brush trouble with a-c. starting was recognized. This converter was arranged to be started from low-voltage taps on an auto-transformer, and it was intended that the machine should come up to synchronous speed on the lowest tap and then be transferred to full voltage by successive steps. This was actually carried out and the converter was started and synchronized in this manner. The original specification also called for series field coils, for compounding but these were not incorporated in the actual machine. A further feature was that this converter was provided with a relatively small airgap and very light shunt field coils, compared with d-c. machines of corresponding dimensions, as built at that time. Thus this converter, *as specified*, was more nearly of the modern type than the designs which followed it during the next four or five years. Another interesting feature was that the field coils in starting were switched from series to three parallels and closed through a starting resistance, thus anticipating practise of several years later.

The small converter, of 60 h.p. had cast iron poles and yoke and operated at 900 rev. per min. This was also arranged to be started by auto-transformers and with high resistance in the field.

The a-c.-d-c. generator was similar to the above described synchronous converter, except that it had a large airgap with relatively heavy field coils and was separately excited from a 120-volt exciter, of which the field excitation was varied to control the main generator.

This exhibit was delayed considerably and was not ready for operation until about the first of July, 1893, although most of the apparatus was installed in May to serve for a stationary exhibit. On account of this delay, quite a number of other exhibitors thought that this exhibit, from the operating standpoint, was all a "bluff." However, operation was delayed until the writer visited the exhibit about the first of July. He then reviewed the entire layout of this exhibit and assisted in testing out some of the individual parts. Then one Sunday afternoon when there were no visitors around, but only exhibitors and attendants fixing up their exhibits, the 250-h.p. induction motor was started up, bringing the a-c.-d-c. generator up to speed. The large synchronous converter was then thrown on and brought up to speed, also the small converter and various special apparatus, which was to be operated by current from these two converters, was set in motion, so that the entire stationary exhibit became very much alive in a few minutes time. It was interesting to see the various attendants and exhibitors in the neighboring spaces stretching their necks to see what was going on. With everything in operation, it made considerable noise, especially noticeable with everything else in the building at a standstill. People flocked from all directions to see what was happening. An engineer from a neighboring German exhibit came over and shook hands with the writer and admitted that he was mistaken about the Westinghouse company, as he had thought that the whole exhibit was never intended to be run.

When this exhibit was first operated, several unusual things occurred which were not anticipated. One of these was a peculiar "beating" sound which occurred at times in the 60-h.p., 50-volt converter. Under certain conditions of voltage and field strength, it made this peculiar noise and sparked to a certain extent, even when carrying no load. However, under normal operating conditions, there was no such apparent trouble and no further investigations were made. This was probably the first observed case of "hunting" in a synchronous converter, but it was not serious enough to lead anyone to suspect an inherent difficulty. Another thing that developed in starting this exhibit was the relatively large input required to start the synchronous converter and bring it up to synchronism. Apparently this had considerable to do with the later practise of using starting motors to bring the converters up to speed. Starting the 500 h. p. converter from rest and bringing it up to synchronism proved to be about all that the 500-h.p., a-c.-d-c. generator could handle

and the effects on the other service operated from the a-c. side of the generator were rather appalling when the large converter was started.

All of the above refers to Westinghouse apparatus at the Chicago Exposition. The General Electric Co. had one relatively small capacity synchronous converter on exhibition, which the writer examined. This appeared to be a very nicely constructed machine, but as there was no suitable supply circuit the machine was therefore not operated. For this reason apparently, it attracted but little attention, as the electrical public at that time had heard practically nothing about synchronous converters.

25-Cycle Converters

As far as the writer's knowledge goes, the next step in the synchronous converter development was in connection with a couple of 200-kw., 25-cycle converters to be used as exciters for the Niagara Falls Power Company's 25-cycle generating plant. These machines were built in 1894 and were very much along the lines of the World's Fair 500-h.p. converter, having laminated poles, and with no dampers, the need for the latter not having developed. One of these machines was operated from one of the Niagara generators in the Westinghouse shops and apparently ran all right except on one occasion when there was a violent "pumping" or "beating" sound in the converter and it sparked very badly, so much so that it was cut off the circuit. When put on again, it ran satisfactorily and it was assumed that some mistake had been made which caused the preceding trouble. This was not recognized as a case of hunting, neither was any connection noted between this trouble and the few instances of hunting in the small machine at the World's Fair exhibit. In fact, here were two cases of hunting on record which, however, did not attract any particular attention. It was only after the converters were installed at Niagara Falls that the true seriousness of the difficulty developed. It was then found that these machines would not work at all as synchronous converters, due to apparent irregular rotation accompanied by the violent sparking, etc., noted in one of the shop tests.

Meanwhile the General Electric Co. had been following up the synchronous converter situation and was building such machines for some of the Edison companies to be operated on 25-cycle engine-type generators. A number of these machines were installed and appeared to work in a quite satisfactory manner. In parallel with such development, the Westinghouse company was also building 25-cycle converters under contract with a number of customers, apparently unaware that they were facing a very difficult situation. Outside of the two converters built for exciters, as mentioned above, the first serious trouble encountered was in connection with a couple of chemical plants at Niagara Falls. Several converters had been contracted for by two such plants and also the World's Fair 500-h.p. converter, already described, had been reconstructed into a 500-kw., 550-volt machine, which was set up in the main power house at Niagara Falls. This latter machine appeared to operate in a quite satisfactory manner, and we thus gained undue confidence. The General Electric Co. had quite a large contract for synchronous converters for the Pittsburgh Aluminum Company's Plant at Niagara Falls. Apparently it approached this matter with full confidence also.

The Westinghouse converters in the chemical plants at Niagara Falls were built along well known lines, having slotted armature, laminated poles, etc. The General Electric machines for the Aluminum company were somewhat more radical in type, having surface wound armatures and metal brushes on the commutators. The machines of both manufacturers soon got into serious trouble, although from quite different causes. The Westinghouse machines were troubled almost at once with hunting, as we now call it. In both plants, known as the Niagara Electric Chemical Co. and the Chemical Construction Co., the converters refused to operate without very bad hunting at times. It was then appreciated that the trouble indications in the shop tests, and in the Chicago exhibit, really meant something. The writer and Mr. C. F. Scott spent a long period working on these converters to stop the hunting, and all kinds of "stunts" were tried, one of which was short circuiting part of the field coils. It had been noted that the exciting current varied as the machine hunted and therefore it was assumed that a heavy short circuited path around the field poles might exert a steadying effect. This idea proved to be correct, but this damping was not sufficient to stop the hunting. However, in the course of these tests, the entire field circuit was disconnected from the commutator and closed on itself, on one of the machines, and it continued in synchronism and carried load as a converter through armature excitation alone, and what is more, there was absolutely no hunting under this condition. This was tried on the machines in both the chemical plants and was effective in both cases. An objection, however, was that the power factor of the a-c. input was quite bad, due to the large magnetizing current. Various tests were made to determine what was going on during this hunting and it developed that the armature of the converter was acting alternately as a generator and as a motor, and the armature magnetomotive force was reversing with each "beat." It appeared also, that the machine was alternately gaining and losing speed in respect to the supply system, during the beats. In other words, the armature was running at an oscillating speed.

While these tests showed pretty clearly what was happening, the proper remedy did not suggest itself until sometime afterwards. One thing was evident; namely, none of the converters would "hunt" when running without field excitation. Therefore, it at once suggested itself that if the airgaps were made very

small, that is, comparable with those of induction motors, then the converters might be made to operate without hunting and with magnetizing currents and power factors comparable with good induction motors. As this was the only feasible solution in sight, plans were immediately made to furnish new magnetic fields for one of the Electro-Chemical company's machines, in which an extremely small airgap would be used. This was done as quickly as possible and on trial this machine appeared to give quite satisfactory operation. Further tests indicated that the hunting problem in general was so serious that we might be obliged to go to this "induction converter" eventually for all synchronous converter work.

However, while this was being done, a further analysis was being made of the general problem. The writer, with one of his associates, undertook to explore the magnetic field conditions in one of the Niagara converters during hunting to see what was actually occurring. A wooden arm was fixed over the commutator with a large number of uniformly spaced holes in it, through which metal contacts were pushed to the commutator surface. Voltmeter readings were taken for each position, over a wide arc of the commutator. It was found that the voltage readings were varying, with the beats in the machine, from a high value in one beat to a low value in the next. Plotting out these two extremes, two curves were obtained, as indicated in Fig. 1. Each of these represents the field flux distribution or "field form" under one of the extremes in the hunting action. Superposing these, as in Fig. 1, it was obvious that the magnetic field was being alternately distorted in one direction and then the reverse, just as if the armature magnetomotive force were reversing. This set of curves explained many things. It was the study of these that soon led to the correct solution of the hunting problem. The writer attempted to do some figuring on the armature magnetomotive forces required to produce the distortions shown in Fig. 1, and while doing this, it occurred to him that as the larger

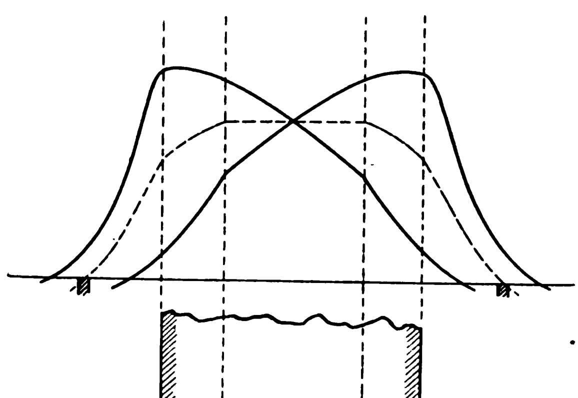

Fig. 1

part of the flux changes were at the edges of the poles, and as the poles had a very considerable "bevel," it might be possible to put a heavy copper plate under each pole edge, which would act as a secondary or "damper" to lessen or minimize the flux changes. At the same time it was recognized that a closed circuit around the field pole itself had a steadying action, as indicated by the tests. In consequence, the writer then proposed that a heavy copper plate or damper, such as shown in Fig. 1, be placed on the pole tips of a converter to see whether it would affect the hunting. In the latter part of 1896 a damper of this type was fitted on one of the Niagara exciters, which, as said before, were utterly inoperative when installed in the Niagara plant. Immediately after this modification, this exciter operated with entire satisfaction as a converter and all hunting disappeared. Obviously, therefore, this was a revolutionary improvement. Immediately plans were made to install such dampers on other machines already built or building, and in each case hunting was overcome. This therefore, was the origin in this country of the damper on synchronous converters, although the later types have departed considerably from this early form.

Meanwhile, however, various other devices to lessen hunting were being tried by other people, as well as the Westinghouse engineers. Among these was the use of a heavy flywheel on the converter, both of flexibly and non-flexibly driven types. The non-flexibly driven flywheel apparently was not entirely effective. The flexibly driven flywheel was to a certain extent effective, according to statements at that time, although the writer had no personal experience with this construction.

Meanwhile, the General Electric Co. seemed to be getting along in a fairly satisfactory manner without any dampers, but the real reason for its better success was apparently not fully appreciated at the time. Its 25-cycle converters at that time were built with solid steel poles, like its d-c. generators, and it was not recognized at first that these in themselves furnished enough damping capacity for most of the 25-cycle machines. In fact, in discussing synchronous converters at a meeting at Niagara Falls in 1897 the Westinghouse engineers took the position that hunting was due, partly, to discrepancies in wave form between the converter and the generator, whereas the General Electric engineers contended that it was due, partly, to the use of two-phase converters, instead of three-phase, as they had no hunting with their three-phase machines. Both of these claims had to be discarded, on later evidence. Recalling this discussion some years later in a reminiscent conversation, Dr. Steinmetz told the writer how his associates and himself had "fooled" themselves into thinking that three-phase converters would not hunt and then, all at once, they discovered, when they used laminated poles, that the three-phase machines would hunt just as badly as the two-phase.

Economical Power: The Strongest Agent for Maintaining Supremacy in World's Trade

BY W. S. MURRAY
Consulting Engineer, New York

I AM not fearful of being misunderstood when I say: "Proud as I am of my country, I challenge the denial that we have been a profligate and wasteful nation in the extreme. Drunk with the wealth of our natural resources we have eschewed their conservation and rolled in a criminal debauch of their treasure." These are strong words, but I deliver them to strong men.

The remarks I have made are a fair foundation upon which to stand in bringing to your consideration the application of these principles to a specific plan which has for its central idea the saving to the nation of $300,000,000 annually, the construction of a regional plant to supply the power demand in a territory that may well be described as the finishing shop of American industry and a release to the railroads from the hauling of 50 per cent of the coal now transported, which amount, by virtue of improper power generation and distribution, is literally thrown away!

A few years ago in Logan County, West Virginia, scattered about on its mining properties there was installed a total of 4000 h.p. in boilers to supply the power requirements. Go there today and you will see one central electric station supplying the same demand with a boiler capacity of 500 h.p. Electric wires have been substituted for the steam mains. So great was the diversity factor of power required at the mines that the single central station is capable of furnishing with 500 h.p. what it took 4000 h.p. to accomplish with the scattered plants. A ratio of 1 to 8, and why? Because the central station generated its power at maximum efficiency and furnished all the power required from one transmission bus. Three mines might each have required 200 h.p. but their demand did not come at the same time. I cite this case as it is, in a way, comparable with the situation that now exists in a territory between Boston and Washington and inland from the coast averaging 100 miles. In this belt, to satisfy the industrial demand there is an installed machine capacity of 10,000,000 horse power. Two-thirds of this demand is for industries, such as: Iron and steel, foundry and machine, textile, lumber, pulp and paper, flour and grist, car shops, rubber, automobiles. The horse power in steam locomotives totals 7,000,000 and the combination of these two great classifications of power requirement offers unexampled opportunity in the application of diversity factor; that is power delivered from the same source to different points at different times.

It has been said that the electrification of the New Haven road was a well conceived and well executed engineering project. As the electrical engineer in charge of this work, some credit has been transferred to my shoulders, and in using the word transferred I do so advisedly, for doubtless much credit was transferred that did not belong to me. That the system has been accepted by the Swiss people as standard for its government roads, and that the Pennsylvania road has installed it on its main line between New York and Philadelphia, is assurance enough that the initiative of the New Haven engineers was based on sound reasoning.

The great lesson the New Haven electrification taught me was not how the catenary wires should be strung over the propulsion rails, but what the economic results are, now that the catenary wires are there.

My message to you today is that we save this $300,000,000 yearly loss, and it can be done by means absolutely within our power, if we but demand that it be done. I do not so construct that sentence to indicate that there is a single person, company or corporation who would stand in the way of such a procedure. Indeed the plan which I shall unfold to you has the hearty endorsement of the engineering and technical press and such societies as the Boston branch of the A. I. E. E., the National Electrical Light Association and now Engineering Council.

I have such enthusiastic support from those so well qualified to pass upon the matter that it is with these encouragements I am brought to you today to promulgate ways and means of bringing the matter to a definite focus looking toward congressional approval and procedure.

The New Haven electrification has shown beyond peradventure of doubt that its passenger, freight and switching wheels can be turned by electricity for less than half the amount of coal expended for steam locomotive operation, and this result is obtained using a source of electrical power, the operating efficiency of which is only one-half that contemplated in the plan to be proposed. The cost of maintenance of steam locomotives is conservatively double that of electric locomotives ton for ton on drivers. These are the two great economies to be secured in the electrification of heavy traction roads. A third economy is that secured in the ability of the electric locomotives to develop greater tractive efforts and speeds than the steam

**Address before the Connecticut Chamber of Commerce, November 19, 1919.*

locomotives, and by so doing consolidate trains with consequent reduction of train-miles, which is an item of great economic value under operating expense.

What has been said about the railroads can be said with even more telling effect about the industrial plants. From the figures preceding it is clear that there is a clean-cut coal saving of four to one if the railroads are operated by electricity. The saving as between electric and steam drive in factories is as high as ten to one; and again there appears, as in the case of the railroads, the greatly reduced cost of maintaining electric versus steam equipment in the factories.

The present load factor of this great regional demand for power is not more than 15 per cent. This means that for every 15 h.p. required, 100 h.p. is installed; whereas in the plan to be proposed the load factor can be increased to 50 per cent or more. Load factor is the ratio of the average load to the maximum. Today, due to the improper form of power generation and distribution, for every ton of coal burned another is wasted—literally thrown away.

By the construction of high-powered, high-economy tidewater steam and hydroelectric stations and steam stations erected at the mouths of mines, within the territory named, all interconnected with a super-power transmission system, using also the large plants now in existence in the larger cities such as Boston, Providence, New York, Philadelphia and Baltimore, there will be integrated one great regional zone, inherent to which will be the three great adjuncts of economical power production, *viz:* High load factor, low coal consumption and continuity of power production (due to an established breakdown service between power centers).

In this presentation it should be borne in mind that between Washington and Boston the contribution of water powers to the regional plant will be but a small percentage of the whole; steam plants at tide water and at the mouths of mines carrying the load up to 90 per cent of the total developed power. However, as the super-power line later is extended, north from Boston and south from Washington, these extensions will reach into the Northern and Southern water power districts and the percentage of water power generated will be increased.

Forgetting now for the moment the yearly savings of $300,000,000 to be secured by the above means let us view the matter from a transportation standpoint. Already the West is reaping its wonderful economic benefits from its developed water powers, while we in the East have but to look out of the windows of our train to see our sidings, our yards and even our main lines clogged with coal cars. Strings of empties and loaded coal cars are actually claiming 40 per cent of the cargo space devoted to transportation. The railroads are burdened with it and would hail a release. This is exactly what the Super-power system would give, for by its installation there would be created what might be termed a "common carrier for power." The railroads in the zone contemplated would be relieved of the necessity of hauling its 4 to 1 inefficient power on its own rails and those roads hauling coal to the proposed electrified zone would enjoy also, pro rata, the automatically created space, for new and higher priced commodities.

Preferred routes from the mines to the sea would be established for coal-bearing roads, and ocean tugs and barges would thus take the place of locomotives and cars for the supply of coal to the central electric station located on tide water. Can it not be well said since we refine oil and ore that we should refine coal? Power is minimum in bulk and maximum in efficiency of use when it is in the form of electricity.

Power is essential to railroads and industries. Without it all wheels must cease to turn. We have 75 years of anthracite coal left to us even if we do not increase the rate at which it is being mined today. We have leaped from 100,000,000 tons of bituminous coal per annum in the last twenty years to nearly 600,000,000 tons, and our Ohio, Illinois, Pennsylvania and Virginia fields are being rapidly exhausted. Cost, due to future location and increased transportation, is on the upgrade and there is no summit to the grade.

Our merchant marine is now building to carry the products of our industrialism, an expansion of which for this country is imminent. If we are to maintain a high standard of American wage and living and our supremacy in the world's trade, its guarantor must be economical power; I mean cheap and reliable power.

The thought which I am anxious to leave with you is that anyone who associates with this project the idea that it has even the lightest shade of local color is wrong. The real thought being that it is one of broad, National scope.

The West is indeed fortunate in the present development and opportunity of further development of her great water powers, and is thus not dependent upon fuel as a base for power production, while we in the East, mindful indeed of the few accessible water powers which will be unquestionably developed, know they represent less than 10 per cent of the total power requirement.

Further, here in the East, due to the present improper form of power generation and distribution, our railroads are congested with coal, only to be wasted and thus be non-productive of power. Is it not therefore a fair cry to ask National legislation which will bring about a high efficiency of power production and permit the coal now wasted in the East to flow to the Middle West for its needs, and by such a distribution make an equitable adjustment in the matter of power production over the whole country?

Many with whom I have discussed the super-power plan have inquired into the matter of what would be the status of the present companies dispensing electrical power, and have followed up their inquiry with regard to the method which would be pursued in financing the

Super-power system. These, of course, are two very important questions. In the case of the first, the answer is that the present companies would maintain their present entities, carrying all their present franchise rights. Their legal status, so far as I am able to see, would not in any way be modified. Indeed, they would more surely become what they would like to be, namely, distributors of power. The districts in which they operate would receive power in bulk from the Super-power system either or both at the points of their present central stations, and substations to be erected —the latter location being in conformity with the highest degree of economic distribution.

As in the case of the local distributing companies, the Super-power system would be entirely individual to itself, and so financed; its object being the generation and transmission of power to the distributing companies with the sole object of getting that power to them at the lowest cost of production consistent with the highest degree of continuity of service.

By far the most important immediate consideration is the investigation Secretary Lane has proposed to Congress by which will be determined the amount and location of waste in this Northeast Atlantic Seaboard Zone, and in the report to be written under the auspices of the Department of the Interior there will be developed engineering and construction plans necessary to its saving.

Now, with regard to the second question, that of financing, a regional plant of the character I have described, it will require the expenditure of a very large sum of money, which however simply points to a truth, the knowledge of which is yours, that we are not only upon the eve, but in the realm of far larger things than have concerned us in the past. Yesterday we were willing to spend a million dollars in construction to save one hundred thousand a year. Today we are ready to spend a billion to save a hundred million a year.

It is my belief that if by this investigation it is proved that in the zone above described there is going to waste $300,000,000 a year, and a perfectly practicable plan is ready at our hands, by which its saving can be effected, there will be no question as to whether it can be financed, but rather what will be the best method of finance to pursue.

What I have had to say should not be construed as any criticism of present central station practise. The people of this country are deeply beholden to those interests who, through their central stations, produce and distribute power so economically. Every time I see white steam rising from the exhaust of some small isolated plant I know that that plant is contributing to the waste we are discussing, and would be reduced if power were delivered to that plant direct from the lines of a large central station. Too often indeed have politics entered into the decision of public commissioners, whereby the central stations' interests have been unwarrantedly attacked and grievously hurt. The introduction of the Super-power system is but to carry on to higher efficiency the work so splendidly begun by the central stations. In a word, it is the great untouched regions in which power is *produced wastefully* which now offer themselves as a market to the Super-power system; the new stations to be built combining with the existing larger plants to furnish that power.

This is, you may say, such a tremendous thing. How will we ever be able to accomplish it? It rather takes your breath away and yet, gentlemen, it is as simple as it is large. There is not one detail in its assembly that has not been thoroughly tried out from an engineering, construction and operating standpoint. We have all the materials, we have the location, we have every room rented in advance—it is time to construct the building! We can liken it to the machine shop starting with its little 20 h.p. engine and boiler. Trade prospers and an extension to the building is made with another engine and boiler and again another extension, but all the while the increments are of the order of the first plant, carrying with them their inefficiencies in power and method of the early years. Then suddenly the owners realize that their business and power requirements are sufficiently large to wipe out seven-eighths of their original plant and build a new shop, employing the principles governing the new one-eighth. The case cited, small and insignificant as it is, is a perfect simile to the Super-power system. Throughout the zone I have described there is a demand for one-third of the total industrial horse power produced in the country, and but a small per cent of our railroad tonnage is moved by this highly efficient power agent, electricity, and so as the increments of power have been added in this territory to meet the ever growing demand, and now greatly enhanced by this burst of industrial expansion, in turn requiring increased railway facility, we find ourselves with a plant of scattered boilers, as in the case of the Logan County, W.Va. mining district, only five thousand fold magnified. The greatest assembled load of the world has grown up under this inefficient supply! It is ready now to be transferred to the busses of a regional system whose guarantee will be continuity of service and a saving to the people of $300,000,000 a year. In that presentation I ask you if the case, large as it may seem, is not a simple one.

The United States Geological Survey, Department of the Interior, the office of which is administered by Dr. George Otis Smith, presents under October 29, 1919, some very interesting statistics concerning the division of power resources of this country, and which concerns the relative production of electric energy by water versus fuel.

Taking the month of March, which is one of the maximum months of water power production, the combined water power output of central stations supplying power for public utilities in the following states:

Rhode Island, Connecticut, New Jersey, Pennsylvania, Delaware and Maryland was approximately 119,500,000 kw-hr., while the energy produced by fuel was 498,000,000 kw-hr. This means, therefore, that water produced less than 20 per cent of the total energy.

I have purposely eliminated the State of New York, as the water power production for that state is confined chiefly to the section of the country immediately adjacent to Niagara Falls. Should this state be included, the ratio rises to 30 per cent but even with Niagara Falls included it is to be noted that the water power production is less than a third.

Taking a dry month, and again excluding New York State, the ratio of water power production sinks to less than 10 per cent, and if all the industrial and railroad wheels in the zone contemplated were turned by electricity the *average* water power available would be considerably less than 10 per cent of the whole. It is interesting, too, at this juncture to say that while nearly *100 per cent* of the load in this zone could be handled by electricity, we find today that less than *33 per cent* of it is being so handled.

I am sure you will be amazed to know that in the New England States, and New York, Pennsylvania and New Jersey alone, there is shipped into this territory 37,000 tons of coal daily for public utility central stations.

The total coal tonnage used by all the electric power plants in this country, engaged in public service, is only 95,000 tons per day, and thus in only a part of the zone we are discussing, representing less than 5 per cent of the total area of the United States, there is required 40 per cent of the total amount of coal so used.

Again, another point of view: To ship this amount of coal into this district requires over 800 cars in and out every day. This would represent a solid train of coal cars seven miles long. Now you have but to visualize this train split up into units, varying say from one car to ten, being switched in the yards, on the sidings and many times on the main lines. Does not an arrangement so inefficient, so clumsy and so costly fairly make one cry out in despair for a unified common carrier system of power, especially when it is known that every day but adds to this confusing congestion?

All this points to the inevitable conclusion that the power for this great finishing shop of American industry must in a large measure be furnished with fuel as a base. Are we willing wantonly to blast the hopes of posterity? Is not our duty plainly in sight? Must we not perform? Therefore, I say to you, we must look to remedial methods of power production, which we have at our fingers' ends, to prevent this impending catastrophe.

Please do not conclude from what I have said that we should not develop every waterfall economically within the radius of this Eastern district, and this includes powers which exist on such rivers as the Connecticut, Housatonic, Susquehanna, Delaware and Potomac, and many others between them, of which doubtless their names are unknown to you. As an example of the latter class while acting as Chairman of a committee of engineers during the war, a report to the Government was made on one—the Wallenpaupuck flowing through Pike County, Pennsylvania. Its economy as compared to a steam station of equal capacity, was such that the steam station would have had to be amortized (on an 8 per cent basis) to the extent of $12,000,000, (which, too, happened to be the cost of the hydroelectric station) before it began to compete with the water plant!

Gentlemen, there is no danger or chance of failure in this regional plant to perform. Every engineer in the country whose experience has been of the order of mine, knows where the danger lies; that it is in this drift, drift, drift policy, an attitude of "letting well enough alone" when the "well enough" is in fact a willingness to let this American birthright to supremacy in world's trade be taken away from us and from beneath our very noses; and I say to you New England men, among whom I have lived in affectionate regard, that you are practicing a conservatism locked in the arms of failure.

In the vernacular of the American youth, "You are asleep at the switch." The world has caught up with you, and is passing you. You fought for what you got; now you have got to fight to hold on to it, and you have got to start the fight not tomorrow, but today. One of New England's solid men said to me the other day, apropos of the New England situation and its fine practise of conservatism; "Economical power is the sole remaining means to prevent this finishing shop of American industry from being converted into the playground of American tourists." These, gentlemen, as you know only too well, are not idle words. One has but to read the signs and then predict the result. Power is being produced nearly everywhere more cheaply than in this zone. Yet this zone is the American home of skilled labor. That labor does not wish to migrate, but it will migrate unless you make economical power migrate to it, and the distance it will have to go will not be far with the means now at hand to eliminate this criminal waste.

I feel sure you realize now the immeasurable waste of human and national treasure that is going, on, yet a few among the many will say: Why the cost of power does not represent 5 per cent of my manufacturing cost! The perspective of a man who says that ends one inch from the end of his nose, and he admits in the same breath that the conservation of the Nation's resources is nothing to him. He also puts himself at once in a losing class. Why? Because while electricity *is* the agent of highest efficiency in power application, yet as such it is *nothing* compared to its efficiency as an agent to facility. What this country has got to do to maintain her supremacy in world's trade is to produce, produce, and then produce more. Even if the cost of electricity's application were twice as much as steam

its contribution to the facility of production, in nearly every form, would far outweigh the additional cost. A hundred examples spring to one's lips: In the factory—the individual machine driven tools; on the railroads—the multiple-unit locomotives operated from either end. (The turn table and ash pit are things of the past for the 100 per cent operated electric division).

I saw a sign the other day on the walls of a central power station, it said: "Electricity for Everything." The average manufacturer worries himself to death about his coal pile. Visualize the miserable little coal piles scattered all over this great industrial region. What do they stand for? Congested traffic, throttled production and waste of our national resources. If we practise what was said on that sign what will that stand for? Open traffic, greater production and conservation.

Before closing there are two other aspects I would touch upon under a slogan I offer now for your consideration.

We have spent billions for destruction for preservation now let us spend billions for construction for conservation.

The first: We are the greatest industrial nation of the world. How can we better maintain that supremacy than by giving employment to the millions of our boys that have crossed the sea to maintain the principles for which this nation stood. This plan offers employment in factory and field, and when completed will be the kenetic embodiment of national wealth—a living, active, producing tool, guarding national conservation. *The World's Work* for November, 1919, page 14 (as reading from Mr. Hoover's analysis on page 98) says:

The present high prices both here and abroad are the result of a lack of useful products. During the war economically useless products were produced under great pressure at high costs. The high cost of production still continues and applies to all products. Our old ability to produce cheaply by means of machinery and to pay the producer a wage with which he can keep up a relatively high standard of living is in danger. The wage is high but the purchasing power of it is not. The only solution is to give the producer better tools, better machinery, better management, so that he can increase his product and get more money for it to meet the high prices, and to have the worker give more brains and energy to match this improvement.

The second, Mr. Frederick Darlington, whose excellent work on the War Industries Board is well known, says:

In the central power station business so much of the cost of service goes to pay for invested capital that it is most essential that the interest rates should be kept low which can be done only by making the investment safe, that is; by so regulating rates that principal and interest will be secured. From a national point of view, as effecting the general industrial efficiency of our manufacturing and power-consuming districts, it is relatively unimportant whether the cost of power is one mill or two mills per unit more or less than some established rate, whereas it is of vital importance for the conservation of resources, for economy of production and for general industrial efficiency that the bulk of the power used should be made by central systems as against isolated plants; therefore let us try to get our law-makers and public executives, national, state and municipal, to take the Government point of view, in other words, to think in terms of the war which are also terms of peace from a Government standpoint, and to uniformly and rationally encourage central power development, provide for a just return to capital in electric power business and grant monopolies under regulations that will foster co-ordination and interstate operations.

Especially also would I draw your attention to the proceedings of the National Electric Light Association covering its recent deliberations at the Atlantic City Convention in which will be found the address of Dr. George Otis Smith, Director of Geological Survey. Director Smith's address is a splendid endorsement of Secretary Lane's request for Congress to provide sufficient funds to the Department of the Interior by which an investigation can be made to allocate the losses now sustained and to be inclusive of recommendations covering a power transmission and distribution system by which they may be saved.

This appropriation will come under general expenses of the Geological Survey and be a part of the general civil sundry bill.

If what I have said has appeared to you as reasonable and constructive it would be a pleasure indeed to have your endorsement of it.

DISCUSSION BY E. G. BUCKLAND

President N. Y., N. H. & H. Railroad

In the winter of 1917–18 New England faced a serious coal shortage. There was much suffering, a partial paralysis of business and a threatened stoppage of transportation. We who were responsible for transportation facilities in New England did our best to continue the carriage of freight and passengers and to keep the industries running. We divided our coal piles with our less fortunate neighbors and in some instances our more fortunate neighbors divided their coal piles with us. It was a time when on the other side of the water the war was going against us and on this side it seemed as if nature had conspired to favor the enemy. Now, while this emergency brought out the finest qualities of generous cooperation between industries and carriers yet those who would continue to be responsible for transportation facilities felt that if it were possible a coal shortage in New England should never be permitted to occur again. Coal stands for energy however it may appear, and it is this shortage of power which has seasonally handicapped New England. It had occurred to some of us who have studied this situation that there were possibilities of power and coal conservation which had not yet been developed. I personally knew that Mr. William S.

Murray had given the matter a great deal of thought and after talking with him and likening the situation to the conservation of forests and the conservation of water power in the west, wrote to Hon. Franklin K. Lane, Secretary of the Interior, and asked him if it were not possible to include in his conservation projects one looking to the conservation of power in New England, pointing out to him the possibility of combining unused water power in New England, with power from tide water coal brought to New England ports and unmerchantable coal, developing power at the mines in the coal regions of Pennsylvania and the Virginias. Secretary Lane immediately answered that the subject was one to which he and Doctor George Otis Smith, Director, Geological Survey, had given much thought and that he had already asked for an appropriation to make a general survey of the country looking to the correlation and conservation of all sorts of power. Mr. Murray and I thereupon went to Washington, consulted with Secretary Lane and Dr. George Otis Smith and found that our ideas were at one, as a result of which Secretary Lane has brought the matter before Congress and is asking for authority to make a general survey of the United States and an extensive survey of what he calls the Boston-Washington district, with the idea of reporting the possibilities of marshalling the sources of power and conserving the coal supply.

It has been said that the man who makes two blades of grass to grow where one has grown before is a public benefactor. Obviously a man who in New England can make one pound of coal do what two pounds has done before is even a greater benefactor and even though coal be the largest single item of freight revenue no carrier having the good of the public at heart could afford to oppose a plan which cuts the cost of power in New England. For every dollar lost by diminishing the coal hauled there will be more than a dollar gained from the increased traffic on higher class products. New England has long been handicapped by its lack of coal and raw materials. It has a wonderful supply of pure water, a climate conducive to skilled labor, communities where skilled labor finds congenial homes and fine educational institutions for the upbringing of families, but unless it can hold its own in the prices of its products all of its advantages will be overbalanced by its burdens, and the greatest of its burdens is its lack of power supply.

Therefore, the question confronting railroads and industries in New England has ceased to be the usual issue between shipper and carrier but has become a question as to what the carrier can do for the shipper and what the shipper can do for the carrier in order to keep New England's industrial supremacy from leaving and New England from being turned into a rich man's playground. We believe that with New England's proximity to tide water, with its undeveloped water powers, and with the enormous economies to come from developing electrical current from large central stations and hydroelectric developments it can continue to compete in the markets of the United States as well as the markets of the world. It is to that end that this group should recommend that the Chamber of Commerce further the efforts now being made by the Secretary of the Interior to obtain an intelligent idea of the savings which will result from a survey of the sources of power between Boston and Washington with the idea of contributing them to a common channel and distributing to consumers within that region.

DISCUSSION BY CHAS. F. SCOTT

Professor of Electrical Engineering, Yale University

The statement has recently been made that the limit to industrial expansion is likely to be in transportation facilities, that is, in the ability to supply raw material and distribute products. The railroads have been hard pressed; war requirements exceeded their capability and the Government took over the railroads and employed the methods of unification and coordination which it had formerly prevented the railroads from adopting. The ton-miles of freight in the United States was more than three times as great in 1916 as it was in 1900. If industrial expansion is to continue, railroad facilities must be increased and the way to increase them in congested regions is by electrification. This not only increases the traffic capacity of tracks and terminals but it reduces the coal required for railroad operation. A general electrification of industry will further reduce the coal to be transported for industry thereby releasing the equipment for industrial freight.

Mr. Murray's paper may be reinforced in two points; first, as to the increased usefulness of electrical power in industry, and second, as to the future demands.

New England is a manufacturing community without raw materials or coal. Its asset is the skill of its people. The prime business is devising and operating machinery which uses power. Excellence and economy depend largely upon the kind of power available. Electric power repeatedly proves its superiority in industry for lighting, for motor application, for furnaces and ovens, by reducing costs, improving quality and increasing output. The two fundamental requisites of New England industry are electric power and transportation. The universal power system is the key to both.

Mr. Murray's statements of large savings refer to present conditions; they do not include future growth. Pre-war curves show a growth in industry in which the primary horse power in industries in the United States has increased from 10,000,000 in 1899 to 22,500,000 in 1914. In the same period the horse power in New England and the middle Atlantic States doubled. The proportion of this power applied electrically has increased in far greater ratio, doubling in about five year periods. This means, if the curves of recent progress are continued during the next decade, that in

ten years the total power will be on the order of double what it is now and that the electric power will increase four fold. This is a matter of enormous magnitude and of vital concern as a factor in production, which was never more greatly needed than now. The economies in the future should greatly exceed those which Mr. Murray estimates would be possible now. There is every reason why a broad gage general survey of the problem should be undertaken at once.

If the use of electric power continues to increase at its past rate and is double in five years from now, then the electric energy to be produced during the next five year period will aggregate a total number of kilowatt-hours equal to the total which have been produced in the past forty years. It is certainly worth while to determine what the demand probably will be and to plan the best way of supplying it.

DISCUSSION BY SAMUEL FERGUSON

Vice-President Hartford Electric Light Co.

I wish to emphasize one point touched on by Mr. Murray, namely, the need that the Connecticut representatives at Washington should be made to realize that we are interested in this plan and approve Secretary Lane's request for an appropriation of $200,000. for a survey and report; and I hope that the resolution committee will favorably report a resolution to that effect at the general meeting tomorrow. In addition, our congressmen should hear from individuals.

The outline as given by Mr. Murray is a wonderful conception, but probably its very vastness is discouraging to some on account of the legislation and financing, which apparently must first be done: To me, this is not so, because if every section of New England keeps this plan in mind as an ultimate solution, and if all central power companies and manufacturers make their investments for power production or power utilization, in such a manner that each will eventually become an integral part of the system, the final consolidation will become a relatively simple affair.

In answer to Mr. Wright's question as to what gain there could be to manufacturers in Hartford, I would simply state as one instance of gain, that at present about 13,000 h.p. of surplus station capacity is installed there and held idle from one years' end to the other, simply as a reserve in case of failure of other apparatus. If, then, the Hartford plant were connected to the super transmission system, this investment when not needed locally, could be used to furnish current to the system, thus earning its fixed charges, rather than as at present, having the fixed charges of the spare investment absorbed in the local price of power.

As an apt illustration, three hours ago a serious accident happened to the Waterbury power station. By quick work and emergency connection, the above mentioned reserve capacity is now being used to supply part of the Waterbury deficit. Under Mr. Murray's plan there would have been no interruption, as the inter-connection would have been such that a failure in one part would be automatically taken care of by the next section.

CANADA'S LARGE PROJECT

OPERATING the largest shovels in the world and reversing the flow of the Welland river, the Hydro-Electric Power Commission of Ontario is carrying on what is said to be the most extensive engineering project on the North American continent—and that practically without the use of steam.

To get water to the new power house to be built above Queenston, the Commission will utilize four and a quarter miles of the river. This will cause that stream to flow backward and take water from the Niagara river. The commission expects to have the new plant working by 1922. The project will cost around $27,000,000.

Two miles above the brink of Niagara Falls, a steam dredge is gnawing away at the channel of the Welland river. This dredge and the attendant tugs are the only equipment engaged on the improvement that are not owned by the Commission. They and seven switch engines are the only steam-propelled apparatus used on the development.

Drills boring through the rock of the canal right of way are operated by air, electrically compressed. Electrically-controlled clamshells swung from aerial cableways, huge electric shovels, electric trains and electrically operated rock crushers show how the Genie of Electricity has been made the slave of the engineer.—*Cleveland Engineering.*

GIFT OF A BUST OF FRANKLIN

A welcome addition to the artistic possessions of the headquarters of the Institute has been made by the gift of a tinted plaster bust of Benjamin Franklin, by past president T. C. Martin. The original of the bust in marble is in the collection of the Pennsylvania Academy of the Fine Arts, at Philadelphia. It was executed in 1777 by Jean Jacques Caffieri, sculptor to the King of France and professor in the Royal Academy of Painting and Sculpture; and for many years was attributed to Ceracchi, under circumstances which are very interestingly set forth in "Jean Antoine Houdon" by Charles Henry Hart and Edward Biddle, who describe in detail the various differences between the Caffieri bust and that by Houdon, to which they prefer it for technical and artistic reasons. Caffieri was also the sculptor of the tablet to the memory of Major General Richard Montgomery, in the portico of St. Paul's Church, New York City, in vari-colored marbles. This, the oldest monument on Manhattan Island, was erected some little time after the glorious death of Montgomery at the capture of Quebec. It is interesting to note that the records of the Pennsylvania Academy still attribute the bust to Ceracchi.

Starting Conditions of Synchronous Machines

BY ALFRED HAY

Professor of Electrical Technology, Indian Institute of Science

AND

F. N. MOWDAWALLA

INTRODUCTION

IN view of the growing popularity and importance of the synchronous motor as one of the standard types of motor available for power distribution purposes, and its increasing use as a means of improving the power factor of a load, no apology seems necessary for a paper containing a detailed study of the behavior of such a motor during what has always been regarded as a somewhat critical period—*viz.*, the period when the motor is being accelerated from rest to synchronous speed. The subject is by no means a new one, and has already been dealt with by several writers, not, however, in a manner sufficiently thorough and exhaustive to make further contributions to it superfluous, and one of the main objects of the present paper is to explain a number of hitherto somewhat obscure points, and to draw attention to others which have not previously been noticed.

REVIEW OF PREVIOUS WORK ON THE SUBJECT

The earliest paper specially devoted to a study of the starting conditions in synchronous machines appears to be one read in 1912 before the American Institute of Electrical Engineers by C. J. Fechheimer.[1] In this the author, after some general introductory remarks, gives an account of experiments made to determine (1) the relation connecting the starting torque with the impressed potential difference under various conditions and (2) the variation of torque, current and power factor with speed, while the rotor is accelerated from rest, a constant potential difference being maintained across the stator terminals. The experimental results are embodied in an interesting series of curves. Among the questions discussed by the author are the desirability or otherwise of keeping the field circuit open during the acceleration period, and the tendency of certain synchronous machines to run in the neighborhood of half the speed of synchronism. Fechheimer's paper gave rise to a very interesting discussion.

In 1913 E. Rosenberg[2] read a paper before the Institution of Electrical Engineers, on Synchronizing machines in which he considered, among other things, the occurrences during the starting period, and discussed in some detail the behavior of the machine towards the end of the acceleration period, just before it is pulled into synchronism. It may be mentioned that in the discussion on Fechheimer's paper, it was stated by B. G. Lamme that it was "difficult to see just what is going on in the motor at the instant it pulls into synchronism." So far as the authors are aware, Rosenberg's was the first attempt to furnish a detailed explanation of the action in question.

The next contribution to the subject is one by F. D. Newbury, in the form of a paper read before the American Institute of Electrical Engineers in June 1913.[3] The main interest of this paper lies in the oscillographic records which are given of the starting period.

In December 1917 the authors of the present paper published, in the *Journal* of the Indian Institute of Science, an account of some experimental investigations of the occurrences during the starting period of a synchronous machine, and a full theoretical discussion of the type of induction motor whose stator is supplied with polyphase currents, and whose rotor is provided with a single-magnetic-axis winding. As will be seen later, the theoretical results obtained explain in a satisfactory manner certain striking peculiarities exhibited by the machine during the starting period.

The most recent addition to the literature of the subject is an article by Theo. Schou in the *Electrical World* of April 6th, 1918 (Vol. 71, p. 714). In this article the author points out that a satisfactory self-starting synchronous motor should partake of the characteristics of both an induction motor and an alternator, and should present features of design intermediate between these two classes of machines. He accordingly advocates the use of a shorter air gap and longer polar arc than are customary in alternators of standard design. He further suggests the use of materials having a pronounced skin effect for the squirrel-cage windings of self-starting synchronous motors[4] and points out the advantages of fractional-pitch windings in reducing the troubles arising from dead points.

Presented at a joint meeting of the Institution of Electrical Engineers, and the American Institute of Electrical Engineers, Calcutta, India, January 2, 1919.

4. The utilization of the skin effect in the rotor conductors of induction motors was patented by H. M. Hobart in 1900.

Torques Concerned in Accelerating the Motor and in Pulling it into Synchronism

The self-starting synchronous motor is accelerated and finally pulled into synchronism by the action of a number of torques, differing widely from each other, and the resultant effect of which will largely depend on their relative importance. Cases may arise where, owing to the preponderance of a certain type of component torque, it may be impossible to get the machine to run up to synchronous speed. Again, the torques concerned in the initial acceleration of the rotor are quite distinct from the torque which finally pulls it into synchronism. The authors are of opinion that no really clear understanding of the occurrences during the starting period is attainable without a detailed study of the various torques which act on the rotor during that period. It will accordingly be necessary to consider

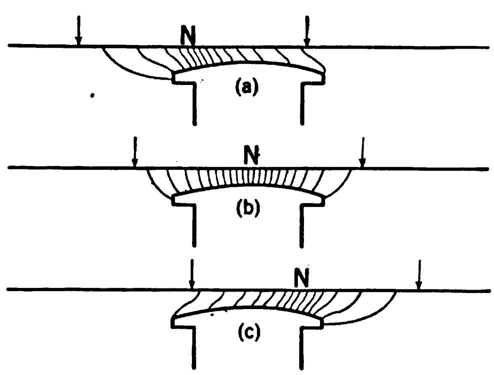

Fig. 1—Flux Distributions for Different Relative Positions of Stator Field and Magnet Poles

the nature of the various torques concerned. These torques may be classified as follows:

1. Torque due to varying magnetic reluctance (synchronous torque.)
2. Torque due to hysteresis.
3. Torque due to starting squirrel-cage or damping coils if present.
4. Torque due to currents induced in the field winding, if this winding is closed.
5. Torque due to eddy currents.

1. Torque Due to Varying Magnetic Reluctance

It is a well known general principle of electromagnetism that any electromagnetic system which includes a movable member tends to assume a configuration which corresponds to minimum reluctance and therefore maximum flux. Displacements of the movable member from the position of minimum reluctance call into play forces tending to restore it to that position. The application of this general principle to the special case of a salient pole rotor, which is acted on by the rotating field of the stator, will be easily understood by reference to Fig. 1. In this figure, three different positions of one of the rotor poles are shown relatively to the stator polar surfaces. The center of the stator polar surface is in each case marked with the letter N. In Fig. 1B, the relative positions of the rotor and stator polar surfaces correspond to minimum reluctance, and from the symmetry of flux distribution it is immediately obvious that there is no tangential pull on the rotor. In Fig. 1A, the rotor pole is shown displaced from the position of minimum reluctance in one direction, and in Fig. 1C in the opposite direction. If we bear in mind that the dynamical stresses correspond to a tension along the lines of force and a pressure at right angles to them, it is easy to see that in Fig. 1A there is a tangential force acting on the pole from right to left, while in Fig. 1C it acts from left to right. If we now suppose that the stator polar surfaces travel past the pole in a direction from left to right, then the successive positions will be those shown in Fig. 1. For every displacement of the stator polar surface to one side of a rotor pole, there will be an equal displacement to the other side, and the forces corresponding to equal displacements in opposite directions will be equal and opposite. Thus the rotating field will exert an alternating torque on the rotor, and the positive and negative half-waves of this torque will be equal. The frequency of the torque will be equal to twice the supply frequency multiplied by the motor slip, and so long as the motor slips, the mean value of the alternating torque due to varying magnetic reluctance will be zero. The only effect of this torque is to throw the rotor into forced vibrations, having a frequency equal to that of the torque. Owing to the large moment of inertia of the rotor the vibrations will be imperceptible for large values of the slip, *i. e.*, during the greater part of the acceleration period. When, however, the slip has become sufficiently small and in consequence the frequency of the torque sufficiently low, the amplitude of the rotor oscillations will become marked, and will increase with decreasing slip.

Summing up, we see that the torque due to variable magnetic reluctance is for all speeds below synchronism an alternating torque consisting of equal positive and negative half-waves, and hence having a zero mean algebraic value. It is therefore quite inoperative so far as steady acceleration of the rotor is concerned, and only produces equal periodic accelerations and retardations, *i. e.*, it causes oscillations of the rotor. The period of these oscillations is determined by the rotor slip, and steadily increases with decreasing slip. At the same time, the amplitude of the oscillations increases.

The graph of the varying magnetic reluctance torque expressed as a function of the speed is shown in Fig. 2A. For all speeds below synchronism its mean value is zero, while at synchronism it is capable of assuming any positive or negative value between definite limits. Since the speed of synchronism is the only speed at which this torque has a value differing from zero, we may conveniently refer to it as the *synchronous torque*.

2. Torque Due to Hysteresis

In dealing with the torque due to varying magnetic reluctance, we have neglected the effect of hysteresis. It now becomes necessary to take this into account. Owing to hysteresis the rotor will tend to retain more or less strongly the effects of previous magnetizations. Thus referring to Figs. 1A and 1C, if hysteresis were absent, the magnitudes of the torques in these two cases would be equal. Owing, however, to the fact that in the position of the rotating field corresponding

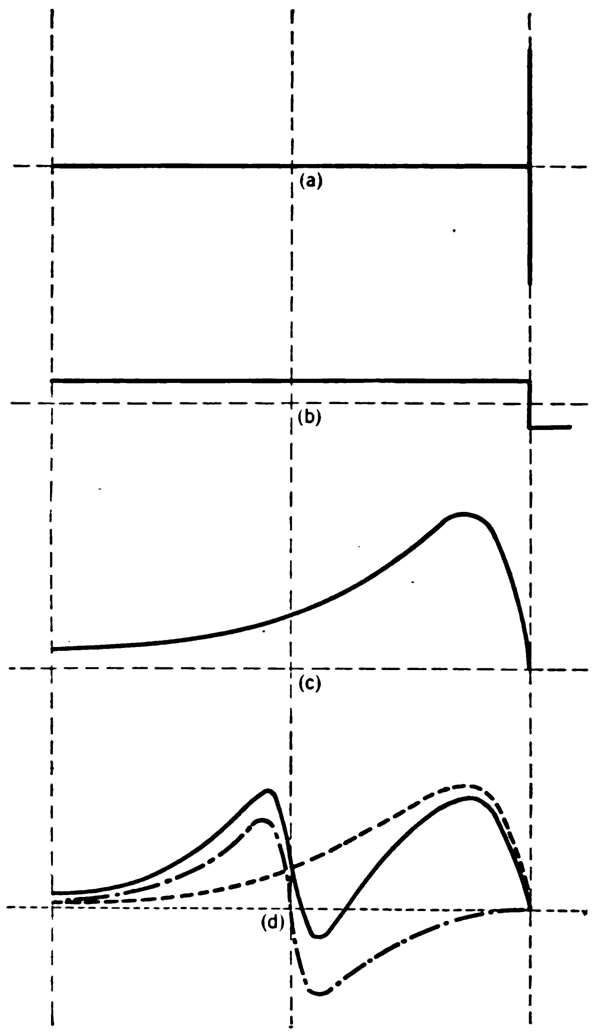

Fig. 2—Torque-Speed Curves

to Fig. 1A the magnetization of the rotor is increasing from a lower to a higher value, while in position Fig. 1C it is decreasing from a higher to a lower value, the actual flux in Fig. 1C will be higher than that in Fig. 1A. The same applies to each pair of corresponding or equidistant positions on opposite sides of the position of maximum flux shown in Fig. 1B. For any such pair of positions, the driving torque is greater than the retarding torque. The effect of hysteresis is thus seen to be the production of a disparity between the positive and negative half-waves of the varying magnetic reluctance torque, the positive half-waves being uniformly larger than the negative ones. This effect is equivalent to raising the magnetic reluctance torque waves above the axis of time, *i. e.*, to the addition of a steady driving torque to the alternating magnetic reluctance torque. The torque due to hysteresis is thus seen to be a steady driving torque and is instrumental in producing acceleration of the rotor. It is to be noted that, assuming the flux per pole to remain constant during the acceleration period, the hysteresis torque has the same value for all speeds below synchronism. If the speed were made to pass through synchronism to higher values, the hysteresis torque would undergo reversal at synchronism.

The graph of the hysteresis torque as a function of the speed is shown in Fig. 2B.

3. Torque Due to Starting Squirrel-Cage or Damping Coils if Present

Little need be said about this torque, which may be called the induction motor torque, as everybody is familiar with the relation connecting the torque and speed of an induction motor. The squirrel-cage of a self-starting synchronous machine forms the rotor winding of an induction motor whose stator windings are represented by the armature; the relation connecting torque and speed will be of precisely the same nature as in an induction motor.

The graph of this torque as a function of the speed is of the well-known form shown in Fig. 2C.

The method of varying the torque-speed curve of an induction motor by the introduction of resistance into the rotor is also well known. The effect of introducing resistance is to cause a shearing of the torque speed curves backwards towards the origin, the maximum torque remaining unaffected in value, but occurring at a lower speed. If a very powerful torque is necessary at starting, it is advisable to use a high-resistance squirrel-cage. On the other hand, with such a squirrel-cage the speed to which the motor finally settles down corresponds to a large slip, and this, as will be seen later on, makes it more difficult to pull the rotor into synchronism. The ideal arrangement would be one in which the squirrel-cage resistance at starting is such as to give maximum torque, the resistance then automatically decreasing with increase of speed in such a manner that at each speed maximum torque is maintained, until finally the lowest possible resistance is reached, corresponding to a very small slip. The use of the skin effect in conductors for automatically decreasing the rotor resistance with increasing speed has recently been proposed by Theo. Schou.[5]

4. Torque Due to Currents Induced in Field Winding, if this Winding is Closed

If the field winding be closed, the currents induced in it will give rise to a torque, and a careful study of the nature of this torque is essential to a clear understand-

5. Loc. cit.

ing of the occurrences during the starting period. The armature of the machine may again be regarded as forming the stator winding of an induction motor, of which the rotor winding is represented by the field coils. There is, however, this very important difference between the starting squirrel-cage and the field winding: the currents induced in the squirrel-cage are capable, according to their distribution in space, of giving rise to a field whose magnetic axes may occupy any positions whatsoever relatively to the center lines of the field poles; but the currents induced in the field winding can only produce a field whose magnetic axes are coincident with the center lines of the field poles. This is conveniently expressed by saying that the field winding is a "single magnetic axis" winding; because it can only produce a field having a single definite set of magnetic axes, namely, those corresponding to the center lines of the salient poles. Now a motor having a polyphase stator, but a single-phase or single-magnetic-axis rotor, exhibits certain striking peculiarities which differentiate it sharply from a motor in which both stator and rotor windings are polyphase. The earliest reference to this type of motor which the authors have been able to find occurs in a paper by H. Gorges[6]. Since such motors are not ordinarily used in practise, their characteristics do not seem to be very generally known, and have only occasionally been referred to. A complete analytical theory of this type of motor will appear in the A. I. E. E. TRANSACTIONS, for 1919. The torque-speed curve of such a motor is shown in Fig. 2D, and its most striking characteristic is the torque reversal which occurs over a certain range of speed in the neighborhood of half-synchronism. The analytical theory of this motor, is somewhat complicated, but the following general explanation based on a paper published in 1898 by F. Eichberg[7] may be useful. The currents induced in the single-phase rotor winding by the rotating field of the stator give rise to a field which, relatively to the rotor core, is a simple alternating or oscillating field. By a well-known transformation this oscillating field may be replaced by two equal and (relatively to the rotor core) oppositely rotating fields, the crest value of each rotating field being half the maximum crest value of the oscillating field. Now if the slip of the motor be s and if its speed of synchronism be denoted by n, the frequency of the rotor currents will be $s\,f$, where f is the frequency of supply, and the speed of its component rotating fields relatively to the rotor core will be $s\,n$, the speed of the rotor in space being $(1 - s)\,n$. Regarding the direction of rotation of the rotor as positive, the speed of one of the rotating fields relatively to the rotor core is $+ s\,n$, while that of the other is $- s\,n$. Hence the speeds of the rotor rotating fields *in space* are $s\,n + (1 - s)\,n = n$, and $- s\,n + (1 - s)\,n = (1 - 2\,s)\,n$. The interaction between the stator field, and the first rotating component of the rotor field, whose speed n in space is the same as that of the stator field, gives rise to a torque in every respect similar to that of an ordinary induction motor with polyphase windings on both stator and rotor. The second rotating component of the rotor field, whose speed in space is $(1 - 2\,s)\,n$, is clearly incapable of reacting with the stator field in such a manner as to give rise to a resultant torque; for, owing to the difference of speed, the relative position of the fields is constantly changing, periodically passing through a succession of cycles during each of which the average algebraic value of the torque is zero. Although incapable of torque production by interaction with the stator field, the second rotating component of the rotor field is capable of giving rise to a torque by different kind of action. In sweeping across the stator conductors, it induces in them e.m.fs. of frequency $(1 - 2\,s)\,f$, and these produce currents of the same frequency in the stator windings and the circuit external to them (represented by the mains and everything connected across them generators, motors, lamps, etc.). Since the total impedance external to the stator windings is extremely small in comparison with that of the windings themselves, the result, so far as the currents of frequency $(1 - 2\,s)\,f$ are concerned, is nearly the same as if the stator windings were short-circuited. The currents give rise to a rotating field whose speed $(1 - 2\,s)\,n$ in space is the same as that of the inducing rotor field, and the interaction of these two fields whose relative space position is invariable, results in the production of a torque. To fix ideas, we may think of the second component of the rotor field as produced by a polyphase winding on the rotor supplied with suitable polyphase currents having a frequency $s\,f$, and of the rotating field due to this as inducing currents of frequency $(1 - 2\,s)\,f$ in the stator windings. The arrangement would then be equivalent to a polyphase motor whose primary is represented by the rotor and whose secondary is represented by the stator. The slip of this imaginary motor would be $(1 - 2\,s)$ and so long as s is less than $\frac{1}{2}$, the slip and torque would be positive. Zero slip would occur at $s = \frac{1}{2}$, *i. e.*, at half the speed of synchronism. Beyond this point the slip and torque would assume negative values.

The resultant torque of the motor would be obtained by taking the algebraic sum of the torques due to the two oppositely rotating components of the oscillating rotor field. This torque is represented by the full line curve in Fig. 2D, the dotted and chain-dotted curves corresponding to the component torques due to the two rotating components of the rotor field.

If we suppose that the torque arising from the current in the field winding is large in comparison with the other torques acting on the rotor, so that the dominant effect is that due to the field winding, then it is evident that the torque reversal which occurs at half-synchron-

6. H. Gorges: "Ueber Drehstrommotoren mit verminderter Tourenzahl, *Elektrotechnische Zeitschrift*, Vol. 17, p. 517 (1896).

7. F. Eichberg, *Zeitschrift fur Elektrotechnik* (Wein), Vol. 16, p. 578 (1898).

ous speed will tend to make the machine run in the neighborhood of that speed, and it will then be impossible to run the machine up to full synchronism.

In the discussions which have taken place regarding the tendency of the machine to settle down to a speed in the neighborhood of half-synchronism, erroneous views have frequently been expressed. Some engineers appear to hold the opinion that the machine *locks* into exact half-synchronism. As we have seen, the speed to which it settles down, although near half-synchronism, is not definite, and may, according to the special circumstances of each case, be anywhere in the neighborhood of that speed. It is no more correct to say that the machine locks into half-synchronism, than it would be to say that an ordinary induction motor locks into full synchronism.

5. Torque Due to Eddy Currents

If the field structure is laminated throughout, the torque due to eddy-currents will be insignificant. The case is otherwise, however, with solid field poles in which large eddy-currents may arise. If we were to imagine the rotor replaced by a solid cylinder of conducting material, then the rotating field of the stator would give rise to rotating eddy-current sheets in the conducting cylinder, and the axes of such current sheets[8] would follow the axes of the rotating stator field. There would in this case be perfect freedom of motion of the axes of the current sheets relatively to the rotor, and this condition is closely approximated to in an ordinary squirrel-cage winding. If we next suppose that the conducting cylinder is cut up into a number of sectors by radial barriers of insulating material, then the freedom of motion of the axes of the current sheets relatively to the rotor would be largely destroyed, and these axes could only swing through an angular distance not exceeding the angular width of a sector. Now this is approximately the case corresponding to a salient pole rotor with solid poles. In such a rotor, owing to the restriction imposed on the free development of eddy currents by the relatively large spaces between the field poles, the axes of the eddy currents can only travel through a relatively short distance. If the axes could not travel at all, the arrangement would be identical with that of a rotor having a single magnetic axis winding; while if the axes could travel with perfect freedom, it would be identical with that of a squirrel-cage rotor. Hence we see that the torque due to eddy currents in the solid field cores will partake partly of the nature of the torque due to a single magnetic axis rotor winding, and partly of that due to an ordinary polyphase rotor. The single magnetic axis effect is, however, in many cases found to predominate, and considerable difficulty may then be experienced in getting the rotor to pass well beyond half-synchronous speed.

8. By the axes of the current sheets are meant the lines along which the current density is zero or the lines with which all the individual current filaments are linked.

Pulling into Synchronism

Of the various torques concerned in accelerating the rotor from rest to synchronism, three, namely the induction motor, the single-magnetic-axis and the eddy current torque, are functions of the speed, and may hence conveniently be referred to as the speed torques. Let us suppose that by the action of the speed and hysteresis torques the rotor has been brought to a speed not far removed from synchronism. Since in the neighborhood of synchronism, the speed torques rapidly decrease with decreasing slip—as shown in Fig. 2—and assume zero values at synchronism, it is evident that these torques would never be able to bring the rotor up to full synchronism; and the hysteresis torque is generally much too weak to effect this. The rotor is finally pulled into synchronism by the varying magnetic reluctance torque, and is maintained at synchronous speed by the same torque, all the other torques vanishing at that speed. As already explained, the varying magnetic reluctance torque may for this reason be conveniently termed the synchronous torque, and we shall in what follows refer to it as such.

We have already seen that the synchronous torque is an alternating torque having a zero mean value for all speeds other than that of synchronism, and is thus incapable of exerting any steady driving or accelerating effect so long as the speed of the rotor is below synchronism. The frequency of the synchronous torque is given by $2\,s\,f$., and the forced oscillations of the rotor to which the synchronous torque gives rise have the same frequency as the torque itself. Now the rotor speed oscillations call into play a further alternating or oscillating torque, owing to the fact that the speed torques change with the speed of the rotor. The speed torques may for small values of the slip be taken to be proportional to the slip, and hence their changes to be proportional to the changes in the speed. The effect is the same as if we were to substitute for the fluctuating speed torques a constant torque equal to the sum of the mean values of the speed torques, together with an oscillating torque whose amplitude is proportional to that of the speed fluctuations.

For the sake of simplicity we shall assume the speed fluctuations to obey the simple harmonic law. They may then be graphically represented in a vector diagram by the projections on the vertical axis of the vector $O\,V$ in Fig. 3, this vector rotating at $s\,f$, revolutions per second. The instantaneous projection of $O\,V$ gives the difference between the instantaneous speed and the mean speed. Since the oscillating component of the speed torques may, as we have seen, in the neighborhood of synchronism be taken to be proportional at every instant to the difference between the instantaneous and the mean speed, and since increase of speed produces decrease of speed torques, it is evident that the oscillating or fluctuating component of the speed torques may be represented by a vector $O\,F$ in direct phase opposition to $O\,V$. Next, if we assume that the

alternating synchronous torque is also a simple harmonic function of the time, then the resultant of the synchronous torque and the oscillating component of the speed torques will give us the alternating torque which gives rise to the periodic accelerations and retardations of the rotor. The phase of this resultant torque is easily determined; for since its zero value must occur at the instant of maximum speed, it is evident that the vector $O\,R$, which represents the resultant torque, must be 90 deg. ahead of $O\,V$, as shown in Fig. 3. Lastly, the synchronous torque vector $O.S$ is obtained by subtracting from the resultant accelerating torque $O\,R$ the oscillating component $O\,F$ of the speed torques. The angular velocity of all the vectors in the diagram of Fig. 3 is directly proportional to the slip, being, in fact, equal to $4\,\pi\,s\,f$.

Let ω denote the excess of the instantaneous rotor speed over the mean speed (corresponding to the vertical projection of $O\,V$ in Fig. 3), and let y stand for the

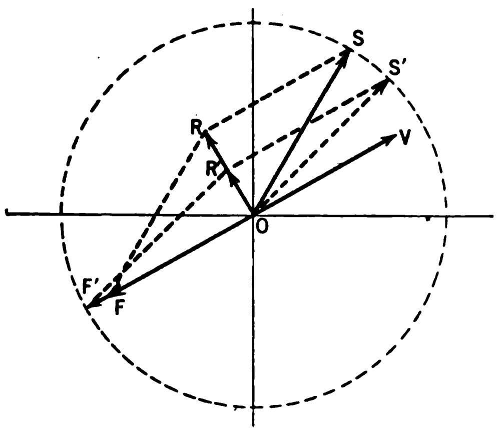

Fig. 3—Vector Diagram of Speed Fluctuations and Torques

instantaneous resultant accelerating torque (vertical projection of $O\,R$). Then, if K is the moment of inertia of the rotor,

$$\text{or} \qquad y = K\,\frac{d\,\omega}{d\,t},$$

$$d\,\omega = 1/K\,y\,d\,t$$

and hence, taking as the origin of time the instant at which ω is zero,

$$\omega = 1/K \int y\,d\,t,$$

from which it is seen that the amplitude of the speed fluctuation $O\,V$ is proportional to the time-integral over a quarter-period of the resultant accelerating torque; or, since the period of this torque varies inversely as the slip, $O\,V$ is proportional to $\dfrac{O\,R}{s}$

By means of the vector diagram of Fig. 3 we can easily show that the amplitude of the speed fluctuations must increase with decreasing rotor slip. For, assuming the diagram to represent the conditions prevailing at a given mean speed, if the mean speed increases, $O\,R$ must decrease; for if it were to remain constant, then owing to the increase of its period due to the decrease of slip, its time-integral over a quarter-period would be increased, and $O\,V$, which is proportional to this time-integral, would increase. This again would cause $O\,F$ ($S\,R$), which is proportional to $O\,V$, to increase; but since the length $O\,S$ is constant, an increase of $S\,R$ could only be brought about by a decrease of $O\,R$ (as shown by the dotted lines $O\,S'$ and $R'\,S'$ in the figure). It follows *a fortiori* that $O\,R$ could not increase with increase of mean speed.

We thus see that as the mean speed of the rotor gradually increases, the vector $O\,V$ undergoes steady elongation, the vector $O\,F = S\,R$ a similar steady elongation ($O\,F$ is proportional to $O\,V$) and the vector $O\,R$ a steady contraction. The vector $O\,S$ remains fixed in magnitude, but gradually approaches $O\,V$. At the same time the angular velocity of all the vectors in the diagram steadily decreases. If we were to consider the actual paths traced out by the extremities of the vectors during the last few cycles preceding synchronism, we should find that V traces out a spiral path opening outwards, F a similar path, R a spiral path contracting inwards, while S continues to move in its original circular path. Just before synchronism is reached, $O\,V$ is moving with extreme slowness and $O\,S$ is only very slightly in advance of it. As $O\,V$, having passed through the horizontal position, moves into the first quadrant, its projection gradually increases until the value of this projection when added to the mean rotor speed gives the speed of synchronism. At this instant all the torques have disappeared with the exception of the synchronous torque.

It is clear that at the instant when synchronism is first reached the synchronous torque cannot be less than the total torque resisting the motion. For, if such were the case, then balance of the total driving and resisting torques must have taken place at some instant preceding synchronism, and such balance would have prevented any further increase of speed, *i. e.*, it would have prevented the rotor from reaching synchronism. Hence at the instant when synchronism is reached, the synchronous torque must either equal or exceed the total resisting torque. In the first case, the rotor will steadily maintain synchronous speed. In the second, further acceleration will take place, and the rotor will settle down to the steady speed of synchronism only after a number of oscillations, the final position which it takes up relatively to the stator poles being such that the synchronous torque arising from the displacement of the magnetic axes of the stator and rotor is exactly equal to the total resisting torque. Whether the rotor comes up to synchronous speed quietly without oscillations, or whether such oscillations take place before it finally settles down to the steady speed of synchronism, the running will correspond to stable conditions. For

in either case a momentary increase of speed results in decrease of driving torque, and a momentary decrease of speed in increase of driving torque. The momentary changes in the driving torque which arise during speed fluctuations, are due partly to changes in the synchronous torque, which tend to check such fluctuations, and partly to the reappearance of the speed and hysteresis torques, which have a similar effect.

Open Versus Closed Field Windings at Starting

The advisability or otherwise of closing the field windings at starting has been repeatedly discussed. The danger of breaking down the insulation by the high voltage induced in the field windings when the stator circuits are first connected to the mains must be taken into account. Although this danger is entirely avoided by short-circuiting the windings before the stator is connected to the mains, there is no doubt that, from the point of view of initial torque and rapidity of starting, it is inadvisable to have the field circuit closed. The effect of closing field windings is similar to that of reducing the resistance of the squirrel-cage or eddy current path,—a procedure which is well-known to lower the initial torque. Again, as the neighborhood of half-synchronism is approached, the powerful single-axis rotor effect may seriously affect the acceleration of the rotor, and may frequently entirely prevent the machine from attaining any speed greatly exceeding that of half-synchronism. In order therefore to increase the acceleration of the rotor during the early stages of the starting process, the field should be kept open; any risk of breaking down the insulation may be guarded against by the use of a suitable field break-up switch.

Now although it is advisable to keep the field circuit open during the initial stages of the starting operation it by no means follows that it would be equally advantageous to keep it open until the machine has been pulled into synchronism. The slip with which the rotor ultimately tends to run under the action of the speed torques will depend on the resistance of the circuits in which the currents giving rise to the speed torques circulate. By lowering this resistance the torque will be momentarily raised and the speed increased. Now closing the field circuit would be equivalent to such reduction of resistance, so that the short-circuiting of the field during the final stages of the starting operation will cause the mean rotor speed to approach more closely to the speed of synchronism than would otherwise be the case. There is thus a distinct advantage in closing the field circuit during the final stages of the starting operation, after the rotor speed has reached a value not differing greatly from synchronism. Cases may in fact arise where a machine with its field open might refuse to pull into synchronism, but could be made to do so by closing the field circuit. This conclusion has been verified experimentally. A certain machine was started with its field open, the rotor potential difference being so low that the rotor settled down to a speed below synchronism, and refused to pull into synchronism. The moment, however, that the field circuit was closed, the rotor locked into synchronism.

Oscillations in Stator Current During the Period Immediately Preceding Synchronism

It is well known that as the speed of synchronism is approached violent fluctuations in the stator current gradually become noticeable. These are indicated in Fig. 5 of Rosenberg's paper, and are easily accounted for. So long as the speed is below synchronism, the field poles are slipping past the stator poles, and periodic fluctuations are taking place in the reluctance accompanied by corresponding fluctuations of reactance which throw the stator current into oscillations. The frequency of these oscillations being $2\,s\,f$ (since the reluctance returns to the same instantaneous value after the pole has moved through a distance equal to the pole-pitch) they are not noticeable at low speeds, and only become apparent when the slip has become sufficiently small.

Some Experimental Results

(*a*) *Relations Connecting Stator Potential Defference with Stator Current, Stator Input and Power-Factor, Rotor Speed and Field E. M. F. when Field is Open-Circuited.* The experiments embodied in the series of curves given below were carried out on a four-pole, five-kw. three-phase converter designed for a continuous current voltage of 100–130 volts at a speed of 750 rev. per min. This machine had laminated main poles, was fitted with commutating poles, but had no special starting devices. While the experiments about to be described were being carried out, the brushes were entirely removed from the commutator. Before each set of readings the machine was allowed to run light for a sufficiently long time to get the bearings into a steady state.

In the first set of experiments, the results of which are exhibited graphically in Figs. 4 and 5, a number of gradually increasing potential differences were applied to the rotor slip rings, and after the speed corresponding to any given potential difference had settled down to a constant value, readings of the speed, current, power, etc., were taken when the potential difference had been raised sufficiently to enable the machine to lock into synchronism, it was still further increased, and then a second series of readings, corresponding to decreasing values of the potential difference was obtained. In the illustrations both the ascending and descending branches of the various curves are given.

Fig. 4 shows the relations connecting speed and field e. m. f. with stator potential difference. Below a potential difference of about 15 volts across the slip rings the machine would not run at all. The speed then gradually increased with the potential difference,

the increase becoming much slower beyond a certain point, and at a slip-ring potential difference of about 45 volts the machine was able to lock into synchronism. During the descending set of readings, synchronism was maintained down to a voltage of about 35 volts. Below this point the speeds obtained with given voltages were found to be uniformly higher than those corresponding to the ascending branch of the curve. Since, as shown by Fig. 5, the power supplied to the machine was found to be lower for decreasing values of the potential difference, in spite of the higher value of the speed, it is to be inferred that for decreasing values of the potential difference the resisting torque was uniformly less. This would indicate a decrease in the frictional resistances, probably due to the temperature of the bearings being higher during the descending set of readings than during the ascending set.

The changes in the field e. m. f. are related to those

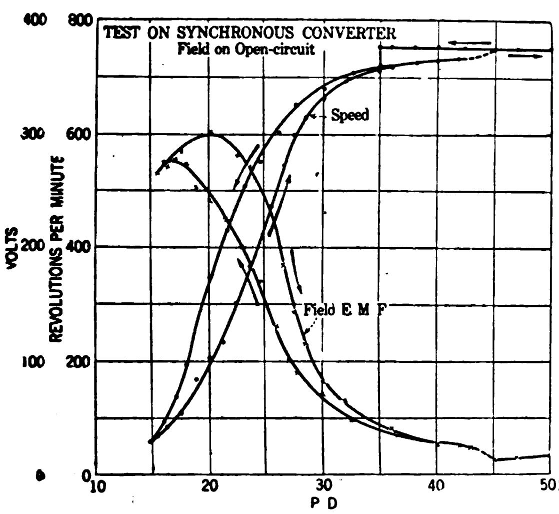

Fig. 4—Curves Connecting Speed and Field E.M.F. with Stator P.D. when Field is Open-Circuited

in the speed. The field e. m. f. may be regarded as proportional to the product of two factors, namely the maximum flux per pole and the slip. At first the field e. m. f. rises with increase of potential difference, indicating that the increase of flux is more important than the decrease of slip. Beyond a certain point the decrease of slip is more important than the increase of flux, and the field e. m. f. begins to decrease. It does not vanish at synchronism, indicating that there is either swaying or pulsation of the flux which enters the main poles. Since for descending values of the potential difference the speed is uniformly higher and hence the slip lower than for ascending values, we should expect the field e. m. f. to be uniformly lower in the former case, and the curve of field e. m. f. shows that such is the case.

Fig. 5 shows the relations connecting stator current, stator power and power-factor with potential difference. The difference between the ascending and descending branches of the power or input curve has already been referred to. It must be remembered that when the machine is not running synchronously, its behavior is similar to that of an induction motor. Hence, owing to the lower resisting torque during the descending set of readings we should expect a smaller current and also a lower power-factor (as is at once evident from consideration of the circle diagram) than during the ascending set; and the curves of Fig. 5 fully confirm this.

(*b*) *Relations Connecting Stator Potential Difference with Speed and Field Current, when the Field Circuit is Closed.* Figs. 6 and 7 give the connection between potential difference and speed when the field circuit is closed through various resistances, and in Fig. 6 the curve corresponding to the field on open-circuit, previously shown in Fig. 4, is repeated for the sake of comparison.

When the field was on dead short-circuit, the machine refused to run up to anything like synchronous

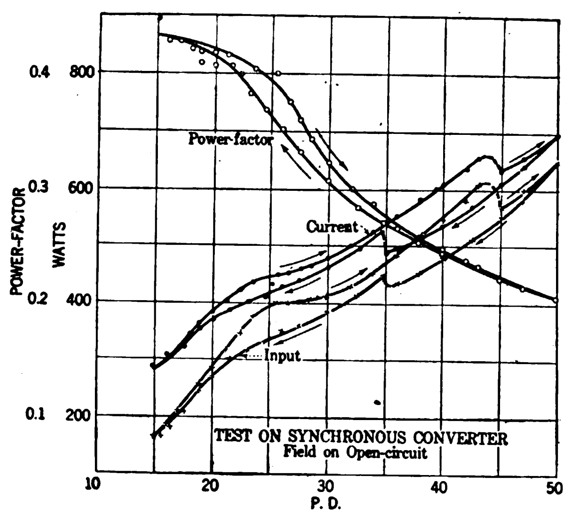

Fig. 5—Curves Connecting Stator Input, Current and Power Factor with Stator P.D. when Field Is Open-Circuited

speed, and seemed to approach asymptotically a speed somewhat above half-synchronism.[9] The explanation of this fact has already been given (reference may be made in this connection to Fig. 2D).

The curves of Fig. 7 show that by the introduction of a suitable amount of resistance into the field circuit the tendency of the machine to settle down to a speed in the neighborhood of half-synchronism may be overcome, and that the machine may be made to lock into synchronism. This result may be explained as follows. Considering the complete torque-speed curve of an induction machine over the entire range of slip, positive and negative, we may regard the point of zero slip as dividing this curve into two branches, one of which corresponds to positive values of the slip, and the other to negative values. If we now suppose resistance to be

9. Incidentally the fact that the machine reached a speed in excess of half-synchronism definitely disposes of the erroneous view previously referred to that the machine tends to lock into exact half-synchronism.

introduced into the rotor circuit, then as is well known, the result is to produce a shearing of the two branches of the torque speed curve in opposite directions from the point of zero slip. Referring now to the torque-speed curves of Fig. 2D, it must be noticed that the point of zero slip for the chain-dotted curve corresponds to half-synchronism, while for the dotted curve the point of zero slip is at full synchronism. From this it follows that the introduction of resistance will in the region between half and full synchronism cause a shearing of the dotted and chain-dotted curves in opposite directions, the dotted curve being sheared from left to right, while the chain-dotted one is sheared from right to left. It is easy to see that this will cause a rise of the minimum in the resultant curve (the full line curve of Fig. 2D), and if the resistance remains sufficiently large the minimum resultant torque will assume a positive value, so that the driving torque will be positive over the

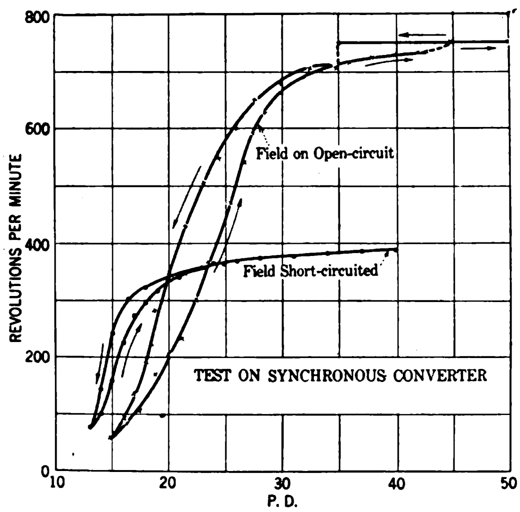

Fig. 6—Curves Connecting Speed with P.D. when Field Is (a) Open Circuited, and (b) Short-Circuited

entire range of speed from zero to synchronism. The shearing of the dotted and chain-dotted curves in opposite directions in the region between half and full synchronism is, however, only one of the causes concerned in suppressing the negative portion of the resultant torque-speed curve, and besides this there is another cause. The dotted curve is the torque-speed curve of an induction motor whose stator is supplied at constant potential difference and frequency; whereas the chain-dotted curve is the curve of an imaginary induction motor whose stator is supplied at variable potential difference and variable frequency, the potential difference being proportional to the frequency. Now the introduction of resistance into the field windings is equivalent to the introduction of resistance into the primary winding of the imaginary motor (since the primary winding of this imaginary motor is represented by the field winding) and is thus equivalent to a reduction of the potential difference across its terminals. This will result in a reduction of all the ordinates of the chain-dotted curve. While therefore, the introduction of resistance into the field circuit results in a simple shearing of the dotted curves from right to left unaccompanied by any change in the values of the ordinates, the effect on the chain-dotted curve is a two-fold one, namely, a shearing from left to right accompanied by a

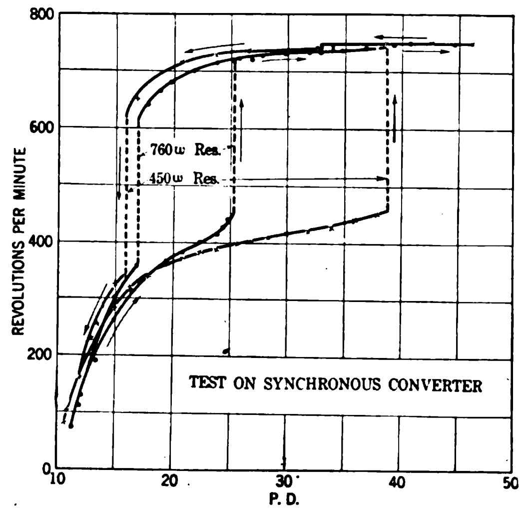

Fig. 7—Curves Connecting Speed with P.D. when Field Is Closed through External Resistance

shrinkage of the ordinates. This shrinkage of the ordinates will further help to suppress the negative portion of the resultant curve.

It will be noticed that in the curves of Fig. 6 which refer to the open-circuit and short-circuit conditions of the field, there are no discontinuities in the speed curves

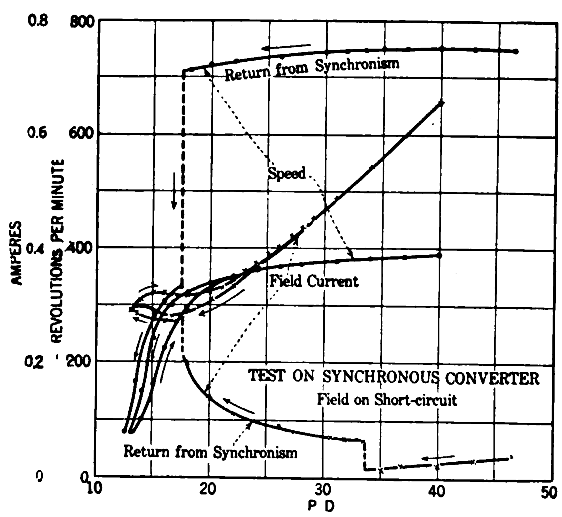

Fig. 8—Curves Connecting Speed and Field Current with P.D. when Field Is Short-Circuited

(except that which occurs at the instant of breaking from synchronism in the case of the open-circuit curve); whereas the curves of Fig. 7 show two well-marked discontinuities (one on each of the curves), in addition to the discontinuities at break from synchronism. These discontinuities are readily accounted for by considering

the shape of the resultant or full-line torque-speed curve of Fig. 2D. In the cases to which Fig. 7 refers the resultant torque-speed curve lies, as already explained, wholly above the axis of speed, all its ordinates being positive; but the curve has two maxima separated by a minimum. It is the existence of this minimum which causes the discontinuities in the speed curves. Stability of running can only be secured by working on a portion of the torque-speed curve which has a downward slope from left to right. With increasing potential difference and speed the point on the (varying) torque-speed curve corresponding to the stable running condition for the given potential difference gets displaced further and further to the right, until finally it reaches the minimum point on the curve. An increase of potential difference beyond the value corresponding to this minimum point results in a passage into the unstable region which lies between the minimum and the second maximum, and no stable running is possible in this region. It is only after the speed has passed beyond the second maximum of the torque-speed curve that stability can again be reached. The point where the discontinuity occurs along the ascending branch gives approximately the speed corresponding to minimum torque; while the discontinuity on the descending branch marks approximately the second maximum of torque. The first maximum of torque would correspond roughly to the lowest speed at which the machine will run.

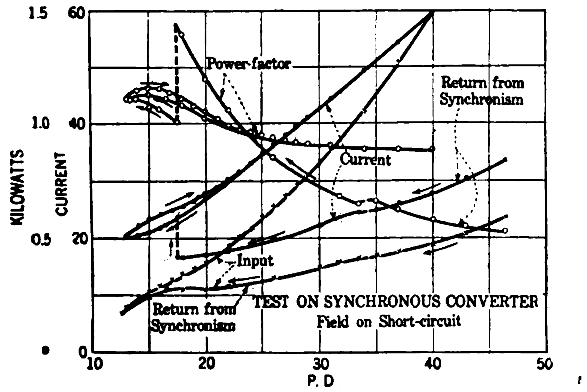

Fig. 9—Curves Connecting Stator Input, Current and Power Factor with P.D. when Field Is Short-Circuited

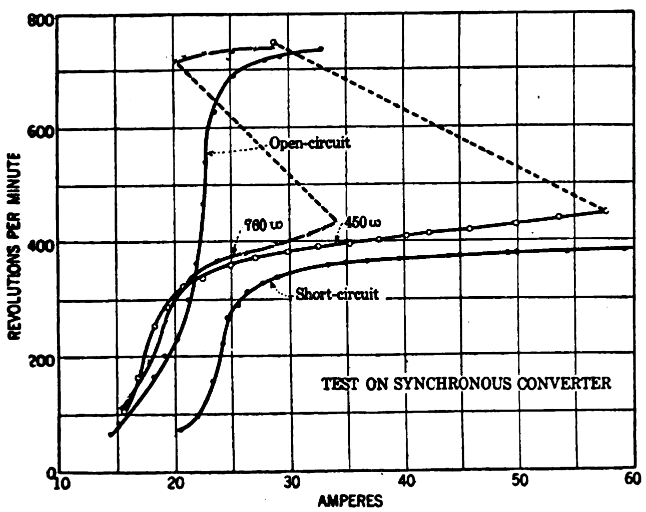

Fig. 10—Curves Connecting Speed with Stator Current under Various Conditions

In Fig. 8 are shown the relations connecting speed and potential difference, and field current and potential difference, with the field on dead short-circuit. Each curve is shown as having three branches. Two of these correspond to the values obtained by first increasing the speed to a certain value and then decreasing it. The third branch, marked "Return from synchronism" was obtained by first open-circuiting the field and raising the potential difference to a value sufficient to enable the machine to lock into synchronism, then short-circuiting the field and taking a set of readings while the potential difference was being decreased. The first two branches of the speed curve are identical with those shown in Fig. 6. The relations connecting current and power factor with potential difference are given by Fig. 9.

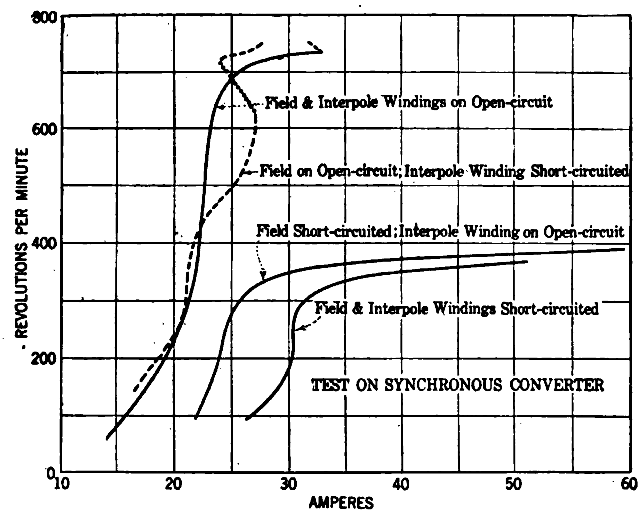

Fig. 11—Curves Connecting Speed with Stator Current under Various Conditions

Returning to Fig. 6, it will be seen that the machine starts with a lower potential difference when the field is short-circuited than when it is on open circuit; and this might at first sight appear to contradict the statement previously made regarding the advantage of starting with the field circuit open. Such, however, is not the case; for the real basis of comparison is not the potential difference applied to the stator, but the *current* taken by it. The relation connecting speed with current for the various arrangements tried is shown in Fig. 10, and it will be seen at once that the machine starts up with a considerably lower current when the field is open-circuited. If the field is closed through a resistance, there will be a certain value of this resistance which gives the best initial results, but even with this

value the current during the intermediate stages rises to a higher value than when the field is open-circuited. On the other hand, it will be noticed that with the field closed through a resistance high enough to allow of the machine being pulled into synchronism, a higher value of speed is reached with a given current than with the field on open circuit.

As the machine experimented on was provided with interpoles, it was thought desirable to try the effect of short-circuiting the interpole winding. In Fig. 11 are given four curves, two of which are for the sake of comparison reproduced from Fig. 10. It will be seen that the worst results are obtained with both main and inter-pole fields short-circuited, and that the short-circuiting of the interpole windings alone does not produce any very marked effect, and is not sufficient to prevent the machine from running up to synchronism.

Summary of Conclusions Reached

1. During the initial stages of the starting period the field should be kept open. If the induced voltage exceeds the limit of safety, a field break-up switch should be provided.

Closing the field circuit not only largely increases the current during the initial stages of the starting period, but may entirely prevent the machine from running up to synchronous speed. This is due to the single-magnetic-axis effect of the field winding.

2. If the field is kept closed and the machine only reaches a speed in the neighborhood of half-synchronism, there is no tendency to lock into exact half-synchronism.

3. There is a distinct advantage in short-circuiting the field after the field has reached a value not differing greatly from synchronism. This will greatly facilitate the final locking into synchronism.

BROADER TRAINING OF ENGINEERS

BY W. I. SLICHTER
Professor of Electrical Engineering, Columbia University

THE report of the Development Committee of the Institute as approved at the Lake Placid Convention, contained a section calling attention to the fact that "engineers do not participate as actively or as prominently in public affairs as they should and that both the public welfare and their own individual advancement would be promoted if this condition could be rectified."

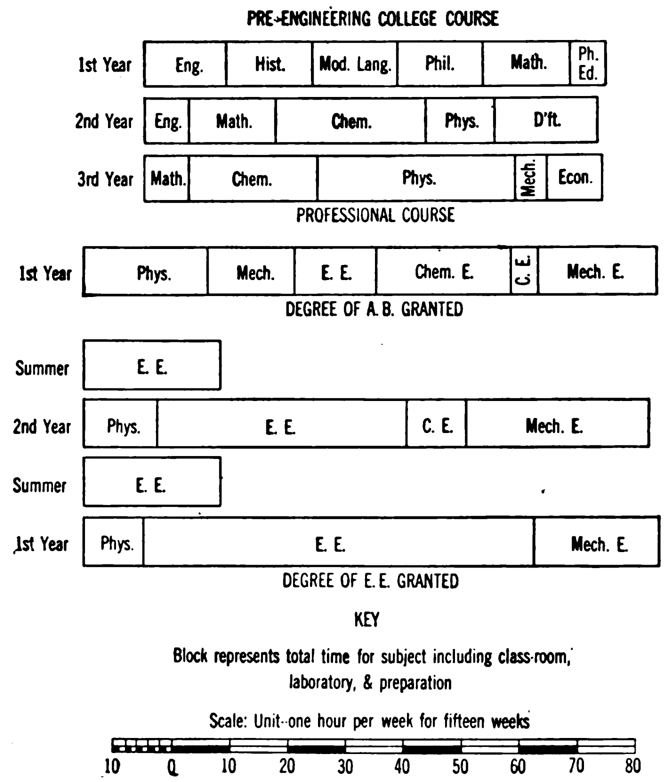
One of the reasons given for this condition was: "too great technical specialization in the engineering curricula of our technical schools and colleges which tend to narrow the vision of the engineering students."

To counteract this tendency it was stated that the Committee would welcome the establishment, at the earliest practicable date of a normal six years' collegiate course in engineering, two years of which at least should be devoted to training in the humane arts and sciences, while the last four should be devoted to a sound training in the sciences and in only the fundamentals of diversified engineering.

Since the Development Committee has called attention to this idea of broadening the training of the engineer, the membership of the Institute should be interested in investigating how such a scheme would work out in practise. To this end there is presented herewith a schematic diagram in a new form, so that he who runs may read, showing the new six year course for engineers which was inaugurated at Columbia University about four years ago. This method of presentation is interesting in itself and was designed to enable the busy Alumnus to grasp at a glance what the institution is doing to the younger engineers.

The diagrams show how the student's time is divided, three years in college and three years in professional work, and the subjects taken each year, weighted in proportion to the time assigned to them.

At the end of the first professional year, the fourth year of residence, the student receives an A. B. degree and here a process of natural selection occurs, the man not suited to engineering work usually decides to take



C. E., Civil Engineering. *Chem.*, Chemistry. *Chem. E.*, Chemical Engineering. *D'ft.*, Drafting. *Econ.*, Economics. *E. E.*, Electrical Engineering. *Eng.*, English. *Hist.*, History. *Math.*, Mathematics. *Mech.*, Mechanics. *Mech. E.*, Mechanical Engineering. *Mod. Lang.*, Modern Language. *Phil.*, Philosophy. *Phys.*, Physics. *Ph. Ed.*, Physical Education.

his sheepskin and go into general business, having had a well-rounded scientific education already. From here on the training becomes more special and at the end of the sixth year the candidate receives the appropriate professional degree, in this case, "Electrical Engineer."

Electric Propulsion on the Steamship Wulsty Castle

BY GEORGE B. PULHAM
Electrical Engineer, S. S. Wulsty Castle

THE Steamship *Wulsty Castle* is at present the only British electrically propelled seagoing ship in commission, and developments are being closely watched by certain prominent British shipping concerns which are keeping the electric ship propulsion proposition steadily in view.

The vessel is designed for a speed of 10 knots per hour, and for cargo carrying only, and is now trading, with other ships of Chamber's Castle Line, between

FIG. 1—THE BRITISH TURBO-ELECTRIC CARGO STEAMER *Wulsty Castle*

southern U. S. A. ports and Europe. She is capable of carrying some 6000 Imperial tons of cargo. Her length between perpendiculars is 356 ft. 3 in. (108.27 m.) beam 48 ft. 9 in. (14.86 m.) and the mean draft when fully loaded is approximately 24 ft. (7.31 m.). In the installation about to be described, two turbo alternators situated one each side of the 30 ft. by 45 ft. (9.14 m. by 13.71 m.), engine room, running in parallel, supply power to two main driving induction motors, which are situated amidships, and which in turn transmit power through double helical single reduction gearing to the single low-speed propeller shaft.

Boilers. Steam is generated in two cylindrical boilers of 13 ft. (3.96 m.) internal diameter by 11 ft. (3.35 m.) long, with 3 in. (76.2 m m.) internal diameter smoke tubes, and designed for a working pressure of 220 lb. per sq. in. The Howden's system of forced draught is used, and Schmidt type smoke tube superheaters are fitted. In addition to the standard marine mountings, "Diamond" tube blowers are installed for keeping the tubes clear.

Originally coal burning, the boilers were recently equipped with the White low pressure oil fuel system. Considerable trouble was caused, especially when burning inferior classes of oil, by heavy soot lodging on the superheater tubes inside the boiler tubes, thus obstructing the draught and materially interfering with the efficient working of the boilers. Keeping these tubes clear necessitated the frequent and liberal use of steam through the Diamond blowers. So serious did this matter become, and to such an extent did it impair the efficient running of the plant, that it was deemed advisable to remove a small percentage of the superheater tubes. This alteration was followed by good results, and by no appreciable drop in steam temperature, which approximately 550 deg. fahr. at the turbine stop valves. A feed heater is installed, through which the feed water returns to the boilers at a temperature of around 223 deg. fahr. A small donkey boiler, designed to work at 100 lb. pressure for driving cargo winches etc. in port is mounted between the two main boilers.

Turbines. In this brief article the writer does not propose to describe the Ljungström turbine[1] in detail,

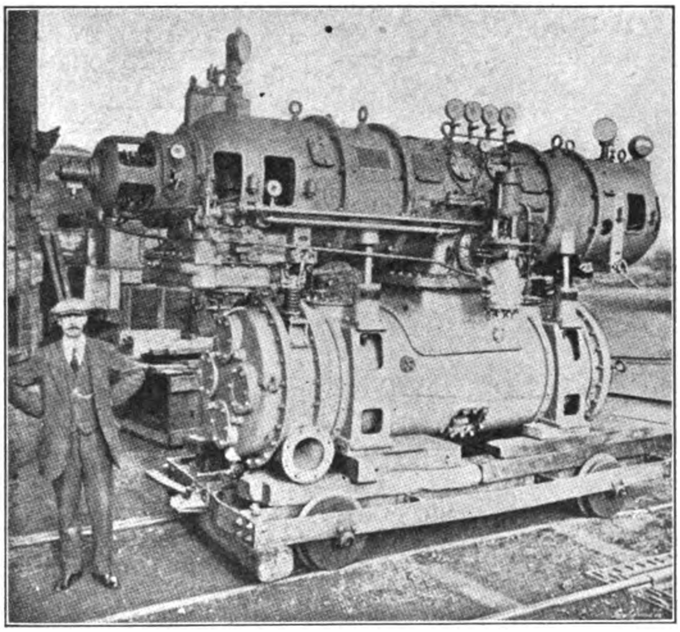


FIG. 2—LJUNGSTROM TURBO-ALTERNATOR AND CONDENSER

and will merely explain that this turbine is a radial-flow machine consisting of two disks carrying concentric intermeshing wings of reaction blading. Steam enters the blading near the center of the disks, and in passing from ring to ring outwards impells one disk in one direction and the other in the opposite direction, each disk being direct connected to an alternator shaft. Fig. 2 shows the port turbo-alternator and condenser of the *Wulsty Castle* leaving the works of the Brush

1. For detailed description of Ljungstrom turbine see *Engineering*, Vols. CV. and CVI, 1918.

Electrical Engineering Company to be placed on board. The exciter can be clearly seen on the extreme left. The condenser is of the "Contraflo" surface type and forms the bed plate of the complete turbo alternator.

A Ljungstrom turbo alternator in the course of erection is shown in Fig. 3. In addition to ventilating the alternator windings, the ventilating fans, one of which can be seen near the slip rings Fig. 3, furnish the air required at the boiler furnaces. After cooling the windings, the heated air is passed along to the Howden's forced draught system where it maintains approximately 9/16 in. of draught at the furnace doors. The main lubricating oil pump and governor gear are both driven by the gear wheel on the extreme right.

these two alternators come into synchronism automatically, an ammeter joined in series with their fields (shown on the right of Fig. 2) indicating when this has occurred. Each of the two three-phase 60-cycle 650-volt, delta-connected main alternators is designed to deliver 625 kw. when running at 3600 revs. per min. The design does not materially differ from standard English practise, the rotors being solid steel forgings with milled slots, which take form-wound coils. Gun-metal wedges hold the coils in place and special caps of the same material secure the end windings from displacement by the heavy centrifugal forces. Provision has been made for exciting one or both alternators from the ship's 20-kw. 60-volt d-c. lighting dynamo,

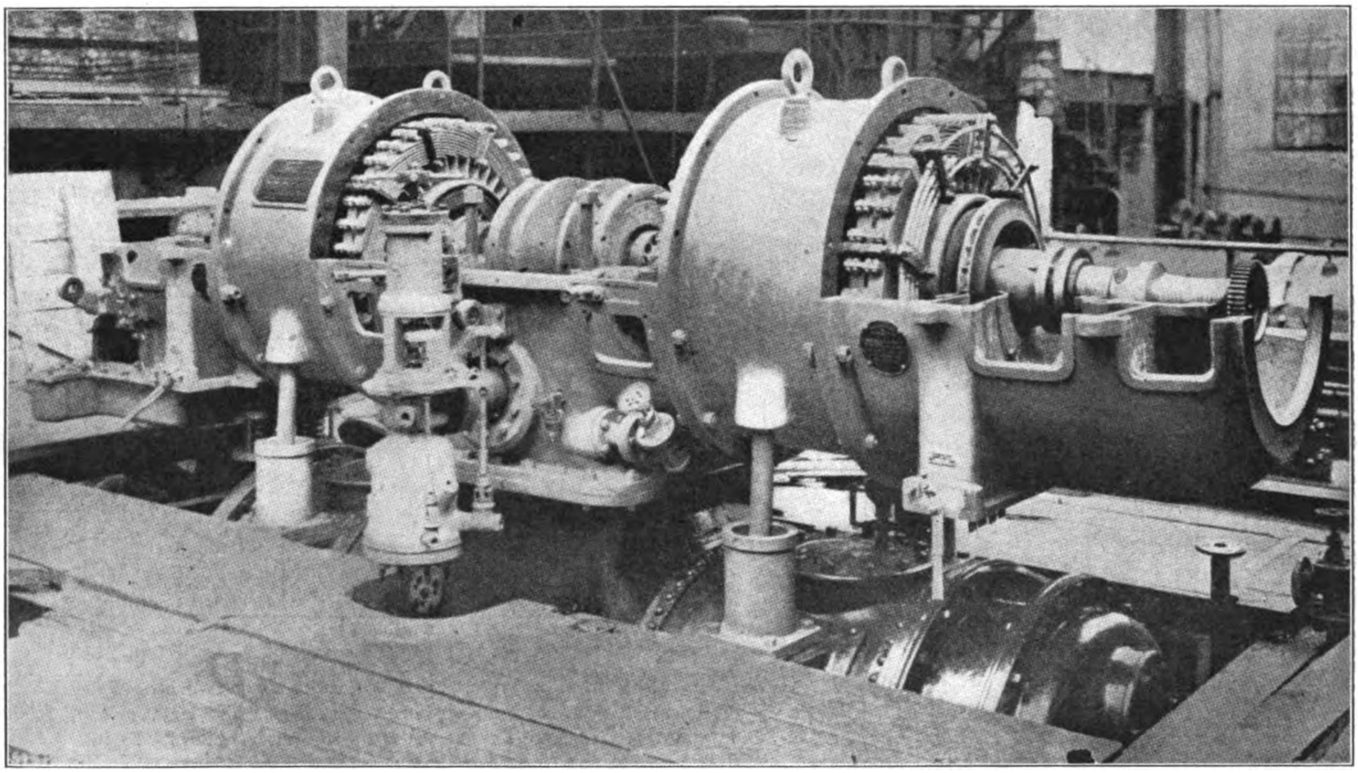

FIG. 3—LJUNGSTROM TURBO ALTERNATOR IN COURSE OF ERECTION

Fig. 4 shows the complete turbine lifted clear of the exhaust casing with the blading intermeshed and clamped in position. The special lifting gear shown allows the turbine to be rotated on one or both of two axes, thus facilitating inspection and handling. Each turbine has 39 rings of which 20 are on one disk and 19 on the other. The external diameter is 28 in. (711 mm.) and the overall length is 17½ in. (440 mm.), the total weight being only four cwt. (448 pounds). The kinetic plant is mounted near the turbo alternator and the three pumps necessary for its operation are mounted on one vertical motor-driven shaft.

Alternators. From the foregoing it will be clearly seen that each turbine runs two separate alternators. These two alternators are permanently connected in parallel, with their fields in series, and are invariably regarded as one unit. As the turbine runs up to speed

should the necessity at any time arise. This dynamo is so arranged that it can be either driven by a motor at sea, or by a small De Laval turbine in port, and is capable of exciting one or both alternators, in addition to meeting the ships lighting requirements and operating the ½-kw. standard Marconi wireless plant.

Main Motors. The two main induction motors are of the wound-rotor type and are fitted with the usual design of brush lifting and short-circuiting gear. Each is designed for a speed of 714 revs. per min. and rated at 785 h.p. Trial tests indicate an efficiency of 95 per cent and a power factor of 0.875 at full load. These motors run in pedestal-type bearings with split spherical bushings. They are arranged for forced lubrication, and each is ventilated by its own fan mounted on the rotor spider. The stator windings are arranged with a single bar per slot and insulated with seamless

mica tube, the end connections being heavy copper strips. The rotor windings are of the cylindrical barrel type as shown in Fig. 5.

Gearing. The gearing is illustrated in Figs. 7 and 8. The pinions are 9.2 in. (233 mm.) in diameter at the pitch line and have 23 teeth. The large wheel with which they gear is 86 in. (2.18 m.) in diameter and the reduction ratio is 9.4 to 1. The total effective width of face is 22 in. (558.8 mm.). The thrust block is of the Mitchell type and is incorporated in the gear case. Two gear-driven oil pumps are mounted at the ends of the pinion shafts, and supply all the bearings including those of the main motors.

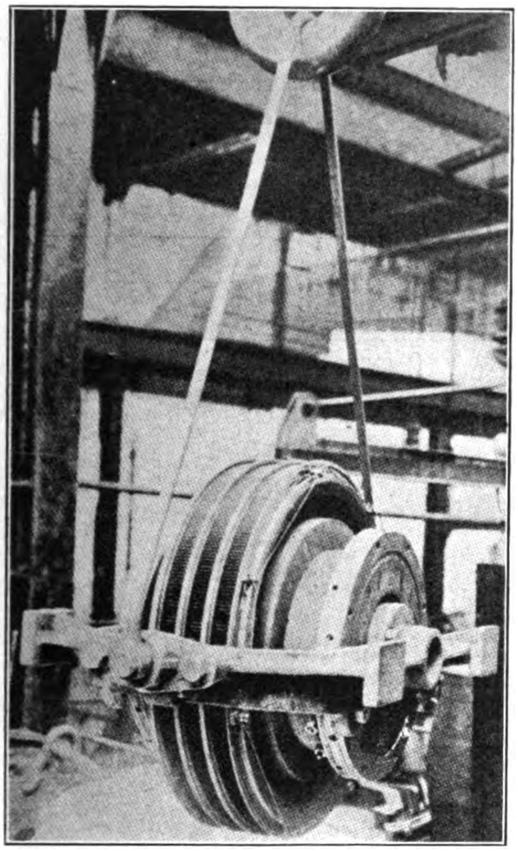

FIG. 4—COMPLETE TURBINE LIFTED CLEAR OF CASING

Switchboard. The switchboard represents standard shore practise. An ammeter, and a hand-operated oil switch, fitted with the usual overload and time-lag arrangements are provided for each alternator and main motor. The wattmeters, exciter voltmeters and field regulators, synchronizing gear, etc. are all of the usual commercial types. The reverse current relay shown in Fig. 10 has been removed.

Control. The turbines are never throttled for the purpose of reducing the speed of the ship. Speed is controlled by manipulating variable resistances in the main motor rotor circuits, a small control hand wheel being used for this purpose.

Reversal is effected by reversing two phases in the main motor stator circuits by means of the control wheel and an automatic reversing oil switch. Orders from the bridge are transmitted by means of the engine room telegraph which is mounted at the control position in the forward end of the engine room. The electrodes used in the main motor rotor circuits are cone-shaped nickel castings, while the electrolyte is a solution of K O H. Two small circulating pumps circulate the electrolyte through specially constructed coolers. The cones are raised or lowered by means of the control wheel, to which they are geared. When the control wheel is in the stop position the tips of the cones are raised clear of the liquid thus breaking the rotor circuits of the main motors. A safety arrangement prevents the closing of the main motor switches until the control wheel is in the stop position, and also prevents the main motors being short-circuited unless the control wheel is in either the full speed ahead, or full speed astern, position.

Operation. Referring to Fig. 10, it will be observed that the first motion of the control wheel from the stop position in either direction closes the reversing switch for ahead or astern running as the case may be. The necessary direct current for operating the automatic reversing switch, it will be seen, is supplied, through a change-over switch, from either exciter. Further motion of the hand wheel (a) cuts out the operating coil of the reversing switch and closes the economy coil circuit (b) lowers the tips of the cones into the electrolyte and starts up the main motors (c) adjusts the shunt regulators of the alternator exciters to meet the changing load conditions (d) locks the main motor switches to prevent them being reclosed should they open with an overload, and finally (e) in the full speed position unlocks the main motor short-circuiting hand lever. The speed then, varies as the angle through which the control wheel has been turned from the stop position, 120 deg. representing full speed. From about 15 revs. per min. any speed can be obtained up to 76, a special locking arrangement enables the control wheel to be clamped in any desired position. A suitably adjusted counterbalance weight allows the control wheel to be turned freely. The time required to reverse the propeller from full speed ahead, to full speed astern or vice versa, is merely the time required to turn the hand wheel from one extreme position to the other, and is approximately 10 seconds. Considerable difficulty was at first experienced in bringing the motors up near enough to synchronous speed, to enable them to be safely short-circuited. To surmount this difficulty, a hand-operated non-inductive grid-type buffer resistance can be placed in parallel and operated in conjunction with the liquid controller when short-circuiting the rotor windings.

Load. In still water the load depends on the draught of the ship, and ranges from approximately 30 per cent when the ship is light to full load value when the ship is fully laden. At sea, the load depends on the position of the propeller in the water, and in bad weather, continually fluctuates from approximately 25 per cent to

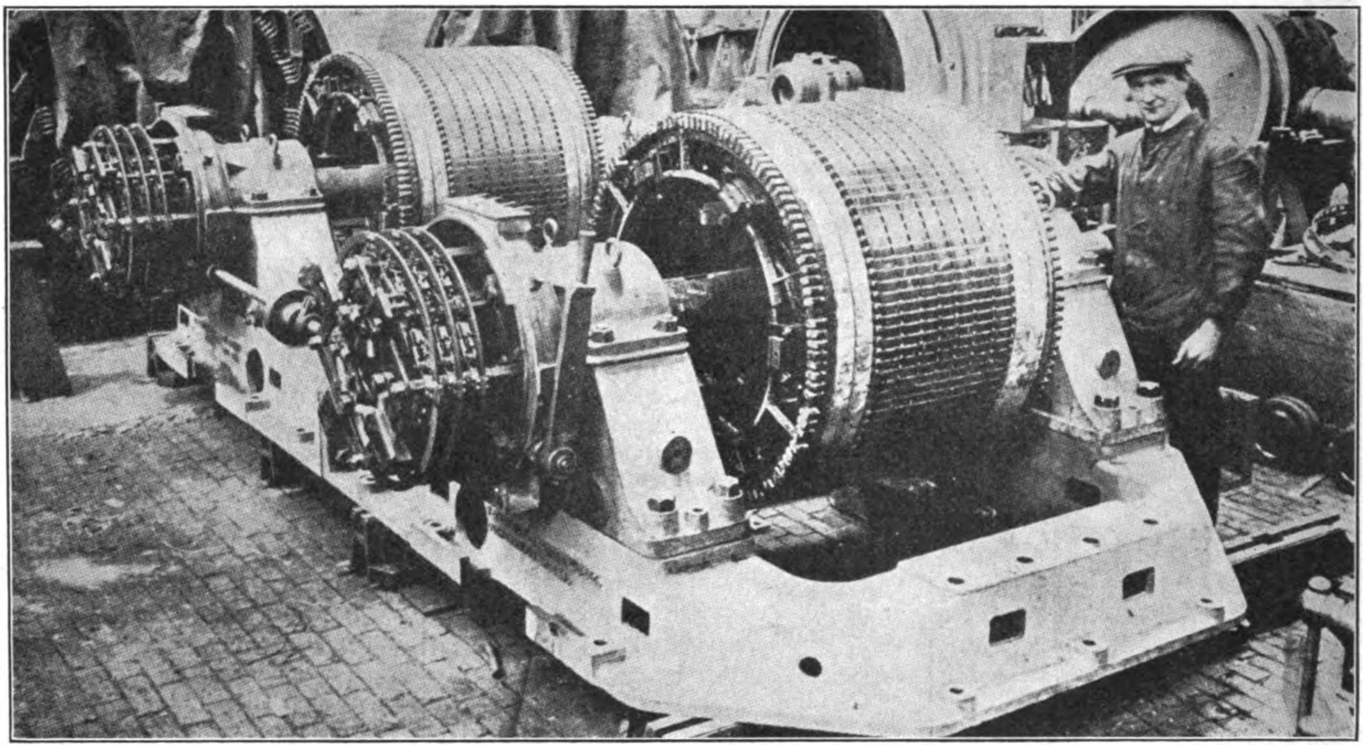

Fig. 5—Rotors of the Main Induction Motors

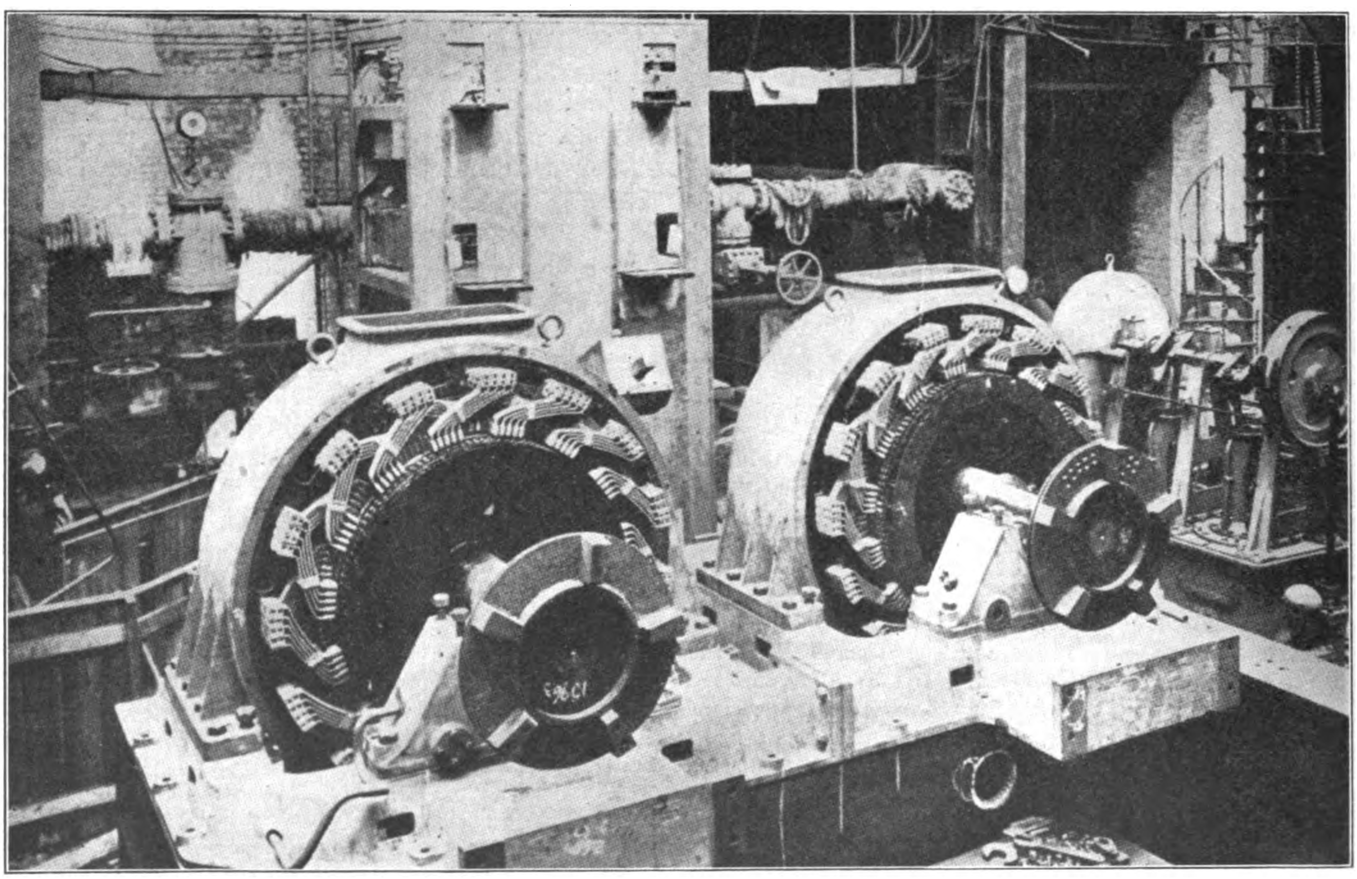

Fig. 6—Main Motors in Course of Erection

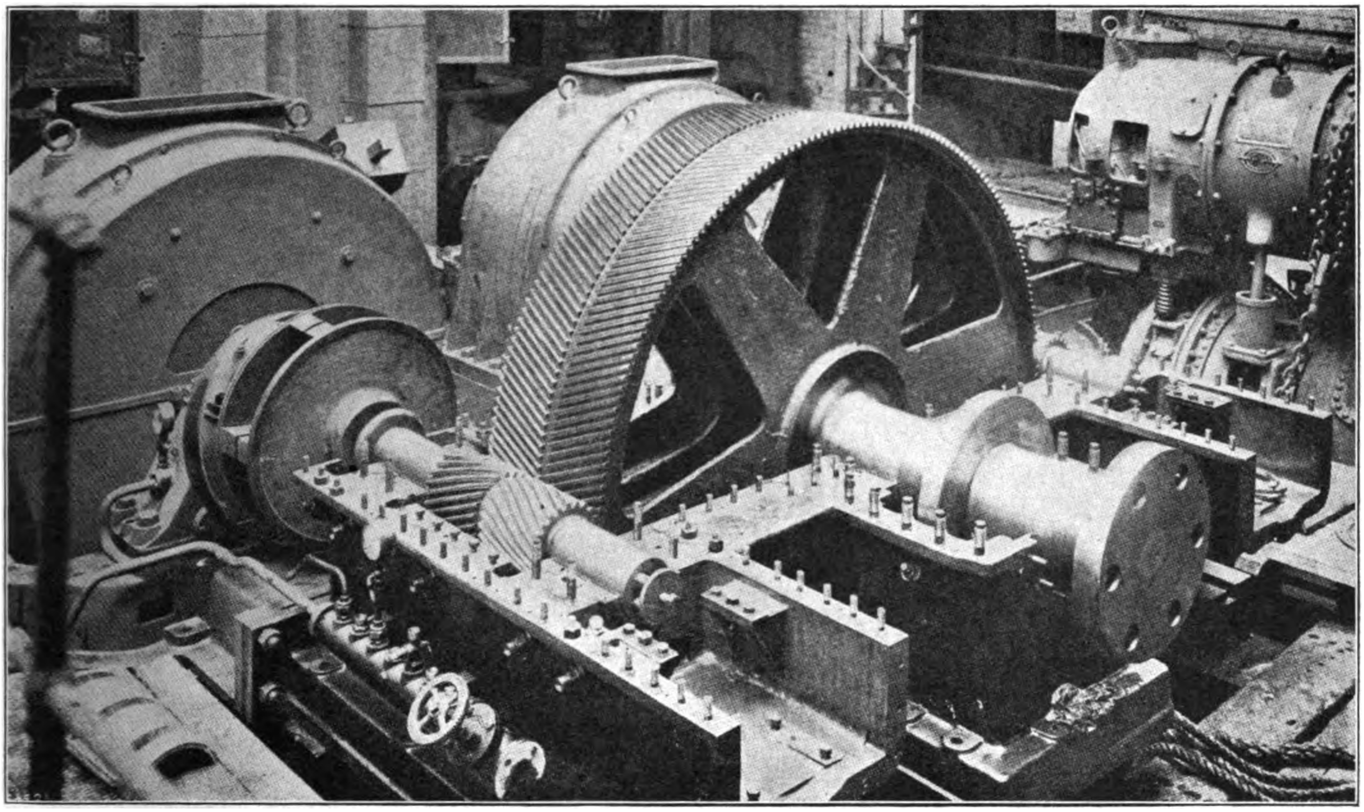

Fig. 7—Gearing with Cover Removed

150 per cent of full load normal value. Even in the heaviest seaway, with this drive, absolutely steady running is at all times assured, and "racing," which imposes very severe strains on other types of marine engines, is here quite unknown.

Auxiliary Motors. Practically all of the auxiliary machinery in this plant is motor-driven, three-phase squirrel cage motors of substantial construction being used. Two small switchboards, for the control of these motors, are mounted on the engineroom after bulkhead. Most of these motors are not equipped with starting devices, and are therefore usually run up with the alternators, in preference to switching them directly across full line voltage. Two 17-h.p. motors drive the main circulating pumps for the condensers at 1730 revs. per min. while two 14-h.p motors operate the combined kinetic, head and pressure pumps at the same speed. The 20-h.p. boiler feed pump motor runs at

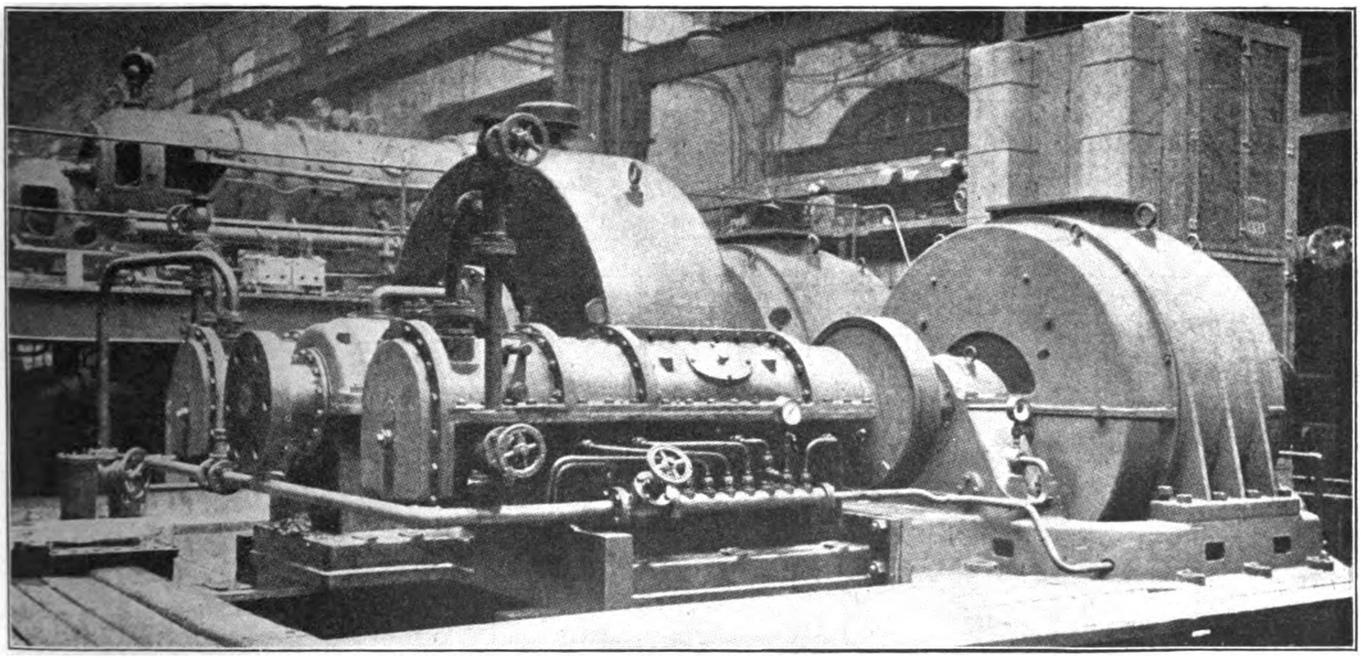

Fig. 8—General View of Main Motors and Gearing

3515 revs. and is equipped with a star-delta starting device.

Two small motors of 1½ h.p. each, circulate the

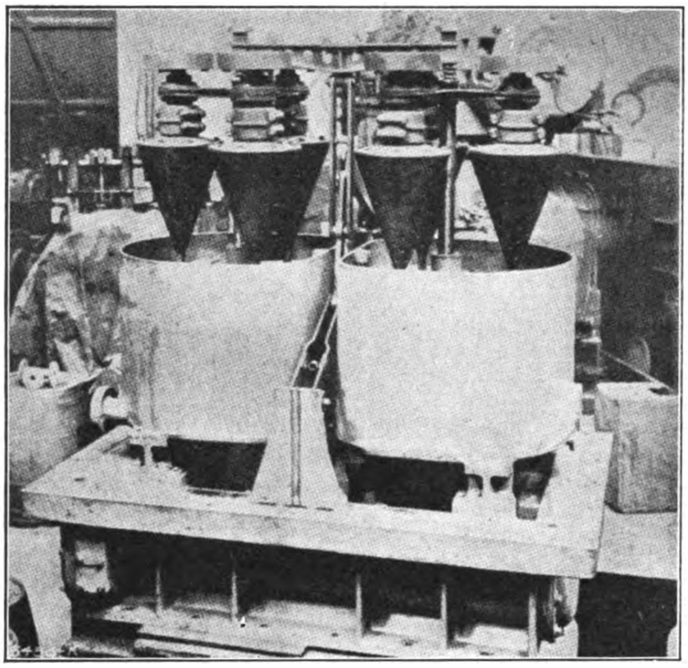

Fig. 9—Variable Liquid Resistance for Controller

electrolyte of the main motor controllers, through coolers of special design, and run at 1100 revs. A 33-h.p. motor, speed 1720 revs. and fitted with an auto-starter, drives the ship's lighting dynamo while at sea, and a 700-rev. per min. 12-h.p. motor, fitted with a star-delta starter operates the ships steering gear. This last motor normally runs light, and is only loaded when the steering wheel on the bridge is moved, this movement being transmitted to the steering compartment by means of telemotor gear. Although the above motors have often been called upon to operate under most unfavorable conditions, they have always furnished excellent continuous service at sea, and have conclusively demonstrated, that for this class of marine work, the squirrel cage motor of reliable make, requiring as it does the minimum of attention, and occupying a very small amount of space,—both important factors in a ship's engineroom—is eminently suitable.

General. Unfortunately no data of a reliable nature are available regarding the economical end, but the writer, judging from previous marine experience with other types of drive, is of the opinion that this is entirely satisfactory. Notwithstanding the severe operating conditions, practically no trouble has been experienced with the electrical end at sea, with the exception of that caused by the deterioration of rubber insulation due to excessive heat while in tropical latitudes. One breakdown, which necessitated the ship being run at reduced speed and efficiency by one alternator while the necessary repair was being affected, was occasioned by a badly sweated alternator rotor slip ring connection generating sufficient heat to loose its solder leaving a loose connection held together by a

Electric Propelling Machinery for U. S. S. Tennessee

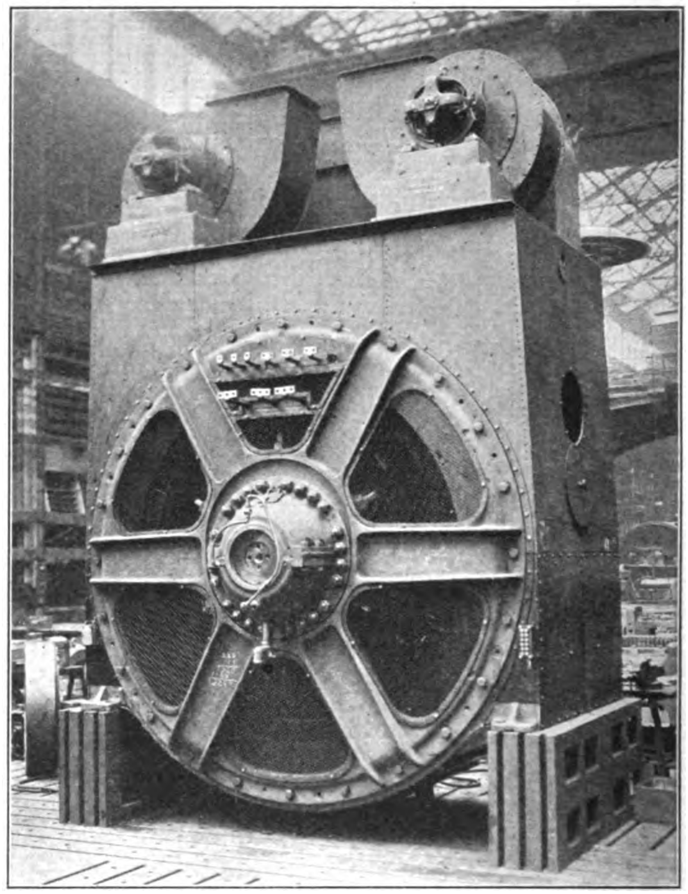
BY WILFRED SYKES

General Engineer, Westinghouse Electric & Mfg. Co.

THE U. S. S. *Tennessee*, which is now rapidly approaching completion, will be the second battleship to be equipped with electric propulsive machinery. The *New Mexico*, which was placed in operation about a year ago, has demonstrated the success of this system of propulsion. The U. S. S. *Tennessee* differs in a number of respects from the U. S. S. *New Mexico*, mainly in connection with the layout of the machinery and the details of the electrical apparatus installed. The *New Mexico* was originally designed for direct-connected turbines and was adapted to electric drive with minor structural changes. Full advantage was not taken, therefore, of the characteristics of electrical drive which allow of the apparatus to be disposed in the most suitable manner. In the case of the U. S. S. *Tennessee* full advantage has been taken of the flexibility in the arrangement of the electrical machinery, and therefore this ship will be the first which will illustrate completely what can be done with electric drive.

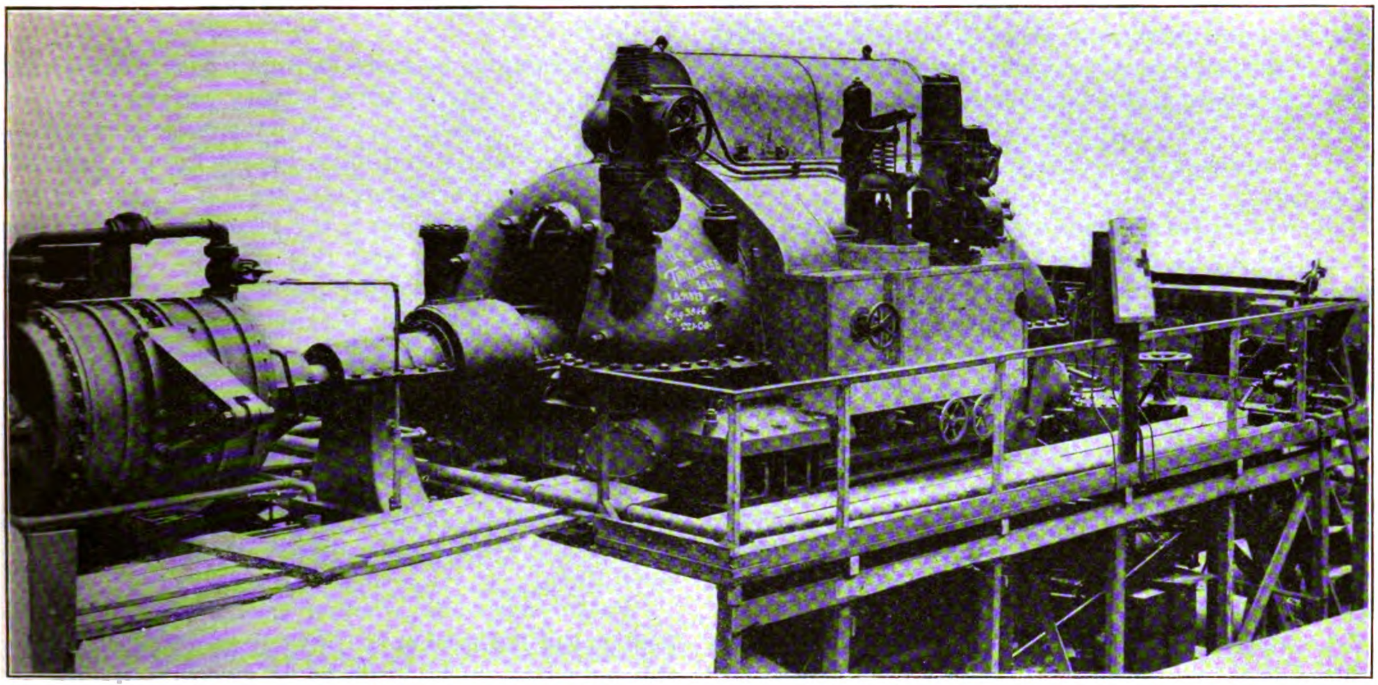
Various claims have been made for electric drive, basing its superiority upon questions of economy, maneuvering capacity and such characteristics. It is believed, however, that the greatest advantage of electric drive for battleships is the ease with which it can be arranged to give the greatest protection to the machinery and the best construction of ship. It can be stated without exaggeration that the use of electric drive would be justified from this standpoint if in other respects it did not compare with what had been previously used, as it is of fundamental importance that the machinery shall be reliable and protected in such a manner as to be as free as possible from injury when in action. The protection given the machinery in the case of the U. S. S. *Tennessee* by means of numerous bulk heads, is very much superior to anything done before in ships of this class, so that it is practically impossible to put the machinery out of operation either by gunfire or by torpedo attack.

The propelling machinery for the U. S. S. *Tennessee* consists of two turbo generators and four propelling motors. The switching apparatus is so arranged that either generator can drive all four motors, or that the two generators in operation each will drive two motors. The motors are grouped in pairs on either side of the ship so as to facilitate maneuvering. The turbo generators have a combined capacity of about 26,500 kw., which will be required to drive the motors when operating under the maximum conditions, each motor then delivering 8375 h.p. The speed of the motors is varied by varying the revolutions of the turbine within certain limits, and the motors also have two sets of poles, so that with the turbine running at full speed there is a speed reduction of about 12 to 1 and 18 to 1 to the propellers. With the motors running at the lower speed only one generator is used, and a speed up to 15 knots is obtained under this condition. As ships of this type operate mainly at speeds of 15 knots or less, the average operating economy is very greatly improved by the possibility of so dividing the power equipment that the best efficiency can be obtained at full speed or about ¾ speed.



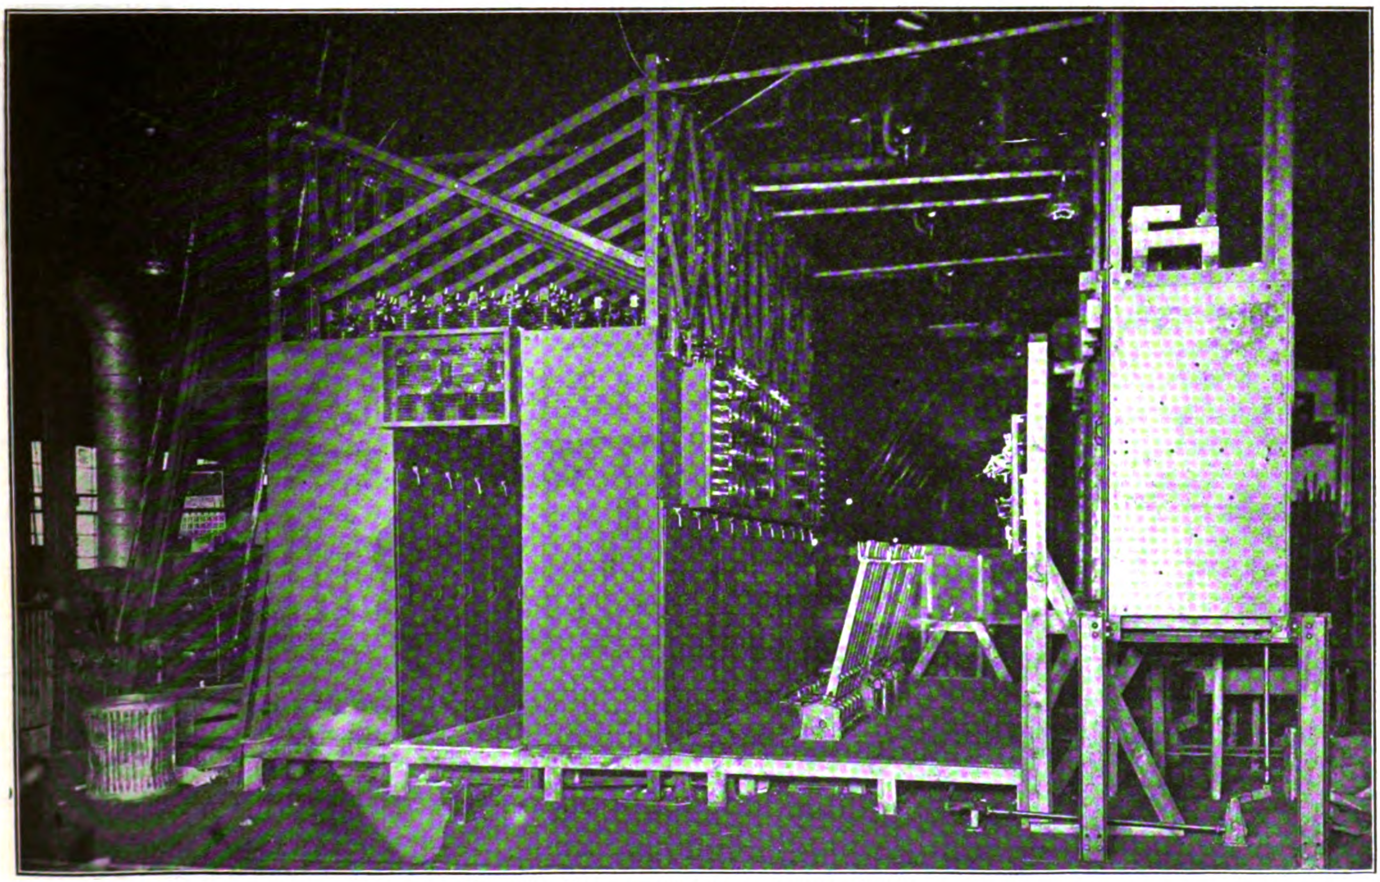
MAIN PROPELLING MOTOR WITH BLOWERS ASSEMBLED IN FACTORY

The turbines are designed to operate with a steam pressure of 250 lb. per sq. in., 50 deg. superheat and with a vacuum of about 28 ½ in. They are of the semi-double-flow type, steam being first expanded in suitable nozzles and flowing through an impulse wheel with two rows of blades. It then expands further through a set of reaction blading until the volume of steam is such as to render it inconvenient to handle, when it is divided and flows through two sets of reaction blading at either end of the turbine. The turbine speed under normal operating conditions is about 2130 rev. per min. maximum, and on test the machine has been run to 2480 rev. per min. The speed of the turbine is varied by means of a specially designed



Main Turbine on Test Floor Coupled to Water Brake

governor which, instead of being loaded by a spring as is usual, is arranged so that the centrifugal weights act against an oil pressure on one side of a piston. With such an arrangement the speed at which the governor will affect the steam supply will vary with the oil pressure, and by varying this pressure, the turbine can be set to run at any speed desired. A specially designed variable pressure valve is provided in the control room, for the purpose of operating the governors, and the only connection between the control room where the speed is varied and the turbine room is an oil pipe connecting to the governor piston.



Control Equipment Assembled in Factory

The generator is a three-phase machine wound for 3400 volts and operates at about 35 cycles at full speed. It is of the usual construction for machines of this size, except that special provisions have been made to avoid salt deposits in the windings. This is a trouble which is likely to occur where machines are operated in salt laden air.

The motors are designed with two sets of poles, being connected for 24 poles for full speed and for 36 poles for cruising. The stator has two separate windings and the rotor has a single winding which is so arranged that it is a polar winding for 24 poles and a short circuit winding for 36 poles. The winding has cross connections arranged in such a manner that they act as equalizer connections for 24-pole connection of the stator, and as short circuiting connections for the 36-pole connection. The motor is started as a wound-rotor machine by means of a liquid rheostat, and in case it is desired to run on 36-pole connection the machine is switched over to this pole connection.

The operation of the ship is controlled by the switching regulating apparatus in the control room. Cables from the generators are brought into this room, passing through the necessary switches to the motors. The secondary leads from the motors are also brought through liquid rheostats which are located in the control room. All necessary instruments for the operation of the equipment and the measurement of the power are located in this room, and the necessary telegraphs and other communicating devices are suitably located so as to facilitate communication with the navigating officers. All switching is done by means of oil immersed switches, and while normally circuits will be broken with the field of the generator disconnected, the switches are of such construction that they can be operated under full power. The variable pressure valves for operating the turbine governors are located in this room, as well as the rheostats for varying the field of generators.

The field of generators is controlled through a machine which is arranged to buck or boost the 240-volt direct-current power circuit of the ship. This booster is motor driven and the exciting voltage is varied through the booster field which is reversible.

The guarantees for this ship based on 250 lb. steam pressure, 60 deg. circulating water with no superheat are as follows:

21 knots	....	11.9 lb.
19 "	....	11.65 "
15 "	....	12.1 "
10 "	....	15.45 "

These figures include all the power required for driving the circulating pumps, condensate pumps, ventilating blowers for machines and excitation.

PRODUCE AND SAVE

It is coming to be more and more widely recognized that the only effective remedy for the abnormal economic conditions which have resulted in successively higher prices and higher wages lies in increasing production and increasing savings. Produce all you can and save all you can is the solution of the present economic difficulties, and this thought is admirably expressed in the following paragraphs by Albert W. Atwood in the *Saturday Evening Post:*

"The only way to break the vicious circle is by the slow, painful process of work and save throughout the world. In time, Europe will be able to supply her own needs. In time, the supply of goods will catch up with demand, and then we shall have gradual deflation in place of inflation, because it will be possible slowly to pay off the world's debts and the bank credits based upon them.

"Patent nostrums, whether they apply to business men on the one hand or to the wage earner on the other, will only lead up blind alleys. Improved machinery, more scientific devices, better organization of industry, more economic distribution of its products, better training of the worker, more democracy in industry and more good will between capital and labor—all these will help. But they take years, generations perhaps, to bring about, and patent schemes to rush them into being are pitifully futile.

"And as for working and saving, the bitter truth is that this doctrine will prove our salvation only if people learn that it applies to themselves as well as to the other fellow."

PLANS FOR DISABLED SOLDIERS

It is announced that the War Department, Federal Board for Vocational Education, and Civil Service Commission will within a few weeks have completed a plan they have had under consideration for some time, one of cooperation whereby the employment under the War Department of partially disabled soldiers, including those who ordinarily would be barred from civil positions because of their physical condition, will be facilitated in every way possible, and which will permit the employment of partially disabled men on same basis as those who have not sustained physical injury. War Department has considerably more than 100,000 civilian employees in its various establishments, and it is believed by Government officials that this large force can absorb several thousand partially disabled men without serious detriment to the service.

The Expression of Dielectric Losses in Cables

BY WM. A. DEL MAR

Chief Engineer, Habirshaw Electric Cable Co.

Dielectric losses in cables depend upon the characteristics of the current, the dimensions of the cable and the specific qualities of the insulation. In order to compare the specific qualities of different insulations with respect to dielectric losses, it is desirable to find a method of expressing these specific qualities independently of current characteristics and cable dimensions. This will permit different insulations to be compared even when tests are made at different voltages, or on cables of different sizes. A method of attaining this result is here suggested.

The method consists in expressing the specific quality of the insulation with respect to dielectric losses, in terms of the product of its power-factor and specific inductive capacity. This may be termed the coefficient of dielectric loss and is hereinafter designated by the letter K_L.

If the specific inductive capacity or specific capacitance may be considered to have a maximum value of 3.5 for impregnated paper insulation, the coefficient of dielectric loss must be between zero and 3.5, the value zero corresponding to zero power factor or perfect insulation, and the value 3.5, to unity power factor or the worst insulation. Hence the lower the value of K_L, the better the insulation from the point of view of dielectric losses. The following values are characteristic of different makes of insulation.

VALUES OF K_L

Temperature deg. cent.	Cable No.					
	I	II	III	IV	V	VI
50	0.093	0.12	0.30	0.22	0.31	0.31
70	0.32	0.43	0.55	0.65	0.78	0.90
90	0.67	0.89	1.57	1.59	1.68	1.80
110	1.13	1.51	2.98	2.93	2.96	2.93

It is proposed for specification purposes, that the Institute standard maximum temperature be adopted, and that, unless otherwise stated, K_L shall refer to that temperature, which is given as 85 deg. cent. for paper in the 1918 Standardization Rules.[1]

The coefficient of dielectric loss may be derived as follows from single-phase measurements of dielectric loss on a triplex cable.

Fig. 1 shows a diagrammatic representation of the capacities in a triplex cable.

Let I = charging current in line, per mile of cable

I_c = charging current per mile from one conductor to *each* other conductor

I_s = charging current per mile from each conductor to sheath

E = kilovolts between conductors

C_c = microfarads per mile one conductor to another

C_s = microfarads per mile one conductor to sheath

Then $I = \sqrt{3}\, I_c + I_0$

$I_c = 2\,\pi f E\, C_c$ in milli-amperes

$I_s = 2\,\pi f\ E/3\ C_s$ in milli-amperes

$$I = 2\,\pi\,\sqrt{3} f E\,(C_c + C_s/3) \qquad (1)$$

Let w = dielectric loss, watts per mile of cable

θ = power factor angle

Then

$$w = \sqrt{3}\, E\, I \cos\theta \qquad (2)$$

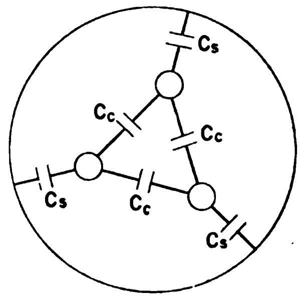


Fig. 1

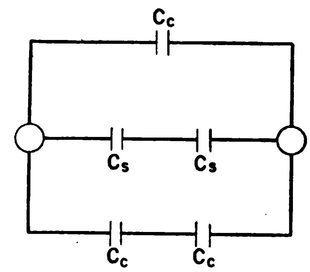

Fig. 2

Combining equations **1** and **2**

$$w = 2\,\pi f E^2 \cos\theta\,(3\,C_c + C_s) \qquad (3)$$

Now C_c and C_s are purely mathematical conceptions not susceptible of direct measurement. They are the capacities of imaginary condensers. The real capacities differ due to being composed of groups of these imaginary capacities in series or parallel. We must therefore reduce these imaginary capacities to real capacities.

Let C_1 = actual capacity (as measured) between any two conductors, the third being insulated.

Then C_1 is composed of the combination of C_s and C_c shown in Fig. 2.

$$C_1 = 1\tfrac{1}{2}\,C_c + \tfrac{1}{2}\,C_s$$

$$= \tfrac{1}{2}\,(3\,C_c + C_s)$$

or

$$(3\,C_c + C_s) = 2\,C_1 \qquad (4)$$

Combining equations (3) and (4)

$$w = 4\,\pi f E^2 \cos\theta \,.\, C_1 \qquad (5)$$

Let k = specific capacitance

and $C = C_1/k$

Then

$$w = 4\,\pi f E^2 \cos\theta \,.\, k \,.\, C$$

Let $K_L = k\cos\theta$

Then,

$$w = 4\,\pi f E^2 K_L\, C \qquad (6)$$

1. Rule 677 of the 1918 Standardization Rules says that the maximum safe temperature, in degrees cent., at the surface of the conductor shall be 85—E, where E represents the r. m. s. operating e. m. f. in kilovolts between conductors. It is proposed to make 85 deg. cent. the temperature of reference whatever the voltage of the cable.

Let W = watts lost per foot of cable
Then

$$W = \frac{4\pi}{5280} f E^2 K_L C$$

$$= 0.00238 f E^2 K_L C \qquad (7)$$

$$\text{or } K_L = \frac{420\, w}{f E^2 C} \qquad (8)$$

The coefficient C, depending only upon the size and shape of conductor and upon the thickness of insulation may be derived either from a general table such as Table II or calculated from a formula such as the one which follows:

$$C = \frac{0.01945}{A} \qquad (9)$$

Then $i = \sqrt{3}\, i_c + i_s$

$$i_c = E/R_c$$

$$i_s = \frac{E}{\sqrt{3}\, R_s}$$

$$\text{Therefore } i = E/\sqrt{3}\,(3/R_c + i/R_s) \qquad (10)$$

These resistances are purely imaginary conceptions. Let R be the actual resistance from one conductor to another, the other conductor and sheath not being in circuit. All resistances are expressed in ohm-miles.

Then

$$R = \frac{2}{(3/R_c + 1/R_s)}$$

$$\text{or } (3/R_c + 1/R_s) = 2/R$$

$$\therefore i = 2/\sqrt{3} \times E/R$$

TABLE II

$$\text{where } A = \log_{10}\left[\frac{d}{a}\;\frac{b^2 - d^2}{\sqrt{b^4 + b^2 d^2 + d^4}}\right]$$

in which a = radius of conductor, cm.
b = inside radius of sheath, cm.
d = distance between centers of conductors.

The above calculations are based upon the assumption that the ohmic losses are so low that it is not necessary to take into account the fact that they are independent of the frequency.

This may be easily shown.

Let i = amperes per mile of leakage current, per conductor
i_c = amperes per mile of leakage current from one conductor to another
i_s = amperes per mile of leakage current from one conductor to sheath
R_c = ohms per mile resistance, one conductor to another
R_s = ohms per mile resistance, one conductor to sheath

Let W_0 = watts lost in length having resistance R

$$= \sqrt{3}\, E \,.\, i\,.$$

$$= \frac{2\sqrt{3}}{\sqrt{3}}\,\frac{E^2}{R}$$

$$= 2\, E^2/R \qquad (11)$$

If E = kilovolts between conductors
R = megohm-miles
W = watts per foot, ohmic loss

$$W = \frac{2}{5280}\,\frac{E^2 \times 10^6}{R \times 10^6}$$

$$= \frac{1}{2640}\,\frac{E^2}{R} \qquad (12)$$

Suppose R = 10 and
E = 12

$W = \dfrac{10}{2640}$ = 0.0038 which is negligible in comparison with the loss due to the capacity current.

Pure Science and Industrial Research

BY J. J. CARTY
Vice-President, American Telephone & Telegraph Co.

IN MY address before the A. I. E. E. in 1916, to which Dr. Bumstead very kindly referred, I laid stress upon the importance of research conducted solely for the advancement of science. I testified to the great debt which applied scientists owed to the pure scientists, and I suggested that the industries owed an immense debt to science which they should pay by liberal contribution to those scientists, who, conducting experiments solely for the increase of knowledge, and without any expectation of pecuniary gain, give their services to this work. That paper was very well received, and I have been very much gratified to see how much good it has done to workers in pure science and among the physicists, particularly in gaining them recognition, for it appears that, as representing the American Institute of Electrical Engineers I had said something from the practical side which, if said by the theoretical or academic scientists, would not have had so much weight.

The address which has been referred to seemed to express the views of the National Research Council so well that it was published by that body as its first tract, and has had a wide circulation in this country, and abroad. The views which were set forth in the address have been very generally accepted, and to those who want to follow up this important line of thought, I suggest that they read that paper, if they have not done so; if they have done so, they might read it again, in the light of what I may have to say this evening.

The movement for research, particularly in the matter of pure science, has received a great impetus in this country. The National Research Council has been formed, and it has for its object the encouragement not only research in pure science, but also research in industrial science. As a result of its activities, there was a meeting called in London by The Royal Society which I attended as a delegate from the National Academy, at which the foundations were laid for an international research council.

At this meeting there were represented members from the Academy at Rome, the Royal Academy of Serbia, the Brussels Scientists, those from the French Academy, those from the Royal Society of England, and those from Brazil, in fact, representatives of all the Allies were present. These gentlemen were constituted the charter members of an International Research Council which later met at the rooms of the French Academy in France. All of this was an outgrowth of the war. The war brought the pure scientists and the applied scientists to the front. The work which they did in the laboratory and on the field of battle is a matter of history. It is work in which the members of both of our societies participated to a high degree.

Doctor Bumstead has very kindly referred to my testimony concerning the debt which applied science owes to pure science, and he has, in return, very generously acknowledged the debt which the pure scientists owe to the applied scientists. Now we are coming to a third situation, where we must consider the debt which civilization, as a whole, owes to science, both pure and applied, and the obligations which pure science and applied science assumes, and has assumed, to the public. Those who are engaged in work such as ours have undertaken immense obligations in behalf of the public, not fully realized by us, and very dimly perceived by the public.

The pure scientist furnishes to the engineer the raw material for his work. That is well illustrated, I think, in the telephone art. That art is founded primarily upon the work of the pure scientist and specifically upon the work of the physicist. When the telephone was invented, it was thought by studying the structure and operation of the human ear from the standpoint of the physiologist that we might find the solution of many problems in telephony, but a brief study showed that the answer was not to be found in that direction. We then turned our minds to the physicists, and at the very beginning our first advice and help came from the professors of physics in the universities. One of them, Prof. Cross was one of the very first advisers we had, and I am glad to say that he is still able to give us good advice.

When we consider the progress of the art of telephony, we will see that in the beginning it was difficult to speak even for a few miles. The charges for the telephone were considered to be excessive—they were so large that very few people could make use of it—but by following the pathways outlined by the pure scientist, studying his discoveries, and by the aid of the applied scientist, the improvement that has been made has been most remarkable.

During that period of forty years, you will find that wages, the cost of materials, and of living, were going up and up and up in an ascending curve. All of the fundamental factors which make the cost of telephony have been increasing. Wages have gone up, the hours of work have been lessened, the amount of air space per cubic foot allowed for employe has been increased, medical attendance has been provided, welfare work of all kinds has been arranged for, and in every way the comfort and health of the employe has been benefited—All these factors make for increased costs, but, notwithstanding all that, if you will look at the curve of the prices charged for telephone service you will find that they have been going down and down.

Abstract of an address before a joint meeting of the A. I. E. E. and the Am. Phys. Soc., Philadelphia, October 10, 1919.

Why is that? It has not been taken out of the inexhaustible treasury of the capitalists, because there is no such thing. Where has this come from. It has not been squeezed out of the flesh and blood of human beings. It has come from a more intelligent utilization of nature's forces—it has been squeezed out of old Dame Nature herself.

Now, there lies, I think, the great future for our organizations—the American Physical Society representing the pure scientist and the American Institute of Electrical Engineers, representing the applied scientist, —our great duty is to join hands in the conquest of the forces of nature.

We must realize that nature's resources are not limited to a fixed amount, so that if one gets something he must take it away from somebody else, but that outside of the boundaries of our present knowledge there is an unlimited store, and that we, instead of being engaged in a struggle of taking one from the other, should all be engaged in a struggle where we will all be working shoulder to shoulder in the struggle against the forces of Nature. We should believe that lying outside of the boundaries of our present knowledge, away off in the infinite, is a store of resources which it is your business, gentlemen, the pure scientists and applied scientists to discover and to mould into useful form for mankind.

I have spoken of the debt of the applied scientist to the pure scientist, and the debt of the pure scientist to the applied scientist. I now wish to say that both together, owe a debt to the public, and that both the pure and applied scientists have an obligation to the public to push forward the frontiers of our knowledge and occupy the newly discovered territory and to work all materials which are found therein for the benefit of mankind.

At present we are engaged in a very difficult situation growing out of the war. We have had many interferences with natural economic laws. Some were necessary and some unnecessary. The result is that we got into a sort of orgy of rising wages, in turn followed by increased prices, which, when the circle is complete, brings the workman right back where he was before, and the only remedy is to start off with another increase of wages, and that increase of wages followed inevitably by an increase in the price of commodities and the cost of living, and we are right back where we started. We are in a vicious circle. The conference at Washington is dealing with that vicious circle. All they can hope to do is to slow down the rate at which we are chasing ourselves around in that circle.

But we as scientists and engineers have another duty. It is our business to break through that circle, and I say, gentlemen, the only way out of this vicious economic circle is to send out the pure scientist to break through it, and to follow him up by the applied scientist. Once that idea gets into the public mind, once it gets solidly into our own minds, then we will look on our scientific work as an occupation of the highest kind, in which a man could engage.

I believe when the railroads are returned to their owners and affairs become more stabilized in this country, that we will have in connection with every great railroad, an important industrial research laboratory. All the great manufacturers, and all the manufacturers' associations realize the importance of industrial research, and are going to the colleges for men to conduct the laboratories. It is our business to educate the large industries to the fact that they must help to support the pure scientist; that they must regard him as though he were a discoverer of new mines which may contain vast riches for them, and that unless the pure scientist continues his discoveries, all fundamental progress will cease. Therefore, I think we must encourage corporations of all kinds, and individuals to contribute to the work of pure science, and justify it on the ground that it is a proper use of the funds of the corporation.

As time goes on, speaking in terms of the life of a nation rather than the life of a man, I believe that through the work of such societies as ours, that through the scientific discoveries which their members will make and apply, the working man, even the humblest, will enjoy comforts and advantages that are now undreamed of. These matters I am now discussing relate largely to material things and do not purport to solve those ultimate problems which are dealt with by philosophy and religion. While we cannot promise happiness to man, nevertheless I have faith that your scientific work, carried on for one hundred or two hundred years, or perhaps more, (a short time in the life of a nation) will place at the disposal of men such great material advantages that even the humblest will have the leisure and education and equipment to consider, as a man and not as a beast of burden, those higher problems of life and happiness which comprehend more than material things.

DECREASING TIMBER SUPPLY

The Forester of the Department of Agriculture states in Annual Report that the rate of depletion of forests of this country is more than twice, probably three times, what is actually being produced by growth in form serviceable for products other than firewood. Consequently, high prices of lumber are not wholly due to increased costs of production. An important factor is the ever-retreating sources of timber supply. Already the supplies of all the great eastern centers of production are approaching exhaustion, with exception of the South, and even there most of the mills have not over 10 to 15 years' supply of virgin timber. Already the southern pine is being withdrawn from many points as a competitive factor and its place taken by western timbers. This inevitably results in added freight charges, which the consumer must pay.

THE TECHNICAL STORY OF THE SYNCHRONOUS CONVERTER

[*Continued from page 26*]

It should be added also, that when the Westinghouse engineers added copper dampers to their laminated poles and thus stopped hunting, they discovered that difference in wave form was not controlling, in any sense, and they saw why the first General Electric converters, with their solid poles, apparently had hunted less than the Westinghouse, due to the damping currents in the poles themselves.

Of course, after the hunting trouble on 25-cycle converters had been practically eliminated by the dampers, there was no real necessity for following the "induction" type further, and that work was abandoned, except in one or two special instances. In 1894, the company had undertaken to build a 10-h. p., 60-cycle converter, which, however, did not prove at all successful in service, due to hunting. It was brought back to the shop for further investigation and experiment and it was determined that it would operate without any hunting whatever, with its field coils short-circuited on themselves, thus forming an induction converter. A new field was then constructed with very short poles and without any field winding and with a very small airgap, about the same as that of a small induction motor. This, at first, did not work as well as with the former field with the field coils short circuiting themselves. It was then assumed that the short circuited field coils must have had something to do with the operation and therefore on the new field, with small airgap, a heavy copper one-turn field winding was placed, short circuited on itself. With this winding, the operation was again quite satisfactory, and this machine was used for experimental purposes for many years. Its power factor was not as good as the excited-field type machine and the direct current delivered by it was slightly pulsating, so much so that it showed as a flicker on arc lamps when used for motion picture work.

Another type of "induction" converter was experimented with, about this time. In 1894 and 1895, the Westinghouse company, in putting up its new shops at East Pittsburgh, had adopted 25-cycles, two-phase for its power system. A number of converters of 125 and 250 volts were designed and built for delivering direct current for the testing rooms. These converters operated fairly well except that they hunted at times, the copper damper not yet being devised. This hunting led the writer to consider the use of one of these converters as a synchronous running machine without any field winding whatever. A set of circular punchings, of the same bore as the armature diameter, was slipped over the outside, making good magnetic contact with the outside of the armature core, and thus forming a completely closed magnetic circuit around the armature winding. This armature was then driven at synchronous speed by means of another machine, two-phase alternating current was supplied to the collector rings, and direct current was delivered at the commutator. This was practically the equivalent of the so-called "permutator" brought out in Europe some years later. This machine was not successful, due to the change in lead at the brushes with change in load. In fact, it was quite sensitive to brush setting and the d-c. voltage regulation was relatively poor. This machine was operated for several months in the testing room and was then dismantled.

The foregoing covers pretty well the development of the 25-cycle converter. By 1896, this type of machine was becoming fairly well established and by 1898, with improved dampers, began to be recognized as a thoroughly commercial machine. There were instances where even the 25-cycle converter gave trouble, which, in some cases, could not be explained away. Most of the converters at that time were operated from engine-type alternators and it was recognized, possibly somewhat dimly at first, that the generating conditions had something to do with converter troubles. It was recognized by a few engineers that where two generators would not operate satisfactorily in parallel, there was good reason to suppose that synchronous converters, operated from these machines, might not act very well either; but such cases were rare, for 25-cycle engine-type generators usually ran in parallel quite successfully.

Another condition, which came up in some of the earlier attempts, was high ohmic line drop. A few cases were encountered where very severe hunting developed, even in converters with fairly good dampers. Various investigations showed that increase in line voltage helped materially and it began to be recognized that an unduly large transmission drop was harmful for converters. The writer made an extended series of tests at one time to determine the effect of resistance and reactance on the hunting of synchronous converters and other synchronous apparatus. The synchronous machine for this test was provided with very high damping power in order to obtain extra good conditions. The results in general indicated that a high ohmic drop between the generator and the synchronous load was harmful, depending upon the amount of drop. With 25 per cent ohmic drop, there was almost sure to be hunting, even with an extremely well damped machine. With 20 per cent ohmic drop, the hunting was the rule, rather than the exception; while with 15 per cent drop, hunting might occur, under some conditions, but in fact, it was the exception, rather than the rule. With materially less than 15 per cent ohmic drop in the circuits, apparently no hunting was produced.

Similar tests made with reactance instead of resistance, showed that, up to as high as 60 per cent reactance in the line, there was no material effect, as far as hunting was concerned. In consequence, the conclusion was reached that resistance, rather than reactance, was the harmful element in a large line drop.

The interesting fact about these results is that all

later experience which the writer has encountered agrees pretty closely with these early tests, and in a number of instances he predicted in a given system the conditions of load under which hunting would be first noticed and the results checked closely with his predictions.

After the development of the damper for converters, it was soon discovered that the amount of damping capacity on each machine had not only an appreciable effect in eliminating its own hunting, but it also had a damping effect on the system as a whole, and thus lessened the trouble on other converters. Just as it had been found that one sensitive converter connected to an apparently stable system might set other converters to hunting, so was it found that one especially stable converter with good dampers would tend to lessen the hunting on other converters. In one case, where 60-cycle converters without dampers had been installed, in connection with a waterwheel plant, there was, occasionally, slight hunting, principally under heavy load. The customer requested that an attempt be made to overcome this trouble. As additional converters were being installed, he was told that the trouble would be lessened when the new converters were put into operation. He was very doubtful about this, but upon the installation of the new machines, he reported that the hunting of the earlier machines was overcome. This was accomplished by putting quite ample dampers on the newer machines, thus introducing a steadying element into the system. In another case, in a large interurban railway system, it was found that the converter substations, farthest from the main generating plant, were subject to hunting on heavy load. In this case, a new substation on the same line, but still farther away, was equipped with converters which had very large damping capacity, and this quieted the substation which formerly had shown signs of trouble.

In 1898 and 1899 the 25-cycle converter was coming to the front very rapidly. In the latter year the Manhattan elevated railway in New York decided to electrify, and the first order for synchronous converters comprised 26 units, each of 1500 kw. nominal rating. Sometime later a similar order for the New York Subway consisted of 34 1500-kw. units. Within a comparatively short time, the total number of converters of this capacity for these two companies aggregated nearly 100. This was far above anything ever undertaken in the direct current generator line, and thus it may be seen that, even at this early date, about twenty years ago, the 25-cycle converter had already outgrown its direct-current competitor.

60-Cycle Converters

As was to be expected, the success of the 25-cycle converter would naturally lead to corresponding attempts to build 60-cycle machines. Here, however, much greater difficulties were encountered than in the 25-cycle, due to inherent limitations dependent upon the frequency. The first real 60-cycle converter built by the Westinghouse company was undertaken the latter part of 1896. This was a 250-kw., 14-pole, 514-revolution machine designed for a range of 230 to 340 volts, this range to be taken care of by variations in the a-c. supply voltage by means of an a-c. regulator. This machine was built without dampers, but, if the writer remembers rightly, it was operated from a generating system driven by a water wheel. Even at this time it was recognized that there was a difference in favor of waterwheel operated plants, for it was noted that certain converters which would not operate very successfully on engine-type generators, would operate much better on waterwheel plants. This was credited correctly to the more uniform rotative speeds of the waterwheels.

Shortly after this, a number of 60-cycle converters were put out, built by the Westinghouse and by the General Electric companies, and both had their troubles from hunting. However, other troubles developed, especially on 600-volt, 60-cycle converters. It was soon found that these machines were quite sensitive to flashing and ultimately it developed that this was due to certain inherent limitations in the machines themselves, as constructed in those days. The limiting peripheral speed of the armature cores and commutators was such that apparently good electrical and magnetic proportions were not obtainable. With the maximum allowable peripheral speed of the cores of those times; namely, about 7000 to 7500 feet per minute, the pole pitch of the machines was only about 12 inches and this did not allow space enough for both a good pole width and an ample interpolar space. If the interpolar space was made wide enough to give the desired commutating conditions, then the pole itself became too narrow to give the necessary pole width to prevent unduly high "peak voltages" between commutator bars. Six-hundred-volt direct current machines with less than 12 inches pole pitch had been good practise, but not with the limitations imposed by the 60-cycle frequency. In the direct-current machine, frequency and commutator peripheral speed do not appear as limitations to the same extent as in a synchronous converter, where the pole pitch and the distance between the adjacent neutral points on the commutator are fixed entirely by those two conditions. In the 60-cycle, 600-volt converter, with a commutator peripheral speed of 4500 ft. per minute, the distance between adjacent neutral points is $7\frac{1}{2}$ inches, regardless of the number of poles or revolutions. Within this short distance of $7\frac{1}{2}$ inches, it was then possible to use thirty-six commutator bars, for 600 volts. With this number of bars, the average volts per bar would be $16\frac{2}{3}$, which was believed to be permissible. However, with the relatively narrow pole face, compared with the pole pitch, as used in the early 60-cycle converters, the peak value of the voltage per bar was nearly double the average, and attained a dangerous value in regard to flashing, in machines of relatively large capacity.

However, if on these early converters the poles were made considerably wider, while retaining the same pole pitch, as was attempted from time to time, the dangers of flashing due to high voltage between bars, was lessened, but the neutral or commutating zones then became so sharply defined that it took an expert to operate the machines without dangers of flashing from improper setting of the brushes. It plainly was a case of "between the devil and the deep sea." Obviously, whichever way we moved we encountered either a serious sparking or a flashing condition. Evidently, there was something fundamentally wrong. Adding to the above difficulties the fact that 60-cycle engine-type generators, as a rule, were inferior to 25-cycle units, in constancy of frequency, ability to operate in parallel, etc., it may be seen that the 60-cycle problem was not any too promising for 600-volt work, even with dampers to prevent hunting. However, even when the damper was sufficiently developed on 25-cycle converters to show its capabilities, it was soon found that equally good results were not obtainable in 60-cycle converters, for it was not possible, with any of the designs brought out at the time, to apply anything like as large damping capacity, as was possible with 25 cycles. The 60-cycle poles were much smaller than the 25 cycle, thus allowing less space under the poles. Furthermore, with the higher frequency, the open armature slots produced quite heavy eddy current losses in the dampers themselves. Nevertheless, with all these disadvantages, dampers were applied to many of the early 60-cycle machines with material benefit, especially on units operated from waterwheels.

While the damper was being developed for 60-cycle converters, an interesting discovery was made by one of the engineers installing these machines on a Western transmission system. Here, there was considerable hunting at times, due, apparently to ohmic drop in the line. The generators were waterwheel driven. Hunting of the converters was more pronounced with heavy loads, indicating line drop as one cause of the trouble. In this converter station there was a 100-h.p. induction motor for driving certain apparatus. The installing engineer, noticed that hunting never occurred when this induction motor was connected to the circuit. In consequence, when hunting did occur with the motor off the circuit, he deliberately threw it on the circuit to determine whether it really did have any effect, and it was found that in every instance this stopped the hunting. Following up this clue, in another installation where there was severe hunting of, 60-cycle engine type generators, operated in parallel, and with converters operated from these generators, the writer purposely prepared a special induction motor to operate in parallel with the converters. This was a motor of a normal rating of 50-h.p., but which was operated under such increased voltage conditions that the magnetizing current was about equal to the rated full load current of the motor. In this way a machine of very low reactance was obtained. This motor was also made with relatively small slip. When this machine was connected to the above system in parallel with the converters, it invariably stopped the hunting of the latter, even though there was hunting between the two generators which supplied the converters. For a time, this was looked upon as one possible solution of the hunting problem, but further perfection of the dampers on the converters themselves so far eliminated the trouble, that the induction motor method of damping was abandoned. This is simply given as an illustration of one of the methods which was attempted for overcoming this trouble.

However, taking everything into account, the 60-cycle converter was considered by many operators to be a rather questionable device. Many engineers were of the opinion that the defects were of too fundamental a nature to be overcome. However, the writer believed during all this strenuous period, that the limitations in the converter itself were principally those of experience and practise, rather than true physical limitations, and that advances in the art of construction would allow them all to be overcome in time. He therefore persistently advocated that the 60-cycle development be continued.

A next step, which was of material benefit to the 60-cycle converter, and also to the 25-cycle for that matter was the advent of the turbo generator. This eliminated the element of periodic frequency variations found with the engine type generators. This was of very considerable benefit, eliminating one of the main causes of hunting. However, even with this improvement, the 60-cycle converter was still considered more or less questionable, due to its sensitiveness to sparking and flashing.

While this early 60-cycle development was going on, other quite different developments occurred which have been of great value.

The 3-Wire Converter

In 1897, the writer, while studying some of the conditions occurring in synchronous converters, discovered certain curious characteristics. It was well known that if one lead of a circuit were connected to one of the d-c. brush arms of a converter, while the other lead was connected to one of the collector rings, a pulsating unidirectional e.m.f. could be obtained, varying from zero to a maximum represented by the d-c. e.m.f. of the converter itself. This is illustrated in Curve 1, Fig. 2. The writer was endeavoring to apply this characteristic in some way, and in his study he assumed the case where the one terminal, instead of being connected to the collector ring, or transformer terminal, would be connected to the secondary of the transformer some distance in from the terminal. It developed at once that this would also give a pulsating unidirectional e.m.f., as in the former case, but with lower peak value,

and with its minimum not quite down to zero. This is indicated in Curve 2, Fig. 2. Of course, the next step was to move still further in on the transformer, giving current conditions as in Curve 3. From this, it could be inferred, at once, that if the terminal were moved to the middle of the step-down transformer

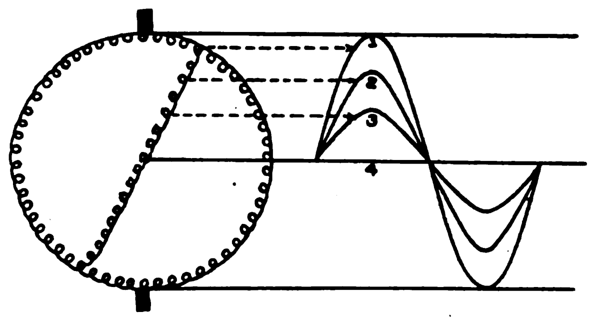

FIG. 2

coil, then the resulting e.m.f. would be constant in value and of half the value of the d-c. e.m.f. of the converter itself. In other words, this tap at the middle of the transformer secondary would give an intermediate voltage between the two d-c. brushes; that is, it constituted a three-wire machine. The writer immediately tested the scheme and found that it did give this result. Incidentally, on the heels of this discovery, a proposition came up where a customer wanted a three-wire system supplied by 60-cycle converters. The writer then proposed the use of a standard type two-phase, 60-cycle converter, but gave no explanation of the method by which it was intended to obtain the mid-voltage. The salesman on the job accepted all statements in blind faith and assured the customer that it could be done, and the customer also bought it on faith. The salesman then came to the factory to find what he had sold. He was soon convinced that he had made no mistake, but he refused to tell the customer how the result was accomplished until the machine was being installed. This method of supplying three-wire systems was used quite extensively in the following years.

THE INVERTED CONVERTER

Another development had to do with the operation of "inverted" converters. After converters had come into general use, a number of occasions developed where it was desired to operate them from d-c. to a-c., and, under certain conditions, more or less instability of speed was noted. This condition had been encountered quite early in the Westinghouse tests, and undoubtedly, similar conditions had occurred to all manufacturers. As early as 1895, a Westinghouse converter on test operating in connection with various other apparatus had suddenly speeded up, and before anyone could do anything, the armature windings had burst. This was blamed on the carelessness of the tester, in accidentally weakening or opening the field circuit, but he insisted that he had done no such thing and he was finally "let off" with a reprimand and told not to do it again. However, some months after this, a converter of fairly large capacity was installed in the company's power plant, tying the a-c. and d-c. power systems together. The first Saturday afternoon, after this machine was installed, the switchboard operator noted that the a-c. load on the plant had fallen to a point where the converter could carry it all and therefore he decided to cut out the a-c. generators and carry all his a-c. load through the converter. It so happened that this load consisted almost entirely of magnetizing current for a large number of induction motors which were running empty. The moment the operator transferred this load to the converter, the latter speeded up so quickly that it burst the armature windings before the operator could reach any disconnecting switches. The writer was at once called in and as soon as he heard the facts of the case, the explanation was simple enough and he stated that, of course, the converter would run away, for the wattless current in the armature would have a demagnetizing effect, just as in an a-c. generator, and therefore the converter had "killed" its own field. He was then asked what remedy could be applied to avoid future trouble. He said, offhand, that as the converter ran away, the remedy should be one depending upon change in speed. He then suggested that the converter be separately excited from a small generator driven in such a way that the exciting generator would speed up directly with the converter, and thus furnish greatly increased excitation with increase in speed. He suggested that this might be accomplished by belting a normally unsaturated exciter to the converter in question, or by exciting from a small motor-generator set, consisting of a d-c. generator driven by an induction motor, the latter to be connected permanently to the a-c. side of the converter. A motor-generator set of this description was soon "rigged up" and afterwards operated in connection with this converter with entire success and the trouble was never repeated in this plant. In later practise, the exciters for such inverted converters were usually direct coupled; that is, placed directly on a shaft extension of the converter itself. This use of a separate exciter was later adopted by other companies and is used today where inverted operation, with highly inductive loads, is one of the requirements. An interesting point in connection with this scheme is that although proposed off-hand some twenty-three years ago, no truly alternative method has ever been brought out.

VOLTAGE REGULATION OF CONVERTERS

After synchronous converters had become more or less accepted practise, it was found necessary to develop some means for varying the voltage of the direct current for railway work and for other kinds of service, such as three-wire systems. The latter was possibly the more pressing need. It was recognized quite early that the most effective method of regulating the d-c.

voltage in synchronous converters was by varying the a-c. voltage supplied. This led first to the application of "step-by-step" a-c. voltage regulators, and later to the use of "induction type" regulators. The General Electric Co. led in this latter practise, as it encountered the need for it most largely in connection with three-wire Edison systems. The first polyphase induction regulators were therefore applied by the General Electric Co. to the Edison three-wire plants. The Westinghouse company also built a large number of synchronous converter units with induction regulators for similar plants. This was quite firmly established practise for several years. However, the induction regulator, especially for a wide range of voltage, was a large complicated, and expensive piece of apparatus and electrical engineers were looking about for some means to overcome these objections.

About 1894, Mr. C. F. Scott, with the Westinghouse company, proposed in connection with compounding railway converters, that the a-c. voltage supplied to the converter be boosted proportionally to the load, by means of a small a-c. generator on the shaft of the converter, the field of which would be excited by the direct current from the converter itself. In this way, a true compounding action, such as in d-c. railway generators, could be obtained. While this particular scheme was never used, it contained the essential elements of a later development which eventually threw the induction regulator in the discard, as far as converters were concerned.

Previous to 1906, the British Westinghouse Co. had built a number of converters with small a-c. generators (or synchronous boosters, as they are now called) connected to the a-c. side, such boosters being separately, instead of series excited. They thus differed from the above scheme only in the method of excitation. In 1906 the Westinghouse company in America built a 500-kw. converter, along the same lines, for the Carnegie Steel Co., of Youngstown, Ohio. However, before this machine was put into service, this type was suggested to the engineers of the New York Edison Company as an alternative to the induction regulator scheme. Its possibilities so appealed to them that they placed an order for a comparatively large machine, in the latter part of 1906. The records indicate that this was the first synchronous booster converter put into service in this country and it thus represents the real beginning of the modern booster type converter in this country.

About 1907, the General Electric Co. brought out the so-called "split-pole" converter, in which the ratio of the a-c. to the d-c. voltages of the converter itself was varied by changing the field flux distribution; and soon the usual fight was "on" between the two companies, regarding their respective methods of voltage regulation. Whatever the merits of the methods, as understood at that time, one definite result was that the polyphase induction regulator soon dropped out of sight, as far as new synchronous converter work was concerned.

As to the relative merits and demerits of the two methods, the split-pole arrangement (or regulating-pole arrangement, as it properly should have been called) required no auxiliary machine, but on the other hand, it was inherently larger than the booster type and it was not well adapted for certain conditions of operations. There were points in favor of each type of machine, but with the coming of the commutating-pole construction, the synchronous booster type presented very material advantages, as the regulating-pole type of converter became unduly complicated with the addition of commutating poles, or their equivalent. In consequence, the booster type eventually won out.

In the synchronous booster type, two general arrangements were put on the market: First, the Westinghouse type with the a-c. regulating generator connected between the collector rings and the armature winding of the converter. In this type, the booster was necessarily of the rotating armature type, with a stationary field, just like the converter itself. In the second type, put out by the General Electric Co., the booster was of the rotating field, instead of the rotating armature type, and was connected between the transformers and the collector rings of the converter. In general, it was placed outside the synchronous converter bearing, on an extension of the armature shaft. There were arguments as to the relative merits of these two constructions. However, the rotating armature type of booster eventually proved to have enough advantages to dominate the situation, so that this type has been adopted almost exclusively. Apparently compactness, general simplicity and neatness of appearance of this arrangement had much to do with its adoption as a general standard.

However, it must not be overlooked that other methods for varying the d-c. e. m. f. of converters had been proposed and used quite extensively. The principal one of these had been used for a great many years in compounding converters for railway service. From the very first, in synchronous converter work, it was recognized that the power factor of the alternating-current input to the converter could be controlled by varying the excitation of the synchronous converter field. It was also known, even before this, that the power factor of the current in a transmission system had a direct influence on the voltage regulation at the end of the transmission line. With these two facts put together, the conclusion was reached that if a converter was given increased excitation, with increase in load, for the purpose of changing the power factor, the effect of the improved power factor would be to give a more uniform or even a rising voltage at the point where the load is taken off. Therefore, with this in view, the writer suggested, very early in the work, that converters should be compounded for the purpose of maintaining more uniform voltage. In-

dependently, Mr. R. D. Mershon went a step further and proposed the use of additional reactance in the transmission line, in order that the change in power factor could produce a still greater range in voltage. According to Dr. Steinmetz, the General Electric Co. at about the same time had been working along the same lines and had actually built heavily compounded converters for a certain railway application, which machines, however, were destroyed by fire before they were put into operation. Thus, it may be seen that this was a live subject and many people were working on it at the same time. Eventually, this arrangement narrowed down to the use of reactance on the a-c. side of the converter for compounding purposes.

An interesting feature in connection with this compounding was the doubt cast upon it in many large installations. On the Manhattan Elevated and the Subway synchronous converter installations, the customers' engineers were exceedingly doubtful regarding the practicability of series coils for improving the voltage regulation on the d-c. system. The Westinghouse company practically insisted upon putting series coils on these machines, claiming that the future growth of the service would necessitate the compound winding. This was then accepted, with the proviso that these machines have such heavy shunt windings that they could be operated as shunt machines, purely. The converters were built and operated in this manner for some five or six years and then, with poorer voltage regulation due to increase in service, the customers' engineers proposed to put the series coils in circuit, but *to shunt them down to half strength*, as they feared to use full strength. After a couple of years of operation in this manner, they removed the shunts and operated with full series and with correspondingly improved results. This same attitude held in various other places, while in some large plants the converters were ordered specially without any series winding whatever.

Further 60-Cycle Developments

Returning again to the 60-cycle development, it was mentioned before that the introduction of the turbo generator represented considerable improvement in the operation of these machines. However, the most serious limitation in the 60-cycle machines was in the small pole pitch and the small distance between neutral points, as explained before. Meanwhile, there had been considerable development in armature and commutator constructions, and finally the writer took it upon himself to urge a quite radical step in the 60-cycle converter development in the way of very materially increasing the peripheral speeds of both the armature core and the commutator. According to his analysis, a 25 per cent increase in the pole pitch would work wonders in the machine, for all this increase, with a given interpolar space for good commutation, would appear as increased pole width. For instance, with an interpolar space six inches wide for good commutation, and the pole itself six inches wide, making a pole pitch of twelve inches, a 25 per cent increase in pole pitch would mean that the pole could be increased to nine inches in width or would be 50 per cent wider than before. This would represent a very big improvement in the magnetic conditions, reducing the maximum voltage per bar very greatly. Also a 25 per cent increase in commutator peripheral speed would allow a corresponding increase in the number of commutator bars per pole, thus further reducing the volts per bar. These radical steps were taken and this development probably represented the greatest single advance in the 60-cycle synchronous converter design. In the General Electric Co. 60-cycle designs, a similar increase in pole pitch was adopted, but apparently this was considered ample improvement, without increasing the number of commutator bars. The writer is not prepared to say that this conclusion was a wrong one. Anyhow, both companies built more successful 60-cycle converters in consequence of the change in pole pitch, and the flashing troubles, except those due to unusual conditions, disappeared to a great extent. However, in spite of this improvement, these synchronous converters still were comparatively large machines with many poles for a given capacity, and while they more nearly approached the 25-cycle machines in characteristics and perfomance, they still were not considered entirely competitive. It took one more very important step to bring the two frequencies more nearly together.

Commutating Poles in Converters

This next step consisted in the introduction of commutating poles. The commutating-pole construction had been developing for a number of years in direct-current generators and motors and in railway motors, but up to the period of 1910 to 1912, the converters had been practically exempt from this development. There was a good reason for this, however. In the d-c. machine, commutation was a more serious limitation than in the converter, for the large, low-speed converters of that time, in general, had extremely good commutating characteristics. The writer and Mr. F. D. Newbury brought this matter out fully in a paper before the Institute in 1911,* explaining why commutating poles were not considered necessary in existing types of low-speed machines. However, in the discussion, the writer brought out clearly that the real field for commutating poles would be found if the synchronous converter speeds were so increased that commutation became a true limitation.

This is what actually happened a short time afterwards, for soon a rush began toward very much higher speeds in converters, so much so that the high-speed designs could not possibly take care of the commuta-

*Interpoles in Synchronous Converters, A. I. E. E. Transactions, Vol. XXIX, 1910, p. 1625.

tion problem without commutating poles. Both 25-cycle and 60-cycle converters shared in this increase in the speeds. The larger 25-cycle machines had their speeds doubled in a number of cases, by halving the number of poles. In the smaller 25-cycle machines, this could not be done because the number of poles was already as small as could be made, practically. Consequently, the smaller 25-cycle converters did not share to any extent, in the decreased size and cost and in the improved performance of the larger machines.

In the 60-cycle development, however, all the machines, from the smallest to the largest, had a relatively large number of poles and thus there could be a material decrease in the number of poles throughout the whole line, with correspondingly increased speeds, improved performance and decreased size and cost. The improvement in performance of the 60-cycle machines was considerably greater than on the 25-cycle, with increase in speed. In the former 25-cycle converter, the iron loss was a relatively small proportion of the total losses, usually being less than the armature copper loss. Increase in speed represented decrease in both iron and copper loss to a certain extent. In the 60-cycle machines, however, the iron loss in the older machines was relatively high, being sometimes from five to ten times as great as the armature copper loss. Doubling the speed, for instance, reduced this iron loss to practically one-half, or a very much greater percentage of the total loss than in the corresponding 25-cycle machine. In consequence of this and other gains, the 60-cycle machine was improved in efficiency to a greater extent than in the case of the 25-cycle, and was brought so close to that of the lower frequency machine that it became seriously competitive, especially when transformer efficiencies were also included. The gain in cost of the 60-cycle machines was also apparently greater than in the 25-cycle machine, and this also brought them closer together. In fact, the gain in cost and performance in the small 60-cycle machines was enough to make them more than competitive with the corresponding 25-cycle machine, so that for these reasons, as well as certain others, they have practically succeeded in driving the small 25-cycle converters out of the market. Thus, due to improvements in generating or supply conditions, certain radical changes in design, and the addition of commutating poles, the 60-cycle converter has changed, from what was considered a questionable machine, to a most serious competitor of the 25-cycle line. Improved types of dampers have also been a part of this development. In the older types of machines, the 25-cycle units with larger available space on the fields, could have very effective dampers, whereas the 60-cycle was somewhat handicapped in this respect. With the development of complete cage types of dampers, very much like those in the secondaries of cage-type induction motors, both 25-cycle and 60-cycle damping conditions were improved, but the 60-cycle were improved much more than the 25 cycle. This was therefore another step in advance.

Starting of Synchronous Converters

There is another part of the synchronous converter story, which as yet, has hardly been touched upon. This refers to the methods of starting and synchronizing such machines. One method of starting, namely, that used on the Chicago World's Fair exhibition machines, has already been referred to. This consisted in the application of relatively low voltage to the collector rings of a converter, and bringing it up to synchronous speed, after which it was transferred to full supply voltage. This method was practically the same as in present day practise, except that the starting device was somewhat more complex in having several steps, whereas at the present time, rarely more than two steps are used, namely, a starting position and full running position. This early method was not considered practicable, due to the fact that the "pull" on the supply system was thought to be excessive. Voltage regulation for generator systems in those days was entirely by hand and the throwing on of large inductive loads, such as converters at standstill, represented a very difficult condition, especially with the small generating plants in use in those days. At the present time, with the huge plants in use, a converter even though of the largest commercial size, may represent only a relatively small percentage of the power plant capacity.

To overcome the difficulties from a-c. direct starting several methods were devised and used quite extensively. The Westinghouse company in 1895 began using induction motors for starting synchronous converters. The first time that this method was put into service was on a 500-kw. converter in the power station of the Niagara Falls Power Co. This machine, as already mentioned, was one of the World's Fair 500-h. p. machines reconstructed into a 600-volt, 500-kw. machine. A six-pole induction motor was direct connected to the shaft of the converter for bringing it up to speed. It was thought at that time that the problem of starting from rest and speeding up was the serious one, and that as synchronous speed was approached, the current "pull" would not be very serious. However, actual operation on this Niagara converter indicated that the starting motor preferably should be able to pull the converter up to true synchronism. In consequence, on future designs the Westinghouse company installed starting motors which could accomplish this result. This was done by making the starting motor with two less poles than the converter itself, so that the synchronous speed of the starting motor was higher than that of the converter. Various methods were adopted for bringing the converter to exact synchronous speed and holding it there for an interval long enough to allow it to be thrown on the line without disturbance. In some cases, the no-load

losses in the converter, when excited to normal voltage were just sufficient to give load enough to obtain the required slip on the induction motor to hold the converter at approximately its synchronous speed. However, it was an unusual case when this came exactly right. The starting motor had to meet two conditions, namely, it had to have enough torque at standstill to overcome the friction-of-rest of the converter, which sometimes was quite high. As a second point in the speed-torque curve, it had to develop just torque enough at the synchronous speed of the converter to hold a reasonably stable or constant speed at this point. Not infrequently, it was impossible to get a speed-torque curve of the induction motor, which would meet these two conditions, without the aid of auxiliary appliances. For instance, with a six-pole converter and a four-pole starting motor, the motor had to run at two-thirds speed, that is, 33⅓ per cent slip, for synchronizing the converter. Even with a straight line speed-torque curve, this meant that the standstill or starting torque could be only three times the synchronizing torque, and in many cases, this was not sufficient to overcome the friction at start. By supplying higher voltage to the starting motor, a higher starting torque could be obtained, but the torque at two-thirds speed would be increased correspondingly, and consequently, the converter would reach stable speed at some point considerably above that required for synchronizing. One remedy for this in some cases was to greatly overexcite the converter, increasing its no-load losses and thus increasing the slip of the starting motor. This, however, meant throwing into synchronism with the line at considerable over-voltage. A second way of accomplishing the desired result was to throw a small resistance load across the d-c. end of the converter, thus pulling down its speed the required amount. Another way was to connect a transformer, with a cast iron core, across the a-c. side of the converter. All these methods had to do with starting motors with "cage" type secondary windings. In some few cases, starting motors with wound rotors and regulating resistances were used, but this scheme in general, was so much more complicated than others, that it was not used. The synchronizing difficulty, just described, generally occurred only with converters having six poles. With eight-pole converters and six-pole starting motors, the conditions were much more satisfactory, and in general, the higher the number of poles the easier it was to get good synchronizing conditions. However, this method of starting did not apply at all to four-pole converters, for this meant two-pole starting motors and the conditions for synchronizing would have been very difficult. In the later years of the starting motor method, commutator type single-phase series motors were used in some cases for starting, with means for readily adjusting their speed. These could be used with four-pole converters, and therefore were of especial advantage in smaller 25-cycle converters.

The disadvantage of the motor method of starting, in general, was that the converters had to be synchronized with the a-c. system, before throwing in. One advantage of this method was that the polarity of the converters always came right. However, the objections to synchronizing were considered as quite serious and eventually the method, in general, was abandoned, except in special cases.

A second method of starting, which was used in a variety of ways, consisted in bringing the converter up to speed by means of direct current. This method was used more extensively by the General Electric company than by the Westinghouse company. One method was to bring the converter up as a direct-current motor connected to the d-c. system where power was available from other sources. However, in railway work, the d-c. voltage supply often was so variable that it was most difficult to hold the converters anywhere near constant speed after bringing it up. In consequence, synchronizing and throwing into circuit was sometimes a tedious matter. To overcome this difficulty, in some cases the converter was brought very slightly above synchronism by the direct current, disconnected from the d-c. system, and then switched over to the a-c. system as it dropped through synchronism. A third method, which was also used quite extensively, consisted in the use of special sources of d-c. supply, such as motor-generators or storage batteries in the synchronous converter station. The source of supply being of practically constant voltage, there was no great difficulty in holding reasonably constant speed at synchronism, and throwing it on the a-c. system was comparatively easy. This scheme required synchronizing devices just like the starting motor scheme, and moreover, the synchronous converters came up with the right polarity. Where there was a large number of converters in one station, the cost of the motor-generator set, or other means for getting a constant voltage supply, was oftentimes no greater than that of starting motors on each converter.

In starting synchronous converters on direct current, there was one condition which was sometimes encountered, which was a source of more or less trouble. In some instances the step-down transformers, which supplied a converter, were connected permanently to the collector rings of the converter, without switches, all switching being done on the high-tension side of the transformers. In such cases, the low-tension, or secondary windings of the transformers were liable to form more or less complete short circuits across the d-c. brushes of the converter, depending upon how the collector rings were connected to the winding. In two-phase machines, with taps at 180 deg. points on the winding, it is obvious that with these taps in line with the brushes, the direct current supplied for starting could go, to a great extent, through the transformer, instead of the converter windings. In such cases, the

converter was liable not to start. With six-phase converters with diametral connections, the same conditions held. In consequence, with such connections, it was sometimes necessary to help the converter off by mechanical means. Of course, when once in motion, the current into the transformer would be immediately decreased. In six-phase machines with d-c. starting, double-delta connection to the transformers was generally used to prevent severe short-circuiting of this nature. In three-phase machines, dead short circuits by the transformers were not possible, for there were no taps across a diameter, and always part of the armature winding had to be in circuit. Double-delta connection with six phase is, of course, the equivalent of three phase, with respect to short-circuiting. However, even with three-phase converters, the short-circuited affect of the transformers with this arrangement was very considerable. For instance in the 1500-kw. converters for the Manhattan Elevated, motor-generators of 50-kw. capacity were provided for starting the 1500-kw. converters. On shop test, these starting sets were entirely ample for starting the converters, but here the lowering transformers were not connected to the converters. When installed in their substations, however, it was found that these 50-kw. units were very heavily overloaded at times in starting the converters, due to the short-circuiting action of the transformers. Tests were made to determine what influence the position of the collector taps had on the starting torque and current, and it was found that as far as the synchronous converter was concerned, its torque varied over a wide range, depending upon the position of the taps, and in all cases, it was considerably lower than when no transformers were connected. In consequence, to obtain the necessary starting torque, a very greatly increased starting current was needed, thus overloading the starting sets. This difficulty was overcome on the corresponding New York Subway converters by installing starting sets of double the capacity.

However, many years ago, the present method of direct starting by alternating current supplied to the synchronous converter collector rings was used, first on a small scale and afterwards on large machines, because it represented, wherever it was practicable, a cheaper and somewhat more convenient method than any of the others. Although this scheme was developed first by the writer and shown in the Westinghouse exhibit at the World's Fair, as already described, the General Electric Co. was earlier in the field with it on a commercial scale. This method of starting, at first, was considered as more or less of a hardship, as far as the supply system was concerned, but with the early development of an operative voltage regulator for the supply generators, the General Electric Co. was able to make headway with this method.

As the power systems grew in capacity and in size of units, they presented easier and easier conditions, as far as starting converters was concerned, and therefore, this method came into greater and greater use until it practically superseded all others. This method has the advantage that synchronizing apparatus is not needed, and, while it can come up with the wrong d-c. polarity, yet by means of "slipping a pole" this can be corrected very easily. In consequence, the method is, in general, quite satisfactory.

In some cases, in recent years, a combination of the motor starting method and this direct a-c. method has been used. In this special method, the supply current is fed through the primary winding of a starting motor and then to the synchronous converter armature. The starting motor is thus in series with the synchronous converter, and at start and during acceleration a relatively small current flows in the synchronous converter armature, but this current is large enough to produce a quite heavy torque in the starting motor. The small current in the armature of the converter is insufficient to reverse the polarity of the synchronous converter field, so that as the machine comes up to speed, it excites itself with its normal polarity, and when synchronism is reached all that is necessary to do is to short-circuit the induction motor element.

COMMUTATION

The problem of commutation was never very serious in the synchronous converter except in some of the later synchronous booster types where special conditions are found.

One reason why the commutation on the synchronous converter has been a simpler problem than on the d-c. generator is that the magnetomotive force of the armature is relatively small, being the resultant of the alternating and direct currents in the armature, whose magnetomotive forces are in opposition. In consequence, at 100 per cent power factor conditions, the resultant m. m. f. averages only about 15 per cent of that which the same winding would give as a d-c. generator. In consequence, the magnetic field, due to the armature, in which the commutating coils are short-circuited, is smaller than in a d-c. machine, and converters without commutating poles can commutate from 30 per cent to 50 per cent more current than the corresponding d-c. machines. Of course, in practise, converters were not built with this margin in commutation, for their ratings were increased, with a given armature winding, thus taking up a good part of the margin.

However, when it comes to flashing, converters have often proved to be more sensitive than d-c. machines. There have been several reasons for this. In the first place, being tied to an a-c. system, the converter, on a d-c. short circuit, not only could act as a d-c. machine, but could take current from the a-c. supply system, thus giving a very high peak current. In the second place, on a sudden application of heavy load, or on a short circuit,

part of the current, at least, is due to the machine acting as a d-c. generator and, in consequence, the armature m. m. f. is increased enormously over that as a converter. Moreover, under this condition, tests have shown that the converter may tend to hunt badly for a moment. This hunting simply means that the m. m. f. of the armature is rising to a relatively high value, first in one direction and then in the opposite direction, with accompanying field distortion, etc. This explains a rather curious condition, which was noted very many years ago; namely, that converters frequently would flash worse after the d-c. breaker was opened on a heavy load or short circuit, than they did in the moment of application of the load. The sudden load would produce the conditions for momentary hunting, but very often this hunting would not really begin until the breaker came out. In consequence, any flashing due to the hunting action would thus occur after the d-c. breaker was out and the apparent cause of the flashing had been removed. This action was quite clear from some shop tests made to determine the effect of opening the d-c. breaker when a converter was carrying a very heavy overload. The conditions in the tests were such that hunting could be readily determined. It was found that the hunting began the moment a very heavy load was opened by the breaker, and on a well damped converter it lasted for three or four "beats" approximately. In some cases, the hunting action was so violent that there was great tendency to flash at the brushes during this period. Obviously, under such conditions, anything that would lessen the hunting tendency would reduce the tendency to flash. Proof of this was furnished in a curious way in the case of commutating-pole converters, as will be explained later.

When it came to commutating-pole converters, the problem of commutation was even easier than on d-c. commutating-pole machines, except in those cases where the speeds were very greatly increased, accompanying the addition of commutating poles. As was explained before, in the application of commutating poles for synchronous converters, the speeds were doubled, in many cases, in order to improve the performance and lessen the cost. This doubling of the speed made the inherent commutating conditions much more difficult than before and a condition was reached where commutating poles were a real necessity, in order to obtain good commutation, as the commutating constants were about twice as high as in the former non-commutating machine.

A curious situation arose in connection with the early application of commutating poles to synchronous converters. It was well known that in direct-current commutating-pole machines, it is bad practise to surround the commutating pole with any closed low resistance electric circuit, as this acts as a damping circuit to make the commutating-pole flux more or less sluggish, so that it cannot follow quick changes in the load. Naturally it was assumed that in the synchronous converter similar conditions should hold. In consequence, it was assumed that the copper dampers on the main poles of the synchronous converters should not enclose the commutating poles. In other words, a complete cage damper should not be used. The writer recommended this practise* and apparently no one took exception to it. However, later actual operating conditions indicated just the contrary. In one case where a number of large synchronous converters were to carry 300 per cent short-time loads, there was bad flashing when the breakers would come out. The service engineer then put a short-circuited winding on the commutating poles, as an experiment, and found that the flashing was reduced to a certain extent. Tests were then made with full "cage" dampers on the poles of certain converters, these dampers necessarily completely enclosing the commutating poles. These machines flashed to a less extent than any of the others, thus showing that a closed circuit around the commutating pole was more of an advantage than otherwise. The explanation of this was then apparent from tests made to determine hunting conditions when an overload was thrown off, as already described. According to the calculations, the complete cage damper had about twice the damping effect of other types of dampers, and in consequence, the hunting, with sudden removal of load, was very much diminished. Therefore, the reduction in the hunting tendency apparently very much more than counterbalanced any bad effect of the low resistance circuits around the commutating poles.

This effect of the complete cage damper in preventing flashing is apparently much more pronounced in commutating-pole machines than in the old non-commutating-pole type for the following reasons:

In the commutating-pole converter, the magnetomotive force on the commutating-pole winding is comparatively small, as it must overcome only the small resultant armature reaction, averaging about 15 per cent of the d-c. plus about 20 per cent commutating field. This winding thus is made about 35 per cent as strong as the m.m.f. of the armature itself, considered as a d-c. machine. The corresponding commutating-pole m.m.f. of a d-c. machine could be about 125 per cent. It may thus be noted that the commutating pole m.m.f. of the average converter is only about one-third that of a corresponding d-c. generator. Here is a source of possible trouble; for, if for any reason, such as hunting, the resultant armature m.m.f. rises to a value comparable to that of a d-c. machine, it very greatly overpowers the commutating pole winding, and in consequence, magnetizes in the opposite direction through a good magnetic circuit. The commutating-pole flux thus may not only be reversed, but may rise in the wrong direction to a value which will give most vicious sparking, thus tending to produce flash-

*Discussion of "Interpoles in Synchronous Converters" loc. cit.

ing. In consequence, when a commutating-pole converter hunts badly, with the resultant m.m.f. rising to high peak values, there is a very great tendency in such machines to flash during such hunting. In consequence, anything which will reduce hunting will lessen this flashing condition. Therefore, the complete cage damper, as described before, with its ability to reduce very much the hunting tendency, has been quite effective in reducing flashing tendencies.

When it came to building "booster" type converters capable of giving a fairly wide range in voltage, a new difficulty was encountered, particularly in commutating-pole machines. An analysis of the armature conditions showed that under different loads with different "boosts" and "bucks" the resultant armature m.m.f. is not proportional to the current output of the machine. In consequence, it is not practicable to excite the commutating poles in series with the leads from the commutator, as in the ordinary converter. Neither will a shunt winding or direct combination of series and shunt meet the required conditions. In consequence, it has been necessary to develop very special regulating methods for exciting the commutating-pole windings for the synchronous booster type of machine. This has been a quite difficult problem, but eventually practical schemes were developed which enabled the commutating poles to be excited to a suitable value at all times. This has been one of the most difficult problems encountered in recent synchronous converter work, not due to any misunderstanding of the problem itself, but because no simple, easy method for accomplishing this result could be developed for quite a long time.

Commutators, Brush-holders and Brushes

From the standpoint of the commutator itself, the greatest development in recent years has been toward rigid constructions with higher peripheral speeds. With decrease in the number of poles and increase in the revolution per minute for a given output, the number of brush arms has decreased and the diameters of the commutators have decreased materially and the lengths have increased. A smaller diameter, with a higher peripheral speed and a greater length, means a materially more difficult mechanical construction, and this has been one of the serious problems in synchronous converter construction. The currents per brush arm have increased from 400 or 500 amperes up to 1500. This development has been accompanied by a certain amount of service trouble, as short-time shop tests cannot possibly bring out all the difficulties nor show how to overcome them permanently. However, enormous progress has been made in this matter and, presumably, the commutator situation is as good at present as in the past.

As to d-c. brush-holders, these have also gone through considerable development. In the early days, the problem was simpler than at present, for various reasons. In the first place, with lower currents per brush arm, there were fewer brushes per arm and less difficulty in obtaining average distribution of current among the brushes. With increase in current per arm, this problem has become relatively more difficult. In the second place, brushes of somewhat lower resistance have come into use and these have made the problem of distribution of current also more difficult. In the third place, with the coming of commutating poles there has been the necessity, in large converters, for development of brush lifting devices in connection with bringing the converters up to speed by the direct application of alternating current. In the old non-commutating-pole converters, the coils short-circuited by brushes were located in a relatively large interpolar space, with no iron directly over them. In starting and acceleration, the synchronous converter armature is simply the primary element of an induction motor, the field structure being the secondary. A rotating or traveling flux is set up, but in the vicinity of the coils short-circuited by the commutator brushes, this flux is of quite low value in non-commutating-pole machines due to there being no iron over the coils. In consequence, the short-circuiting effect of the brushes was not seriously harmful. In the commutating-pole machine, however, especially in large sizes, the commutating pole itself, during starting, furnishes a good magnetic path directly over the short-circuited coils, and in consequence, a quite heavy flux is established at these points. This develops quite large e.m.f's. in the short-circuited coils, with consequent heavy sparking during acceleration. For this reason, it has been found desirable to install brush-lifting devices to take care of the starting. When it is considered what a large, complex structure the brush-holder system forms in a large converter, it may be appreciated that this brush-lifting device adds very considerable complication and this has been one of the difficult problems in modern design.

Collector Rings and Brushes

Taking up next the question of collector rings, it would appear, offhand, as if the collector rings represent a comparatively easy problem. But in fact, it has become one of the truly difficult problems in the converter design, especially in recent years. Just to look at the collector and to note its functions, one would say that it is simply a matter of building several rings and putting on suitable brushes; but the matter goes far beyond this. The quantity of current to be handled is one of the sources of trouble, especially in the modern high-speed machines. When one considers that the total current to be handled by all the collector rings is practically three times the current delivered by the direct-current end (or neglecting efficiency, $2 \times \sqrt{2} \times$ d-c.) one can appreciate that the problem is largely one of quantity of current. However, the commutator handles the direct current twice, so that the total current handled by all the collector rings is approxi-

mately one and one-half times the total handled by the commutator. Yet, one usually looks upon the collector as being, naturally, a small inconspicuous part of the converter, whereas the commutator is one of the large important parts. It is this heavy current to be handled which has been at the bottom of nearly all collector ring difficulties in converters.

Very early in the development, converters were made either two-phase or three-phase; that is, with four collector rings or three. In this case, however, as all the rings are connected to one common winding, two phase is really four phase, and therefore, we may say that the early converters were either three-phase or four-phase. In the earliest calculations of the losses in synchronous converters, as already described, the three-phase machine showed 57 per cent of the copper losses of a d-c. armature winding, whereas the two-phase (or four-phase) showed 38 per cent. Obviously, the losses decreased with increase in the number of phases, or collector rings. Mr. R. D. Mershon worked this out at a very early date, and his calculations showed that with six-phase the losses were about 26 per cent, and that with enormous further increase in the number of collector rings, the losses would be decreased to 12 per cent. The general conclusion was that six rings represented a very considerable gain over four rings, but that it would not be worth while to go further than six. Mr. Mershon, the writer believes, was the first one to propose the use of six collector rings for synchronous converter work. However, this suggestion was not adopted until some years later, as there was apparently no particular advantage, in the early machines, in going beyond three or four rings. However, when quite large 250-volt machines came into use, as for Edison three-wire systems, the General Electric Co. adopted the six-ring arrangement, with transformers connected in double delta. It was not until a considerable time later that the simpler arrangement of "diametral" connections, now used so generally, was adopted. This latter arrangement was so simple that it gave an impetus toward the six-ring arrangement, which has brought it into quite general use, so that at the present time practically all converters are made six-phase. In the earlier work, the General Electric Co. adopted three-phase quite generally, whereas the Westinghouse used four-phase. Here was one case where the two-phase, so-called, had some advantage over the three-phase, but in going to six-phase (this is in reality a true three-phase, as far as the supply system is concerned), the advantage was in favor of the three-phase system.

In considering the collector rings themselves, the earliest types were made in the old-fashioned way, entirely enclosed on the sides, by the intervening insulating barriers, and therefore, with no ventilation except at the wearing surface of the rings. Copper leaf brushes were used, with relatively small contact drop, and therefore for moderate current capacities the losses were not high. However, with more difficult conditions, it was soon found that there was undue heating of the rings and the "open" type of collector was developed, in which the rings themselves were carried on open arms or spokes, so that the air could circulate freely. This enormously increased the carrying capacity of the rings and was a big step in advance. As a rule, several leaf brushes were used on each ring, as it was found that the ordinary brush could carry only about 200 to 250 amperes and very often the current per ring was several times this. A curious thing developed early in this work in regard to collector ring "wear." It was discovered that in some cases the rings would get "out of round" in a peculiar way. In a six-pole machine, there would be three high spots and three low spots on the ring, equi-distantly spaced; in an eight pole machine, four highs and four lows, etc. As soon as this was noticed as a serious defect, the cause was also recognized, for similar conditions had occurred in rare cases in rotating armature alternators, in the early days. The difficulty was not due to actual mechanical wear of the collector rings, but to burning under the brushes. It was recognized in a general way, long years ago, that a current passing from a brush to a commutator or ring in motion would tend to burn or "eat" away the brush surface, but not burn the ring to any extent; while in passing from the ring, or commutator, to the brush, the former would burn but not the latter. In the commutator, both actions take place due to both polarities being on the same commutator, and therefore, the effect is not usually noticeable. However, in the converter collector the current passes alternately in each direction in the rings, but assuming a single brush on the ring the current would be from the ring to the brush in one part of the ring, representing one pole arc, and would be in the opposite direction in the part representing the next pole arc. Consequently, within a given segment or part, the current is always in a given direction with respect to the brush and the ring. In consequence, in one segment the ring would tend to burn away, while in the next segment it would not. Consequently, if there were any burning of the rings, they would tend to get out of round, with as many low spots as there are pairs of poles. In some of the early converters, in laying out the brush spacing, accidentally the brushes were so spaced, with respect to the rings and the poles, that this burning action was accentuated, while in other machines, the spacing of the brushes was such as to give pretty uniform burning tendency over all the ring. In consequence, in some machines the rings would run out of true, while in others they would not. As soon as this became of sufficient importance to attract attention the difficulty was overcome by remodeling the brush supports and respacing the brushes. It was also noted that this action was particularly bad with very high current densities, and in such cases, the brush capacity was increased materially to lessen this effect.

The copper leaf brushes, being very flexible, could follow quite easily any slight variations out of true. Moreover, with low contact drop and the good ventilation of the open construction, the rings ran at relatively low temperature. Consequently, undue expansion did not come in as a factor, as has proved to be the case in some of the latter work. However one serious objection to the copper brush was that its wear resulted in a deposit of fine copper dust over everything and considerable attention was required to keep the parts clean and to keep the brushes just right. However. this method of operation lasted until comparatively recent times, when the "metal graphite" brush came in.

Many years ago, certain brush manufacturers in Europe produced graphite brushes with fine metal particles in them, which appeared to have very good carrying qualities, with low contact resistance; this latter being about one-fifth that of an ordinary carbon brush. With such brushes available, the manufacturers of synchronous converters undertook to use them on collector rings to overcome the objectionable features of the copper leaf brushes. These brushes were tried on quite a number of machines of different types, with both favorable and unfavorable results. It was found that the current densities, claimed practicable for these brushes, were, in general, much too high for American practise, and therefore, much larger brush capacities had to be adopted. Special brush holders had to be devised to meet the brush characteristics and a number of new difficulties were encountered which had not appeared with copper brushes. One of these was the effects of irregularities in the collector rings themselves. With copper brushes, as stated before, the rings could runout of true slightly, without having any appreciable effect. It was soon found, however, that with the metal graphite brushes, the rings could not be out of true, to anything like the same degree, as the brushes could not "follow" the surface properly and maintain sufficiently intimate contact. In other words, there was a "heel-and-toe" contact when the rings were out of round, with momentary local high current densities between the brush and the rings, with corresponding tendency to burn.

Also, with the higher contact brush resistance, there are considerably greater losses in the rings and brushes than with copper brushes, and in consequence, greater heating of the rings results, accompanied by greater expansion. As the rings, especially in the larger machines, must be of some "spider" type construction for ventilation purposes, it has been a serious problem to design rings which would not warp out of round with increase in temperature. A very considerable amount of difficult engineering has been carried on, to overcome the various troubles and to maintain, at the same time, good ventilation. In the recent years of synchronous converter work, there has been, possibly, no more difficult problem than this one of collector rings with graphitic brushes.

The foregoing pretty nearly completes the technical story. Something further might be said regarding special constructions of machines, such as very small converters, high voltage machines, etc.

In the very small synchronous converter, there has been possibly more trouble, in proportion, than in any of the larger sizes. This is partly due to the fact that in the small machine there is insufficient room for good size dampers, without making the machine unduly large. Such machines also appeared to be very sensitive to prime mover and transmission drop conditions, possibly on account of the small damping capacity. Some years ago the writer made a small converter of about 1½ kw. of the induction type, as already described. The principal purpose in this was to make a machine which absolutely would not hunt under very bad supply conditions. This little machine was later tried out on a generator plant where the generators themselves would not successfully parallel with each other, and yet it operated without any hunting whatever. Of course, being of the induction type, its power factor was comparable with an induction motor of about the same capacity. This was a most interesting little machine, and the writer has always believed that something further could have been accomplished with this principle.

In high voltage railway work, which has developed in recent years, there has been a call for synchronous converters of 1200 and 1500 volts and many outfits of this nature have been built. For 60 cycles, it has always been the practise to couple two machines in series, as it appears to be physically impossible to make a good 1500 volt, or even 1200 volt, 60-cycle converter with one commutator. Two-commutator machines have been proposed, but apparently this leads to considerable complication, so that the two-unit arrangement is the only one which has been commercial.

In 25-cycle converters, it has been practicable to build single machines up to 1500 volts with first-class operating characteristics. However, apparently there has been no attempt, up to the present, to operate two of these in series, commercially, to give 3000 volts.

Two-phase, three-phase and six-phase converters have been considered. Obviously, at some time in the development, single-phase converters necessarily came up for consideration. Very early in the development, the analysis of the losses showed that, when operating on single-phase, a synchronous converter would have considerably greater armature copper losses than on direct current alone. Consequently, this method of transformation was not considered as economical. However, from time to time, cases came up where single-phase operation was necessary, under emergency conditions, and in one case, a moderate size converter was operated for several weeks on single-phase supply with apparently no harmful effects. However, it was noted, in a large synchronous converter, transforming

from d-c. to single-phase, that there was considerable vibration of the dampers, these eventually becoming so loose that their supports had to be changed to more substantial ones. It was recognized that this was due largely to the backward rotating component of the a-c., m.m.f. the magnetizing effects of which were very largely neutralized by the dampers in the poles. This introduced a double-frequency current in the dampers themselves, which set up vibration. Apparently, however, when these dampers were properly constructed, a well proportioned single-phase converter would operate just about as well as polyphase, except for higher losses and other inherent conditions.

In conclusion of this paper, something might be said in regard to recent growth of the converter business. As already explained, at the time of the Manhattan Elevated and the New York Subway work, the 1500-kw., 25-cycle units had the "call" and it was felt, at that time, that while larger units might be used occasionally, the field was not large enough to call for much larger capacities. However, a few years later, 2000-kw. units were bought on a comparatively small scale, and then a few 3000-kw. were built. It then developed in quite a short time that a still larger unit was advisable for the heavier service and the 4000-kw., 25-cycle machine came in with a rush, which size has proved very desirable for heavy work. On 25-cycles, many of these units have been built by both the larger manufacturing companies. However, little has been said about still larger units, so that apparently this 4000-kw. size seems to meet all the needs at present.

In 60-cycle units, some seven or eight years ago, there was a sudden increase to 1500-kw. as a standard unit, although occasionally before this, machines as large as 2000 kw. of the slow-speed type had been installed. With the coming of the higher speeds, commutating poles, etc., and improved constructions, the 1500-kw., 60-cycle converter has proved to be a good one for railway work, while units of 2500 kw., and even larger, have been used very extensively for lighting purposes, electrochemical work, etc. In consequence, the 60-cycle and the 25-cycle converters are coming closer together in sizes, as well as in performances.

As to the future, no one can say where the upper limit will be, in the capacities of synchronous converters. It is practicable to build any capacity that the electrical public will pay for, as it is simply a question of increasing the number of poles, and decreasing the speeds, until the desired capacity is obtained. It may be said that it is a question of cost entirely, and not of design. However, in 60-cycle machine, there is still opportunity for relatively higher speeds, as the number of poles for a given output is still much less than in corresponding 25-cycle machines. In the latter, apparently the upper limit in speed has either been reached or we are very close to it. In 60 cycles, we cannot say that we have yet reached the limit of speed.

This rounds out the story of the synchronous converter up to the present. The early part of the story may appear more interesting than the description of the later developments, possibly because the early stages in any development possess more novelty, and also it may be that we obtain a better perspective of the more distant period. The later developments were, in many instances, just as difficult as the earlier ones, but they were part of an old story.

The present high stage of development of the synchronous converter is necessarily the result of the cooperation, as well as the competition, of many able minds. The writer wishes it to be understood that his engineering associates, as well as the engineers of other manufacturing companies, should share in the credit for this great development. From the personal references in the body of the paper, it might be inferred that he did practically everything himself; on the contrary, except in the early stages, in many instances he acted largely in an advisory capacity in the various developments, thus keeping in close touch with the problems at hand.

TEST OF A NEW ELECTRIC LOCOMOTIVE

ONE of the five new electric locomotives built by the General Electric Co. for a new electrified branch of the Chicago, Milwaukee & St. Paul Railroad, was recently tested at Erie, Pa., the tests being witnessed by a large number of engineers and railroad men, including officials of the Chicago, Milwaukee & St. Paul, the General Electric Co., the Canadian National Railways, the Canadian Pacific, the Hydro-Electric Power Commission of Ontario, and others. The new locomotive which is of the gearless type is one of the most powerful locomotives in the world. It has 14 axles each of which carries a motor. It is equipped for operation at 3000 volts d-c. and has a capacity of 3240 h.p. It is 78 ft. long, 17 ft. high and weighs 265 tons, of which weight 229 tons is carried on the drivers.

These locomotives have been designed for handling in normal service a 12-car train weighing 960 tons, against a two per cent grade at 25 miles per hour. Tests have showed that the gearless type of locomotive has 10 per cent higher efficiency at 50 miles per hour than the geared type. These locomotives are provided with regenerative brakes by means of which current is fed back into the line by the locomotive when it is coasting on down grades.

JOURNAL
OF THE
AMERICAN INSTITUTE
OF
ELECTRICAL ENGINEERS

with which is incorporated the PROCEEDINGS of the A. I. E. E.

PUBLISHED MONTHLY BY THE A. I. E. E.
33 West 39th Street, New York
Under the Direction of the Publication Committee

CALVERT TOWNLEY, *President*
GEORGE H. HAMILTON, *Treasurer* F. L. HUTCHINSON, *Secretary*

PUBLICATION COMMITTEE
W. I. SLICHTER, *Chairman*
N. A. CARLE F. L. HUTCHINSON
W. A. DEL MAR HAROLD PENDER

GEORGE R. METCALFE, *Editor*

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

THE NEW JOURNAL

The JOURNAL, formerly called the PROCEEDINGS, appears this month in a new form. The changes in name, size, and scope constitute one result of the deliberations of the Institute's Committee on Development, which formulated recommendations embodying improvements in the activities of the Institute, based upon the response of the membership to the Committee's request for suggestions.

The numerous replies received from members, and the reports of meetings of the Sections of the Institute held throughout the country for the purpose of considering these matters, clearly indicated a very general demand that the Institute continue to publish a high grade electrical engineering periodical, including, however, not only material of the nature heretofore published and consisting principally of engineering and theoretical papers and discussions presented at the various meetings of the Institute, but also much additional matter, relating to progress in the art of electrical engineering, selected with the object of publishing in each issue something that will appeal to each reader.

The broadened scope of the publication is a logical step in the evolution of the Institute based on the constructive work of the past, the present purpose being to supply information that will enable the individual engineer to keep more fully informed of recent developments in the *theory* and *practise* of all branches of electrical engineering. Original papers on theoretical or experimental investigations, important inventions, discoveries and developments in the fields of electrical engineering and the related sciences, will continue to constitute the major portion of the JOURNAL. The high standard that has always been maintained in the contents of the Institute's publications will be continued.

The dimensions of the page have been increased to 9 by 12 in., the generally adopted standard size for technical periodicals. It is more economical to publish the same amount of material on pages of the larger size than on the smaller size heretofore used. The larger page also permits a more attractive typographical display, a better arrangement of tabulated matter, and the publication of larger illustrations. Many other professional societies have adopted substantially the same size, including the Institution of Electrical Engineers of Great Britain, the Engineering Institute of Canada, the American Society of Mechanical Engineers, the Society of Automotive Engineers, and the American Institute of Mining and Metallurgical Engineers.

The improvements in the JOURNAL and in other activities of the Institute, as recommended by the Committee on Development, reflect the trend of the times. The predominating idea of today is social progress. The engineer, because of his training and experience, is particularly well qualified to analyze facts and draw conclusions. There is a general feeling, however, that the engineering profession has refrained from contributing the complete service of which it is capable in the consideration of the great social and economic problems which underlie human progress, and which require for their solution the application of engineering principles and methods.

The leaders in the engineering profession are the men who have been most active in their respective professional societies. Their ability for effective collective effort has been developed to a large extent by their activities in the Institute and in similar organizations. The JOURNAL is one of the instruments provided by the Institute for the exchange of ideas and it affords an opportunity for the individual engineer to contribute for publication something of interest and value from his experience in exchange for the ideas which he receives from other contributors.

The Publication Committee will therefore be glad to consider for publication contributions similar in scope to those published in this issue, in which a beginning has been made in the direction indicated. Additional improvements are under consideration, the development of which must necessarily be gradual and within the available income of the Institute applicable to publicatons. It is expected that the future issues of the JOURNAL will constitute even more fully than the monthly PROCEEDINGS and the annual TRANSACTIONS have in the past, an authoritative history of developments in the electrical engineering art and the related sciences, upon which evolution in the electrical industry is based.

A. I. E. E. MEETING AT CHICAGO

The 357th meeting of the American Institute of Electrical Engineers will be held in Chicago, Ill., January 9, 1920, under the auspices of the Chicago Section and the Lighting and Illumination Committee. The Western Society of Engineers and the Chicago Section of the Illuminating Engineering Society have been invited to participate in this meeting.

The headquarters of the Institute during the meeting will be at the Western Society of Engineers' Rooms, 17th floor Monadnock Block, where the registration and afternoon technical session will be held. An informal dinner and the evening technical session will be held at the City Club, 315 Plymouth Court.

The subject of the technical sessions will be *Electrical Distribution for Street Lighting.*

The complete program is as follows:

PROGRAM

Friday, January 9, 10 a. m. At Headquarters

Registration.

Board and committee meetings.

Friday, January 9, 2 p. m. At Headquarters

The Series System of Street Lighting, by W. P. Hurley, Sales Engineer, Westinghouse Electric & Mfg. Co., New York.

Multiple Systems of Distribution for Street Lighting, by Ward Harrison, Engineering Department, National Lamp Works, Cleveland, O.

Friday, January 9, 6 p. m. Sharp

At City Club, 315 Plymouth Court.

All attending members and guests are invited to join in an informal fellowship dinner. 1.50 per plate.

Dinner 6 to 7 p. m.

Get together recess, 7 to 7:30 p. m.

Friday, January 9, 7:30 p. m.

At City Club, 315 Plymouth Court, 3rd floor.

Constant Potential, Series Distribution for Street Lighting by Chas P. Steinmetz, Consulting Engineer, General Electric Co., Schenectady, N. Y.

Discussion, bringing out experiences with recent modifications of the old standard distribution schemes.

Saturday, January 10, 9:30 a. m.
Inspection trips

(a) Recent Chicago municipal street lighting distribution work, and Northwest Station, Commonwealth Edison Co.

(b) Specially arranged trips by request of members.

FUTURE A. I. E. E. MEETINGS

Midwinter Convention, February 18-20, 1920. The Eighth Midwinter Convention of the Institute will be held in New York, February 18, 19 and 20, 1920. While the details of the program have not yet been completed the tentative arrangements may be summarized as follows:

Wednesday, February 18. The morning will be devoted to registration. In the afternoon members will be permitted a choice between inspection trips to points of engineering interest or attendance at joint session with A. I. M. E. The evening will be occupied by the President's address and presentation of technical papers.

Thursday, February 19. At the morning and afternoon sessions technical papers will be presented under the auspices of various technical committees.

Friday, February 20. On Friday two technical sessions are scheduled for the morning and afternoon. A Dinner-Dance will be held in the evening.

March 12, 1920, Pittsburgh. Meeting under auspices of Traction and Transportation Committee. Subject: Electric Traction.

April 9, 1920, Boston. Joint Meeting with the American Electrochemical Society. Meeting under auspices of Committee on Electrochemistry and Electrometallurgy.

May 21, 1920, New York. Annual business meeting of the Institute.

June 22 to 25, 1920. Annual Convention.

FUTURE SECTION MEETINGS

Boston.—January 6, 1920. Subject: "Electric Welding."

Indianapolis-Lafayette.—January 16, 1920. Joint meeting with other technical societies.

February 20, 1920. Subject: "Problems Confronting Electric Railroads."

Los Angeles.—January 20, 1920. Subject: "Automatic Substations."

February 17, 1920. Subject: "The Engineer in Industry."

Rochester.—January 23, 1920. Paper: "Ignition System" by Mr. Libby, of the Splitdorf Company.

Schenectady.—January 16, 1920. Address by Col. H. M. Waite, of Dayton, Ohio, on "Commission Manager Form of Government."

St. Louis.—January 28, 1920. Technical Story of the Synchronous Converter. Speaker: Mr. B. G. Lamme.

Fort Wayne.—January 15, 1920. Subject: not assigned.

February 19, 1920. Subject: Autogeneous Welding."

March 18, 1920. Subject: not assigned.

A. I. E. E. MEETING, DECEMBER 12, 1919

The 356th regular meeting was held in New York on December 12, 1919 at Institute headquarters, 33 West 39th St. President Townley called the meeting to order at 8:20 p. m. The first paper of the evening "Applicability of Automatic Switching to all Classes of Telephone Service" was presented by the author, Arthur Bessey Smith. He was immediately followed by Ralph Kelley who presented the second paper entitled "The Searchlight in the United States Navy." President Townley then called for a discussion of both papers in which the following men took part: Selby Haar, L. F. Morehouse, W. I. Slichter, Paul S. Clapp, Donald McNicol, F. L. Baer, A. B. Smith, C. A. DeGraaf, M. L. Patterson, E. J. Murphy, J. C. Ledbetter, R. A. Beekman, B. P. Beeler and Ralph Kelley. A number of slides furnished by the Chief of Engineers illustrating types of searchlights used in the Army were shown by Chester Lichtenberg and P. R. Bassett. The meeting adjourned at 11 p. m.

A. I. E. E. DIRECTORS' MEETING DECEMBER 12, 1919

The regular monthly meeting of the Board of Directors of the Institute was held at Institute headquarters, New York, on Friday, December 12, 1919, at 3:00 p. m.

There were present: President Calvert Townley, New York; Past President Comfort A. Adams, New York; Vice-President N. A. Carle, Newark, N. J.; Managers Charles S. Ruffner, Wm. A. Del Mar, W. I. Slichter, L. F. Morehouse, New York, Charles Robbins, Frank D. Newbury, Pittsburgh, Walter A. Hall, West Lynn, Mass., L. E. Imlay, Niagara Falls, N. Y.; Treasurer George A. Hamilton, Elizabeth, N. J.; Secretary F. L. Hutchinson, New York.

A report was presented of a meeting of the Board of Examiners held December 8, 1919; and upon the recommendation of the Board the following action was taken upon pending applications: 258 Students were ordered enrolled; 112 applicants were elected to the grade of Associate; 7 applicants were elected to the grade of Member; 5 applicants were transferred to the grade of Member.

Chairman Slichter of the Meetings and Papers Committee reported orally regarding the program for the January 9th meeting in Chicago, and for the Midwinter Convention in New York, February 18-20; also regarding tentative plans for the March meeting in Pittsburgh under the auspices of the Traction and Transportation Committee, and the joint meeting with the Electrochemical Society in Boston in April.

Announcement was made that the January meeting of the Board of Directors will be held in Chicago, on the morning of Friday, January 9.

Upon the recommendation of the Finance Committee, monthly bills amounting to $12,886.49 were approved.

The report was presented of the Joint Conference Committee of the Development Committees of the Founder Societies. In brief, the report recommended the formation of local affiliations, state councils, and a national organization consisting of representatives of local affiliated bodies and national societies. It was voted that the report be endorsed and referred back to the Institute's three representatives on the Joint Conference Committee, for such action in cooperation with the representatives of such other societies as endorse the report as may be necessary to put the recommendations into effect.

The Law Committee presented a report submitting proposed amendments to the constitution providing for the division of the

country into geographical districts and the election of Vice-Presidents therefrom, as recommended by the Development Committee. It was voted that the proposed amendment be approved subject to revision by legal counsel.

A petition for authority to organize a Student Branch at the University of Wisconsin, Madison, Wis., was granted.

In addition to the above, many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the JOURNAL under suitable headings.

EDISON MEDAL AWARDED TO W. L. R. EMMET

At the meeting of the Board of Directors of the American Institute of Electrical Engineers held December 12, the Edison Medal Committee reported that the Edison Medal for the year 1919 had been awarded to Mr. W. L. R. Emmet, "for inventions and developments of electrical apparatus and prime movers." Arrangements will be made for the presentation of the Medal to Mr. Emmet at a convenient later date.

The Edison Medal was founded by the Edison Medal Association, composed of associates and friends of Mr. Thomas A. Edison, and is awarded annually by a committee consisting of twenty-four members of the American Institute of Electrical Engineers "for meritorious achievement in electrical science, electrical engineering, or the electrical arts."

William LeRoy Emmet, engineer and inventor, was born at Pelham, N. Y., July 10, 1859, son of William Jenkins and Julia Colt (Pierson) Emmet, grandson of Robert and Rosina (Hubley) Emmet, and great-grandson of Thomas Addis Emmet (q.v.), the first one of the family in America. The latter was the distinguished Irish patriot and leader in the Society of United Irishmen in 1798, and an elder brother of the ideal patriot of the Irish race, Robert Emmet, who was executed in Dublin in 1803 Thomas Addis Emmet came to America in 1804 and soon became a leader of the New York bar. His son Robert was a prominent lawyer and judge in New York City.

Mr. Emmet was educated at schools in Canada, New York, and Maryland, and subsequently entered the United States Naval Academy, where he was graduated in 1881. He served as a cadet midshipman until 1883 at Annapolis and on board U. S. S. *Essex*, and re-entered the navy as junior lieutenant in 1898, serving as navigator on the U. S. S. *Justin* during the period of the Spanish war.

His principal civil employment has been with the Sprague Electric Railway and Motor Company and the General Electric Company. He has achieved fame as an electrical engineer and as an inventor, and has obtained many patents for inventions in electricity, mechanics, and thermo-dynamics His most important electrical work has been in the development of the general use of alternating currents and in the invention and design of machinery to further the practical application of alternating currents, while his most important mechanical work has been in connection with the development and introduction of the steam turbine. He designed and directed the development of the Curtis turbine by the General Electric Company, a very large work, every detail of which was radically new, and which was carried on with almost unprecedented rapidity, He designed the machinery for the first ships driven by electric motors; and he was the first serious promoter of electric ship propulsion, conducting a series of experiments with the United States Collier *Jupiter* which are destined to be epoch making.

He is the inventor of several types of transformers, including a form of air-blast type which has been extensively used; of several types of insulation of alternators, and of other details which have met with general acceptance. He is the inventor of the oil switch, a device which is now almost universally used in large electrical work. After experimentally investigating the possibilities at Brooklyn and Niagara Falls, the heaviest circuits then existing, he was the first to design and use switches of this type. The varnished cambric cable which is widely used is also an Emmet invention.

He is the inventor of the vertical shaft steam turbine of which a very large number have been built; and many details of turbine design in general use are to his credit. His achievements have been those of an engineer and a pioneer of new methods rather than those of an inventor and much of his most original and most useful work could not be effectively patented nor perhaps even classified as invention. Most of his work has been connected with operations of the General Electric Company and has been done in close association with other G. E. engineers; and he has made it his special business to find new scope for the talents and facilities which the G. E. organization affords.

Mr. Emmet is the author of "Alternating-Current Wiring and Distribution" (1894) and of numerous important papers presented before the American Institute of Electrical Engineers and other engineering societies. He is a member of the American Philosophical Society, American Institute of Electrical Engineers, American Society of Mechanical Engineers, Society of Naval Architects and Marine Engineers, and of the Naval Consulting Board of the United States. He is also a member of the University and Engineers' Clubs of New York, the Mohawk Golf, Tobique Salmon, Mohawk, Edison, and Schenectady Boat Clubs. He received the degree of D. Sc. from Union College.

NEW YORK SECTION OF A. I. E. E. ORGANIZED

At the November meeting of the Board of Directors of the Institute a petition was presented, signed by more than one hundred members in New York City and vicinity, requesting authority to organize a New York Section, to be conducted under the same general plan as the other thirty-four Sections of the Institute. The Institute's Committee on Development had also recommended that a New York Section be formed.

The question of organizing a New York Section has been discussed from time to time for several years past, but as most of the monthly Institute meetings were held in New York City, the need for a local organization was not so urgent as in the other cities of the country. The growth of the Institute membership and the industrial developments throughout the country make it essential that in order better to fulfill its function as a national organization, an increasing number of meetings of the Institute, in addition to regular Section meetings, must be held in the various cities of the country.

This year, for example, an Institute meeting was held in Philadelphia in October, and others will be held in Chicago, Pittsburgh, and Boston during the months of January, March, and April, and no New York meetings are scheduled during those months. In order, therefore, that the New York members may retain all the advantages of membership it was considered by the petitioners desirable that a local Section be now organized.

The Directors approved the request and a special meeting for the purpose of organizing was held in the Engineering Societies Building, New York, on Wednesday evening, December 10.

The meeting was opened by President Townley, who in a brief address outlined the conditions which, in the opinion of the petitioners and other New York members, make it desirable to organize a New York Section at this time. Mr. Farley Osgood was then elected temporary chairman and presided during the remainder of the meeting.

Proposed by-laws, which had been prepared in advance by Secretary Hutchinson by direction of the President, and which were based upon the by-laws of the existing Sections of the Institute, were then presented and adopted. These by-laws provide that the officers of the Section shall be a chairman, a secre-

tary-treasurer, and an executive committee of five including the above named officers, which committee shall be the governing body of the Section; further, that the officers elected at the organization meeting shall hold office until August 1, 1921, and that officers shall hereafter be regularly elected at the annual meeting of the Section, in June, commencing with 1921.

A nominating committee of five was then appointed and a recess taken, after which, upon the unanimous recommendation of the nominating committee, the following officers were unanimously elected: Chairman, Mr. H. W. Buck; Secretary-Treasurer, Mr. H. A. Pratt; additional members of the Executive Committee, Messrs. E. B. Craft, W. S. Finlay, Jr., and Farley Osgood.

The future activities of the Section were not discussed in detail, but it is understood that the scope of the Section's work will be similar to that of the other thirty-four Institute Sections and it was the general sentiment of those present that the local organization will be decidedly advantageous to the membership of the metropolitan district. By thus organizing, the membership in New York and vicinity are placed upon the same basis in relation to the Institute as the membership in other Section territories.

ADDITIONAL GRADE OF MEMBERSHIP SUGGESTED

The following report of a committee of the Spokane Section, which was approved by the Section at a meeting held November 14, includes the recommendation that an additional grade of membership be established.

As the report was received after the Committee on Development had submitted its recommendations to the Board of Directors, it is published here for the information of the membership. Comments upon the suggestion are invited and should be forwarded to the Secretary of the Institute.

The matter will be considered as one of the topics for discussion by the Section delegates at the next Annual Convention.

REPORT OF A SPECIAL COMMITTEE OF THE SPOKANE SECTION A. I. E. E.

Recommending Changes in Grades of Membership

Your special committee appointed at the last regular meeting to consider the recommendations of the Development Committee and the suggestions resulting therefrom desires to report as follows:

[Note: The opening paragraphs of the report relate to the specific recommendations of the Institute Development Committee and have been referred to the proper committees for consideration.]

This Committee has discussed the present Constitutional requirements as to the grades of membership and dues (the latter having reference to the service furnished to the members by the Institute) and believes the time has come when the Constitution should be amended for the following reasons. Under the Constitution, engineers who have not been in the "active practise of their profession" for five years, but who are, nevertheless, engineers, are placed in the same grade, that of "Associate," with persons who are merely interested in the study or application of electricity and many of the young members believe that they should be in a grade, which would indicate that they are engineers. The present constitutional requirements that Fellows, Members, and Associates shall be equally entitled to all the rights and privileges of the Institute, except as regards holding office, is inequitable. While the policy of admitting engineers just started in the practise of their profession for less admission fee and less annual dues than those who have been in actual practise for five years or more is recognized as good, still the beginners in the profession should be willing to accept a service in keeping with the amount paid for it. Further, after an engineer has been in active practise for over five years he should be able and willing to pay the dues now paid by those of the grade of Member.

As a basis for discussion your committee offers the following suggestions:

There shall be established the grade of "Junior," a "Junior" shall be not less than twenty-one years of age, and shall be either;

(a) An electrical engineer by profession. As such he shall be qualified by experience to fill a subordinate engineering position, or he shall be a graduate in electrical engineering of a school of engineering of recognized standing.

(b) A teacher of electrical subjects.

The requirements for "Associate" (Section 6) shall be amended by eliminating "a" and "b".

The admission fee for "Juniors" and "Associates" shall be $5.00 and the annual dues $10.00.

After a "Junior" has been a member for five years, his annual dues will be $15.00 whether he transfers to the grade of Member or not.

The section of the JOURNAL containing matter relating to *Institute Affairs* and such other matter as shall be added shall be furnished free to those members paying annual dues of $10.00 and the section containing *Institute Papers and Discussion* shall be furnished upon request at cost. All members paying annual dues or $15.00 or over shall be furnished *both sections* free.

The TRANSACTIONS shall be furnished free to all members paying annual dues of $15.00 or over and at cost (average) or less to other members.

The full service of the Institute shall be furnished to Honorary members.

Nov. 14, 1919.

NOMINATIONS FOR INSTITUTE OFFICERS FOR 1920-21

As provided in Section 20 of the Institute By-laws, candidates may now be proposed for nomination for the officers to be filled at the next annual election in May, 1920, by the petition or by the separate endorsement in writing, of not less than fifty members. The petitions or separate endorsements must be in the hands of the Secretary not later than January 25, 1920. For the convenience of members, a form of petition has been prepared by the Secretary, and copies of it may be obtained upon application to Institute headquarters. Endorsements may, however, be made by letter if the form is not available. A member is not limited in the number of candidates he may endorse in this manner.

The officers to be elected are: a President and a Treasurer, for the term of one year each, six Vice-Presidents for the term of one year each, and three Managers for the term of four years each.

The Constitution provides that "the President, Vice-Presidents and Managers shall not be eligible for immediate reelection to the same office. A Vice-President shall not be eligible for immediate election to the office of Manager."

For the information of members, the full text of Section 20 of the by-laws, governing the proposal of candidates for nomination, is printed below:

Sec. 20. In addition to the names of incumbents of office, the Secretary shall publish on the "form showing offices to be filled at the ensuing annual election in May" provided for in Article VI of the Constitution, the names, as candidates for nomination, of such members of the INSTITUTE as have been proposed for nomination for a particular office by the petition or by the separate endorsement of not less than fifty members, received by the Secretary of the INSTITUTE in writing by January 25 of each year; provided, however, that any candidate proposed for nomination by petition may withdraw his name by written communication to the Secretary, and any name so withdrawn prior to the printing of the form shall not be published.

The names of such candidates for nomination shall be grouped

alphabetically under the name of the office for which each is proposed, and this by-law shall be reprinted prominently in the December and January issue of each year's JOURNAL, and shall be reproduced on the form above referred to.

ENGINEERING FOUNDATION

MENTAL HYGIENE OF INDUSTRY

FOR about a year Engineering foundation has been supporting researches in the Mental Hygiene of Industry under the guidance of Dr. Elmer E. Southard, of Harvard Medical School, a well-known psychiatrist. He has been assisted by Miss Mary C. Jarrett, a pioneer in psychiatric social work. From a progress report made to the Foundation December 11, the following notes have been taken:

A keynote paper for employment managers has been written by Dr. Southard, entitled "The Movement for a Mental Hygiene of Industry," and several other papers dealing with various phases of this subject are being prepared by Dr. Southard, Miss Jarrett and Miss Butler. The report suggests that the keynote and other papers, after approval by the Foundation's special committee be published in engineering journals and also in such journals as *Mental Hygiene* in order to secure concomittant recognition by medical men.

Miss Jarrett has been laying down lines for special courses to develop employment managers equipped with the new special knowledge. She has interviewed about 20 leading employment managers and has found them very receptive to the idea of supplementary training and of special work in mental hygiene for the employment manager group. She has been able to show that the psychiatrist and the psychiatric social worker are nowadays dealing with mild disorders, tempermental deviations, and slight eccentricities, namely, exactly the kind of thing with which industrial personnel has seriously to deal.

The respective advantages to different sides of the industrial personnel problem have been studied and the results embodied in the Keynote paper submitted to the committee. The psychologist will no doubt prove of greatest advantage in the hiring problem. The psychiatrist will prove to have wider scope in relation to grievances, complaints, dissatisfaction and unrest, so far as these are in part traceable to peculiarities and special conditions in individual workmen. The efforts of the psychiatric social worker will be directed especially to aid in tracing down the discharged cases and the reasons for discharge. The psychiatric social worker will often be able to solve the individual's problem so that that particular employee will not again be a problem for the industry in question, or perhaps for other industries.

NOTES FROM NATIONAL RESEARCH COUNCIL

THE CERAMIC INDUSTRY

The National Research Council and the American Ceramic Society have established a joint committee for promoting the investigation of scientific problems underlying the ceramic industry, especially by founding a series of research fellowships whose holders shall devote their attention exclusively to these problems.

The ceramic industries, including brick and tile making, and general crockery and glass manufacture as well as ornamental potteries, although among the earliest ones developed by man, have been the last of our great manufacturing industries to reach the status of an applied science. They have been based for centuries on rule-of-thumb methods, trade secrets, and individual artistry. As far as their artistic features go science can do little or nothing for them, but in all other ways it can be of great advantage to them and it is certain that an organized effort to develop the fundamental science of ceramics can have a great influence in advancing the industry.

INVESTIGATION OF FATIGUE OF METALS

An investigation of Fatigue Phenomena in metals under repeated stress as announced in the PROCEEDINGS for December, 1919, has just been started under the joint auspices of the National Research Council, Engineering Foundation, and the Engineering Experiment Station of the University of Illinois. The Engineering Foundation is providing $15,000 for two years for this investigation, and the Engineering Division of the National Research Council is acting in an advisory capacity, largely through its committee on Fatigue Phenomena in Metals. The experimental work is being done in the laboratories of the Engineering Experiment Station of the University of Illinois, under the immediate direction of Professor H. F. Moore, Research Professor of Engineering Materials and Chairman of the Committee above mentioned.

Plans are laid for a two years' program of tests, and apparatus and materials are already arriving for the tests. It is hoped to secure a considerable amount of data on tests of various metals including a number of tests of each metal to 100,000,000 reversals of stress. It is hoped to study the various short-time physical tests which are used for metals,—such as the impact test, magnetic analysis, and short-time bending tests,—to see whether any of these tests give reliable indices of the ability of the metal to resist fatigue under millions of repetitions of low stress. It is hoped that some reliable commercial test for this important property may be developed by this investigation.

A test party of four or five persons is being organized and the University of Illinois is fitting up a special laboratory with about 2500 square feet of floor space for the use of this investigation.

CURRENT ENGINEERING TOPICS

CONTINUANCE OF CONSTRUCTION DIVISION

At the time hearings were being held on the subject of Army reorganization the Chairman of National Service Committee of Engineering Council addressed the Military Affairs Committee of both Houses and General Pershing, directing their attention to the splendid record of the Construction Division, and urged that this Division be continued in substantially its present form so that it will be enabled to carry on the work that has been started, in the same efficient manner. Replies from the chairmen of both committees indicated that they realized the value of the Construction Division under its present organization and showed that they personally were in favor of maintaining this Division intact.

There is still a good chance that the Military Affairs committees of both Houses will recognize it as a separate corps. The officials of the Construction Division and practically all civil engineers that have had work with the Division in the various parts of the country desire that such action be taken. It is the general belief that the efficiency of the Construction Division will be impaired if it is returned to the Quartermaster General's Department or made a part of the Engineers Corps.

The points made against incorporating the Construction Division in the Engineers Corps or returning it to the Quartermaster's Department were that the engineers are the first to be sent to the front, whereas the duties of the Construction Division are at training camps, supply depots, etc. at a distance from the actual fighting. Thus it would be far removed from its administration, besides which such men do not have the kind of technical training that is required in the construction work. If the Construction Division was returned to the Quartermaster Depart-

ment it would soon swallow up that Department, especially if the proposed construction program of the Army is carried out.

The bill proposed by the General Staff is dead from a legislative standpoint as is the Dent bill and other drafts made along the lines of the General Staff bill. The Military Affairs committees are drafting entire new Army reorganization bills which it is expected will be introduced in the respective Houses shortly.

ESTIMATES FOR PUBLIC WORKS—FISCAL YEAR 1921

The Secretary of the Treasury has approved and forwarded to Congress estimates for next year which total the unusually large sum of $283,921,810. The appropriations for public works during the fiscal year 1920 total $93,872,092. The estimates for work of particular interest to engineers and constructors are as follows:

Construction of Government buildings, including purchase of sites, $1,332,775; marine hospitals and quarantine stations, $5,204,621; fortifications, $117,793,330; military posts, $14,225,251; rivers and harbors, $53,659,265; navy yards and stations, $20,606,000; Panama Canal construction and maintenance, $18,245,391; depots for coal and other fuels, $2,335,000; Reclamation Service, $20,134,000; $725,000 special appropriation for a fuel inspection system; $1,865,880 for the Bureau of Mines; $2,592,920, Geological Survey; $3,000,000 (approximate), Bureau of Standards.

HIGHWAY LEGISLATION

The original bill proposing to create a National highway system controlled by a Federal Highway Commission, which was proposed by Senator Townsend, has been practically abandoned because of the opposition which has developed. It is now believed that any plan for National highways constructed directly by the Federal Government will be unpopular with the states because only a limited portion of the state will be benefited directly by such highways. Further, the Government with its road building activities would be in competition with the states and the counties. It is believed that it will be easier for the Federal Government to hold the states up to a standard rather than to attempt to maintain the standard through its own work. No plans have been made to secure consideration of the Townsend bill at the present session of Congress.

Another highway bill which proposes a National Highway Department and Highway Commission has been introduced into the House, which aims to do away with the defects which have become apparent in the Townsend bill. It will bring the control of highway work more closely under the control of the states, at the same time giving enough Federal supervision to insure coordination and standardization in the work. The states are to be divided into ten regional areas with corresponding regional congresses having direct control of the work in their region but under the general direction of the National Highway Commission.

For the purpose of carrying out the provisions of this new act and as an initial appropriation for the creation of a National Department of Highways, the new bill proposes to appropriate $10,000,000. The Secretary of Highways would receive $12,000 per year, and each National Highway Commissioner would receive $6,000 per year.

CONVENTION OF NATIONAL DEPARTMENT OF PUBLIC WORKS ASSOCIATION

Willard Hotel, Washington, D. C.
January 13th-14th, 1920

The movement to establish a National Department of Public Works initiated by the technical men of the country, and which took definite form at Chicago last April, is now a live National issue. It is the first National campaign in which the engineers of the United States have united.

The convention announced as above has been called to intensify the interest in the movement, to broaden the scope of the organization, to discuss procedure, and to adapt our activities to the developments that have taken place since last April.

Effort has been made to invite all engineering organizations in the United States but it may be that some have been unintentionally overlooked. The National Public Works Department Association earnestly desires that all such organizations shall regard this announcement as a direct invitation to them to send delegates. All accredited representatives will be heartily welcomed.

The fundamental reason for a Department of Public Works is to secure efficiency and economy in the conduct of Government business. The Secretary of the Treasury recently submitted a $5,000,000,000 budget to cover expenses for the next fiscal year. There are few, if any, proposals in that budget that are not necessary to our general welfare. They will have to be either eliminated or pruned to meet financial limitations, but that process does not constitute a rational solution of the difficulty. We are paying too much for what we get and all measures of economy will be futile until we bring order and organization out of the chaos of our Departmental activities.

INTERNATIONAL ELECTRICAL EXPOSITION FOR SPAIN

According to report of the Bureau of Foreign and Domestic Commerce, Spain is planning for a large international electrical exposition at Barcelona. A permanent exposition is being erected which will probably be completed late in 1920 and the electrical exposition will probably be the first use made of the buildings.

Manufacturers of machinery are to be invited to furnish exhibits in the following groups: Group 1—Generation, transformation and accumulation of energy. Group 2—Transmission and distribution of energy. Group 3—Apparatus and methods of investigation, demonstration and measurement. Group 4—Electric lighting—electricity in the home. Group 5—Application of electricity to the manufacturing industries. Group 6—Application of electricity to traction. Group 7—Telegraphy, telephony and radio-telegraphy. Group 8—Application of electricity to medicine and hygiene. Group 9—Electrochemistry and electrometallurgy. Group 10—Electricity as applied to agriculture. Group 11—Application of electricity to the exploitation of the sub-soil. Group 12—Technical application of electricity.

THE STEEL BASING POINT

As a result of further hearings before the Federal Trade Commission, it has been conceded that there will be no abolition of long established practise of using Pittsburgh as a steel basing point. The interests that favor a single price basing point, notably the Western Association of Rolled Steel Consumers, base their claim on the allegation that Pittsburgh is in violation of the Clayton Act. This group has attempted to show that they pay a fictitious freight rate on fictitious transportation from Pittsburgh on steel produced through the Western district and for this reason they claim that they are unable to compete in the Eastern market, whereas the Eastern fabricators can place their products in the Chicago market on an even competitive basis. They declare that the public was taxed $30,000,000 a year through increased prices of manufactured steel.

Counsel for the Steel Corporation showed that since Chicago producers can only supply one half of the Chicago demand, the Pittsburgh price must dominate since it supplies the other half. There would be no advantage to the Chicago producers in selling at less than the Pittsburgh price when they could not profit by any extra demand so created. They naturally sell at the market price which is the Pittsburgh level. When producers can supply all the requirements of their own territory, the Pittsburgh basing point will cease as a result of natural laws. Other important steel producers have given testimony substantiating these claims.

AIRCRAFT STATISTICS IN THE NAVY

A very comprehensive report has been submitted by the Secretary of Navy covering activities through November 1st, 1919. This report shows the number, type and cost of all aircraft built, building, and under contract to be built, the number of and type of aircraft to be constructed in Government plants, for which material has been delivered or ordered.

The report contains details of facilities of every kind maintained wholly or in part by the U. S. Navy for procuring producing, inflating, operating, preserving and handling aircraft. This includes active and abandoned operations and covers the connection of each of the Navy bureaus with the operation in question. This report was prepared in response to an order from the Committee on Naval Affairs.

TECHNICAL WORK AT THE BUREAU OF STANDARDS

Bulletins on the progress of experimental work that has been started at the Bureau of Standards are as follows:—1. Radio Fog Signalling Experiments. 2. Standardization of Electron Tube Symbols. 3. Scientific Research on Electron Tube Amplifiers. 4. Magnetic Analysis. 5. Industrial Safety Standards. 6. Photoelectric Spectrophotometry. 7. Reinforced Conc ete Investigation. 8. Durability of Cement Drain Tile in Alkali Soil. 9. Investigation of Concrete Tanks for the Storage of Oil. 10. The Effect of Protective Coatings on the Strength of Manila Rope. 11. Investigation of Oxyacetylene Welding and Cutting Apparatus. 12. Strain Gage Measurements of 350-Ton Crane. 13. Locomotive Packing Ring Investigation. 14. Embrittlement of Lead by Corrosion and Its Relation to the So-Called Allotropy of Lead. 15. Weights and Measures Publications. 16. Assistance in Graduating of Anthropometric Instruments. 17. Graduation of Saccharimeter Scales for a Large Sugar Concern. 18. Testing of Hydrometers. 19. Meeting of Committee on Paper Specifications. 20. Investigation of Thermostatic Return Line Valves for Heating Systems.

Because of the current nature of these investigations the results are not generally put in printed form but complete data on the results of the work to date are always available on application to the Bureau of Standards or the National Service Committee in the Washington office of Engineering Council.

BOSTON-WASHINGTON SUPER POWER LINE

The following is a copy of letter which was sent to all organizations which are located within the Boston-Washington survey.

Because of the vital importance of this subject to all branches of the engineering profession, Engineering Council has urged that it be given careful consideration and support of engineering organizations and their individual membership throughout the interested districts.

It is a special note-worthy fact that in addition to inquiries from interested engineers within the districts that will be covered by the survey a number of inquiries have been received from engineers throughout the West and Middle West concerning this project.

It is especially an engineering project and needs the active support of the engineering profession.

INDUSTRIAL SAFETY CODE CONFERENCE*

A conference on Industrial Safety Codes was held at the Bureau of Standards, Washington, D. C., on December 8, 1919. In the absence from Washington of the Director of the Bureau, Dr. S. W. Stratton, the meeting was called to order by Dr. E. B. Rosa, who summarized the events leading up to this conference and referred especially to the proceedings of the similar conference held on January 15th, of which this in a sense was an adjourned meeting. The principal subjects which came up at the January conference were the reorganization of the American Engineering Standards Committee, and the question of whether the safety work of the Bureau of Standards should be conducted under the scheme of procedure laid down by that committee.

The last question was the subject of a letter ballot sent out in the spring, the result of which was a decided majority in favor of procedure under the plan of the American Engineering Standards Committee. This Committee has adopted since the January conference a revised constitution which opens its membership to other organizations in addition to the original five founder societies and three Government departments.

Dr. Rosa also announced the appointment of a General Advisory Committee on Industrial Safety Codes for the purpose of assisting the Bureau of Standards in deciding upon policies and procedure in its work on safety codes. He said: "The Advisory Committee recently appointed by the Bureau is not a managing committee. It is for the present merely an advisory committee for the Bureau of Standards."

Prof. Comfort A. Adams, Chairman of the American Engineering Standards Committee, then spoke on the work of that Committee and its recent reorganization. Membership in the Committee is now open to such organizations or groups of organizations of national scope as may be approved. The speaker stated that he would be superseded as Chairman of the Committee by Mr. A. A. Stevenson, and that the permanent Secretary of the Committee will be Dr. P. G. Agnew, at present in the Bureau of Standards. The headquarters of the Committee will be in New York City.

The procedure to be followed in the development and adoption of American Engineering Standards was then outlined. Committees to formulate standards shall be organized by suitable engineering societies, Government Bureaus or other bodies which shall be designated as sponsors and shall be responsible for the carrying out of the work. Such a Committee must include representatives of all interests concerned in the formulation of a standard, and upon completion of its work and substantial agreement upon the same, shall report to the sponsor body. If the latter adopts the standard it is forwarded to the American Engineering Standards Committee for approval, and when so aproved, shall be designated as either Recommended Practise, Tentative Standard, or American Standard. The Standards Committee will not itself pass judgment upon the details of the proposed standards but rather upon the composition of the Committee which has formulated the Standard or approved it. This Committee must not be confined to the membership of the sponsor body, but must include representatives of all interests concerned in the standard.

The status of industrial safety codes now existing was next discussed. Dr. Lloyd exhibited a number of charts on which it was attempted to show the scope of existing safety rules in the industrial field but exclusive of the subjects of transportation, mining and industrial hygiene. The relation of fire prevention to human safety was considered.

Dr. Chaney pointed out that a survey of accident records would show what hazards are greatest and consequently what industries are most in need of safety regulations. The method of administration of safety rules is of more importance than the contents of the rules themselves. Compensation laws have brought about an improvement in accident prevention work.

Mr. Collette referred particularly to the Boiler Code of the American Society of Mechanical Engineers and the recent work of that society in preparing an Elevator Code in cooperation with the Bureau of Standards.

Mr. Paine referred to the disadvantages of non-uniformity and of temporary rules and said that to have a satisfactory code it was necessary to have the cooperation of all interested.

The symposium on Methods and Policies to be Pursued in the Development and Introduction into use of Safety Standards was then presented.

The following resolution which was proposed and adopted by the Conference:

Resolved: (1) That the American Engineering Standards Committee be asked to request the International Association of Industrial Accident Boards and Commissions, the Bureau of Standards and the National Safety Council to organize a Joint Committee on Safety Codes, this committee to include representatives of these bodies and such others as they may consider advisable: (2) that this Joint Committee report upon the Safety Codes required, priority of consideration of the codes, and sponsor bodies for their preparation; (3) that this report be put in writing and placed not later than February 1, 1920, in the hands of the American Engineering Standards Committee.

Before taking the vote on this, however, another motion was passed confirming the result of the letter ballot taken last spring and expressing the decision of the conference that Safety Codes should be established under the procedure of the American Engineering Standards Committee.

It was pointed out that the American Engineering Standards Committee was not primarily interested in safety matters and that the Committee contemplated in the above resolution would be directly concerned in such matters and might well serve as a steering committee on safety code work. The opinion was freely expressed that such a committee should be a permanent one, that it should contain representatives of all interests involved in safety codes.

At a meeting of the General Advisory Committee of the Bureau on the following day the work of the proposed committee was further discussed and the opinion was generally expressed that such a committee, if made a permanent organization, would render the General Advisory Committee of the Bureau of Standards unnecessary.

INSTITUTE REPRESENTATIVES

The Institute, together with other national engineering societies, is represented upon a considerable number of committees, commissions, and other organizations formed for the purpose of cooperation upon matters of common interest. The terms of a number of these representatives have expired or are about to expire, and at the meeting of the Board of Directors held December 12, action was taken as follows:

United Engineering Society, Board of Trustees: Mr. Calvert Townley, whose term expires in January, was reappointed for a term of three years. The hold-over Institute representatives are Messrs. L. T. Robinson and Samuel Sheldon.

Engineering Council; Mr. H. W. Buck was reappointed and Mr. Charles S. Ruffner appointed, for terms of three years each commencing in February 1920. The hold-over representatives are Messrs. N. A. Carle, C. E. Skinner, and C. A. Adams.

Library Board, United Engineering Society: Mr. Edward D. Adams was reappointed for a term of four years commencing in January 1920. The hold-over representatives are Messrs. Samuel Sheldon, W. I. Slichter, A. W. Kiddle, and F. L. Hutchinson.

American Engineering Standards Committee; Mr. C. E. Skinner was appointed for a term of three years commencing in January 1920. The hold-over representatives of the Institute are Messrs. C. A. Adams and H. M. Hobart.

Commission of Washington Award: Professor Charles F. Scott was reappointed for a term of two years commencing in January 1920. The other representative of the Institute is Lieutenant-Colonel John Price Jackson.

A NEW WELDING PUBLICATION

The initial number of the *Journal* of the American Welding Society has made its appearance under date of October, 1919. It is published by the American Welding Society at 33 West 39th Street, New York, and is the official organ of the American Bureau of Welding in which a large number of technical societies and organizations is represented. The *Journal* presents a handsome typographical appearance and contains much valuable technical information on the art of welding. Welding has not developed as it should, for lack of a source of authentic information, which the new publication bids fair to supply.

PERSONAL

Manuel Cruzat, in conjunction with others, has formed the South American Translation Bureau, which will handle consulting work in regard to South American trade, and also advertising and technical translations, with the purpose of cooperating with the engineers, business men and manufacturers of the United States. The Bureau has opened an office at the Grand Central Palace, New York City.

George M. Brill announces that following an interruption of his consulting practise in Chicago including two years of war work he has resumed his practise in New York.

He will continue to specialize in the engineering of industrial plants and processes, improvements in operation and financial investigations. A temporary office has been opened in the Singer Building, New York, but after May 1st he will move into permanent quarters at the Guarantee Fifth Avenue Building.

Major John J. McConnell, former United States Constructing Quartermaster and Utilities Officer in the Construction Division of the Army, has been discharged from the Service, and is now located in Room 602, Commercial Bank Building, Alexandria, Louisiana, and will engage in a general contracting and engineering practise.

Gustav Hirsch, formerly Lieut. Colonel in the Signal Corps, has resumed a general consulting practise with offices at the Hartman Building, Columbus, Ohio. During his service he was division signal officer of the Thirty-Sixth Division, ten months of this service being in France.

Mr. M. C. Henderson, City Electrical Engineer of Dunedin, New Zealand, was a visitor at Institute headquarters on November 26.

Mr. Henderson while in the United States is visiting a number of the principal electrical manufacturing and operating companies.

ADDRESSES WANTED

A list of members whose mail has been returned by the postal authorities, is given below, together with the addresses as they now appear in the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

Lieut. Chas. H. Arnold, 1016 Myrtle Ave., Erie, Pa.
Robert F. Arnott, Amer. District Steam Co., No. Tonawanda, N. Y.
Jason L. Frye, Camp Kearny, Cal.
Colonel B. B. Hyer, Camp Wheeler, Macon, Ga.
Henry D. Lindsay, 232 Prospect Ave., Milwaukee, Wis.
Major Geo. C. Oxer, Florence, Ala.
Wm. A. Street, Gatun, C. Z.

The Committee on Classification and Compensation of Engineers presented to Engineering Council December 18, an interesting Progress Report which contained a proposed classification for engineers in federal, state, county, municipal and railway employment. This classification will be published in the near future. Adoption and use of a suitable classification of engineers throughout the country is fundmaental to intelligent consideration of compensation for various engineers, especially in Governmental employment, city, state and national.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months. during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

SERVICES AVAILABLE

ADVERTISING OR SALES connection in New York or metropolitan district, will be considered by commercial engineer. Twelve years successful experience in consulting, contracting, buying, selling, editorial writing and technical advertising. Expert in mechanical, steam and electrical equipment, wiring and piping for buildings and power plants. Exceptional ability, backed by common sense, initiative and ready adaptability to new conditions. Salary $4000. Salary and commission or bonus, considered. E-2001.

CONSULTING ENGINEER open for engagement to Utility or Industrial Concerns. 15 years superintendent construction and operation. 8 years consulting and designing industrial, power, railway and lighting systems. Efficiency engineer and fuel combustion expert. Rates and valuation. E. E. and M. E. Degrees. Minimum salary $6000. Correspondence solicited. East preferred. E-2002.

ELECTRICAL ENGINEER; technical graduate, with two years modern mechanical and marine engineering, two years manufacturing and six years commercial and efficiency engineering experience; also considerable experience in industrial haulage and handling of materials in large manufcturing establishments. Desires to locate in New York City, or vicinity. Single, age 33. Salary about $3000. E-2003.

ELECTRICAL ENGINEER, A.B. and E.E.; seven years experience with a large manufacturer of telephone apparatus; 8 years head of department of electrical engineering in a state university; has done much work of the Dean; desires teaching or commercial position. Minimum salary $4000. Salary scale too low at present location. E-2004.

ELECTRICAL ENGINEER; M. I. T. 1915; age 27, married; principal experience in engineering department, public utility; on central station design, office records, and data; qualified for an executive position. Excellent personality, energetic, initiative and will get results. Prefer New England or vicinity. Salary $3000. E-2005.

ELECTRICAL ENGINEER; technical graduate; ten years experience in design of electric control apparatus; eight years on staff of one of largest manufacturers of control equipment; two years assistant to consulting electrical engineer. Has handled estimates, specifications and engineering correspondence. Location immaterial. Age 38, married. Salary $3600. E-2006.

ELECTRICAL ENGINEER; technical graduate; age 26, ex-army officer; 2½ years practical experience; familiar with operation, installation, and testing of storage batteries, gas engines, rectifiers, motors, generators etc.; experienced in design of electrical circuits, power boards, etc.; desires position where initiative and ability count. Available immediately. E-2007.

ELECTRICAL ENGINEER; technical graduate, age 25. G. E. Test, Schenectady, Pittsfield and Lynn; experienced in modern shop manufacturing and production methods; familiar with textile industry; desires position in or near New England in either Sales or Industrial Engineering. E-2008.

ELECTRICAL ENGINEER college graduate, 28 years of age; experience in design and test of direct current motors and generators; short experience in power plant work and teaching, desires a permanent position where experience would be of practical use. E-2009.

ELECTRICAL ENGINEER desires position in Eastern Ontario, Canada; at present chief electrician large by-product coke plant. Ten years general steel mill construction and operating experience. Thorough knowledge of motor repair work A. C. & D. C.; and magnetic control. Ability to handle men; also to specify and purchase electrical equipment. Salary $3000. E-2010.

EX-ARMY OFFICER WANTS position as assistant manager or Commercial Engineer with Electric Light and Power Co. Capable of getting and holding business. Experienced in sales, power application, operating and construction. Salary $3600, to start. E-2011.

EXECUTIVE ENGINEER desires position as manager or superintendent of construction of electric light or railway properties, or as appraisal engineer on the valuation of public utilities or private plant. First class references backed by years of experience in the above lines. Minimum salary $3000 per year. E-2012.

GRADUATE ELECTRICAL ENGINEER, three years operating, testing, and maintenance of electrical distribution and machinery, one year light and power salesman; desires position where energy and ability will produce additional responsibilities. Age 25. Salary to start $1800. E-2013.

GRADUATE ELECTRICAL ENGINEER, American, age 30. Nine years experience steam electric power house construction, design and operation. Familiar with high tension, piping and steel layouts. Recently discharged from Army. Desires position in East. Available at once. Salary $2700. E-2014.

INDUSTRIAL-ELECTRICAL ENGINEER; 10 years experience in design, construction and operation of steel and industrial plants. Capable of assuming responsible charge of work. Married. Available immediately. E-2015.

MECHANICAL AND ELECTRICAL ENGINEER; Graduate, age 32; machinist by trade; five years general industrial experience, three years sales engineer with large oil company. Officers' Radio School, Columbia University, N. Y. Position desired in N. Y. or Pa. Can give best of references. E-2016.

PRACTICAL ELECTRICAL ENGINEER and construction man. Yale graduate. Married. Age 29. 5 years on station operating and construction 2 years on building construction and appraisal; and 2 years in charge of station design. Wishes position as Superintendent of Construction or Design Engineer. Salary $3000. E-2017.

PRODUCTION, MECHANICAL AND ELECTRICAL ENGINEER; technical graduate, practical experience from small jobbing to large manufacturing concerns. Modern methods of scheduling, planning, routing and controlling the production, payroll, distribution, cost and stores-keeping. Now production manager of large concern. Just installed and organized a system for above. Climate not agreeable. E-2018.

TECHNICAL MAN, age 23, 3 years college training in electrical engineering, two years experience on house wiring, two years electrical testing, for past 18 months assistant engineer in electrical construction division of large electric railroad. Minimum salary $1800. E-2019.

YOUNG ELECTRICAL ENGINEER desires position in medium sized industrial power plant to have charge of operating, care and maintenance. 7 years experience on A. C. & D. C. equipment of all kinds. Assoc. A. I. E. E. and member N. A. S. E. Age 22. Location preferred south or west. E-2020.

TECHNICAL GRADUATE; age 38, single, member; seventeen years experience design, operation and construction of central stations. At present with public utility company operating a number of electric light and ice plants. Will go any where. Salary six to eight thousand dollars per year depending on location. E-2021.

ELECTRICAL ENGINEER; university graduate; age 32; experience in design of power plants and substations, also in general engineering work and possessing executive and initiative abilities, would consider any proposition offered in New York City or its close vicinity. E-2022.

Electrical Engineer, age 36, technical graduate; twelve years experience with large hydro-electric company, covering nearly all phases of public utility service. Now in charge of all transmission and distribution lines and sub-stations. Desires position as superintendent. Energetic and good executive; good personality. E-2023.

Draftsman; five years electrical and mechanical experience, including plant layout work. Desires permanent position where initiative and ability are considered an asset. E-2024.

Electrical Engineering Graduate, age 24, desires position with small growing hydroelectric power concern in the Northwest. Experience in preliminary surveys, power calculations, etc. Was in charge of responsible engineering work in army as 1st Lieut. in Air Service. Available immediately. Salary $150. E-2025.

Graduate Electrical Engineer: Associate; age 27; married; three years practical experience in power plant, and sub-station designing; specialist on switch-board design and manufacture. One year Westinghouse apprentice. Position desired requiring executive ability. At present in employ of large Eastern electrical manufacturer. Middle West location preferred. Salary $3000. E-2026.

Electrical Engineer, technical graduate, age 25; desires position in station betterment and power development work, or with reliable consulting engineering firm. Approximately two years Westinghouse test and one year in engineering department, with responsible positions in both. Also some central station experience. References if wanted. Salary $2300. E-2027.

Electrical Engineering graduate, 1919, with degree of B.S. age 22, desires a position leading to experience in design or use of electrical machinery in industry or electric traction. Would also accept position with concern furnishing electric power. Have two years experience in testing d-c. machinery. Salary $30 per week. E-2028.

Electrical Engineering graduate, 1917; degree of B. S.; desires position with concern manufacturing electrical apparatus, which will lead to sales; would consider position with public utility corporation; several years varied experience in operating and testing electrical machinery. Location New York City or vicinity. Salary $30 per week. E-2029.

OPPORTUNITIES

University of Wisconsin, Electrical Engineering Department, desires to appoint before February an assistant or associate Professor of Electrical Engineering qualified to assume charge of the Central Station and Electric Railway Courses. An experienced engineer who has carried on investigative work resulting in contributions to the art is desired. R-2080.

University of Wisconsin, Electrical Engineering Department, will appoint in February an instructor in electrical engineering. Salary $1500-1800. for nine months school year. A man with an unusually thorough grasp of fundamental electrical theory and a few years of experience in the engineering or teaching field is desired. R-2081.

Efficiency Engineer, experienced in time study and rate setting. Location Cleveland, Ohio. R-2150.

Electrical Engineer Graduate with 1 to 3 years experience in meter, motor and miscellaneous testing, to organize and develop a meter and test department and assume full responsibility for the testing, calibration and proper operation of meters and relays in a large hydro-electric plant and a large Rotary Converter Sub-station; also to make motor and other tests in a large industrial plant. Good opportunity for a man with initiative and resourcefulness. Reply stating education, experience and salary expected. Location New York State. R-2152.

Electrical Tester, trade school or technical school graduate with some experience in testing all classes of A.C. and D.C. meters and A.C. and D.C. motors; to act as an assistant in the electrical testing department, duties of which are outlined above. Location New York State. Salary $90-120 per month. R-2153.

Designer & Detailer for Electric Traveling Cranes, with several years experience and familiarity with both mechanical and structural features. Opportunity for capable man to develop rapidly to chief draftsman. Location Pennsylvania. R-2161A.

Associate in Export Work; must be either electrical or mechanical engineering graduate; with considerable experience in power plant and electrical lines. Would be given an opportunity to take a $20,000 interest in the corporation and would be given charge of one of the offices in China. R-2171.

Chief Draftsman, technical education, and three or four years shop or drafting room experience on engine and boiler work. Location Cincinnati, Ohio R-2174.

Instructor in Engineering Mechanics, must have technical education. Department is being reorganized; good opportunity for the right man. Must report by February 1st, 1920. Location Connecticut. Salary $1500-1800 per year. R-2181.

Engineering Accountant capable of handling complete report work and distribution of labor and materials reports. Should have some practical knowledge of railroad work, both in the field and office and a good understanding of Interstate Commerce construction accounts. Two Openings. Location Middle West. Salary $175.00. R-2188.

Inspector of Engines and Turbines must have had practical experience in steam power plants. Technical graduate desired. Location Hartford, Conn. R-2194.

Electrical Engineers; technical graduates with one or two years experience, also recent graduates, for work in telephony. Location New York City. R-2197.

Engineer Executive to take charge of the design, construction, and installation of all machinery for four wireless stations of not more than 240 miles range. Location vicinity of New York. R-2207.

Assistant Professor of Electrical Engineering; several years of teaching experience. Duties will consist of class room and laboratory work, chiefly in electrical engineering, and including some work in physics. Location Baltimore District. Salary $2400 per year. R-2210.

Storeroom Executive capable of planning, directing and supervising all activities pertaining to automobile stores management in an operating organization and also in an automobile factory. Location Chicago, Ill. R-2213.

Power Salesman; graduate electrical engineer with at least four years experience in general electrical work. Permanent position. Good future. Location Easton, Pa. Salary $175-200 per month. R-2233.

Technical Translator must understand either French, Spanish or Portugese. Position is in editorial department of a large publishing house. Several openings. Location New York City. R-2235.

Electrical Draftsman for work on electrical design of generating and sub-stations. Experience in this work while desirable is not absolutely essential. Several Openings. Location Chicago, Ill. Salary $110-140 per month. R-2239.

Chief Draftsman; must be familiar with general machine design, and big and broad enough to handle problems of power and plant engineering. Office now employes about ten men. Excellent opportunity for future advancement. Location Massachusetts. R-2262.

Sales Engineer for special power plant auxiliary equipment. Headquarters at New York City. R-2268.

Assistant Engineer with mechanical and electrical experience for design, experimental and research work. Marine experience would be useful. Location Massachusetts. R-2269.

An Ambitious Man with about three or four years experience in designing of commercial electric motors, also specifications and production methods in manufacturing. Location Maryland. R-2273.

Draftsman, for Plant Engineering Division of Industrial concern; *Architectural*, experienced on reinforced concrete and steel building. *Electrical*, familiar with lighting and power layouts. *Pipe*, able to lay out service and hot water piping. *Mechanical*, general experience. Salaries in accordance with ability. Location, Conn. R-2285.

Instructor in Electrical Engineering in a Western University. Two years practical experience desirable; can begin duties at once. R-2288.

Chemical, Electrical & Mechanical Engineers, recent graduates, for work in lamp development laboratory. Openings for 8 or 10 men. Location New Jersey. R-2297.

Translator, Electrical Engineer preferred, who can rewrite French technical information into English. One who has received his education in France would naturally be preferred, but, it is not essential. Location New York State. R-2300.

YOUNG ELECTRICAL ENGINEER with industrial experience and some teaching ability for a teaching position that will pay from eighteen to twenty-one hundred dollars at the start; should be the kind of man who can get along with boys and influence them properly. Location St. Louis, Mo. R-2301.

RESEARCH ASSISTANT for University Engineering Experiment Station. Graduate study in Electrical Engineering, or experience in research essential. Location Illinois. R-2302.

MECHANICAL OR ELECTRICAL DRAFTSMAN for electrical heating appliances. Location New York City. R-2305.

INSTRUCTOR IN MECHANICS at a Middle Western University for next semester, beginning about February 10th. Salary will depend on qualifications; maximum $1900 for academic year. R-2310.

ENGINEER with broad experience in various industries for editing technical publications. Location South New England. R-2315.

ELECTRICAL DRAFTSMEN wanted who are familiar with electrical layouts for general industrial plant work and who also have a good knowledge of mechanical drafting. R-2324.

YOUNG GRADUATE IN ELECTRICAL ENGINEERING COURSE for valuation of telephone public utilities. Applicant must have had telephone engineering experience. Salary $125 to $150 per month and traveling expenses. Location Illinois. R-2329.

FIVE (5) YOUNG ENGINEERS interested in power house and sub-station work to lay out electrical circuits. This is a particularly good opening for men who have not finished their technical course. Permanent positions with unusual opportunities for advancement. Location Western Pennsylvania. R-2330.

MECHANICAL DRAFTSMAN wanted by well-established company, manufacturing a complete line of D.C. and A.C. generators and motors. Good opportunity for experienced man who is capable of working into position of assistant chief draftsman. Location Western Penn. R-2332.

OFFICE MANAGER for a manufacturing concern. Will have charge of all the clerical forces with the exception of those pertaining directly to the purchasing and selling departments, and also of the accounting, financial reports, credits, collections, etc. To qualify, applicant must be able to handle clerical forces and must be thoroughly posted on all matters pertaining to accounting and costs, as well as taxation. Salary $4000 per year up. Location Massachusetts. R-2342.

SALES ENGINEER to handle line of boilers, engines, power plant machinery and electric traveling cranes and hoists in New York City territory. R-2346.

INSTRUCTORS with practical experience in telephone and telegraph work, to teach fundamentals of Electricity four days and evenings. Two openings. Salary $25 per week and bonus end of year. Location New York City. R-2378.

ENGINEERS, ESTIMATORS, DRAFTSMEN AND INSPECTORS on laying out and inspecting underground and overhead distribution lines. R-2386.

OFFICE EXECUTIVE; must be high grade man thoroughly conversant with time, stock and cost records, familiar with accounting and experienced, if possible, in buying and selling. Location Michigan. R-2402.

ENGINEER with 3 or 4 years experience since graduation for testing laboratory. Work will be special investigations involving laboratory research work and also factory testing of electrical apparatus. Applicant must be above average in alternating current theory and must have had experience in test department of a large manufacturer. Laboratory experience in electrical measurements desirable. Location New York City. R-2403.

ELECTRICAL ENGINEER OR PHYSICISTS especially interested in illumination or photometry. Openings also for chemical engineers in research work. Positions are with a government bureau. Recent graduates considered. Salary $1200 per year and up. R-2404.

YOUNG ENGINEER of sound technical training desired in connection with the development of new high frequency electrical apparatus. Good grasp of physical and mathematical fundamentals important. Signal Corps experience useful. Permanency assured. Give details of training, experience and salary desired. Location New York City. R-2405.

JUNIOR RESEARCH ENGINEER; a long established industrial organization in a rapidly expanding field has an attractive opportunity for a young man of first-class ability and thorough training in electrical engineering or technical physics. Post graduate training desirable but not insisted upon. Prospects limited only by ability. Salary proportionate to education and record. Location New York City. R-2406.

DEVELOPMENT ENGINEER; young engineering graduate wanted for experimental development work on electrical apparatus. Distinctive opportunity for young man of energy, resourcefulness and supervisory capacity to grow with new engineering developments of a fundamental nature. Salary determined by qualifications. Location New York City. R-2407.

RECENT GRADUATES for statistical work. Salary $25 per week. Location New York City. R-2416.

ELECTRICAL ENGINEER now engaged in practical work to assist in dynamo and testing laboratories Monday and Tuesday evenings each week. Technical graduate with a few years of experience and familiar with electrical machinery desired. Position is with an educational institution. Teaching experience unnecessary. Salary $3-3.50 per evening. Location Brooklyn, N. Y. R-2419.

RECENT ELECTRICAL ENGINEERING GRADUATE for sales and export work. Location New York City. R-2420.

EDITOR.—Technically educated man with editorial experience, initiative, and judgment, for position of responsibility with long established high grade engineering periodical. Replies should include the essential facts. R-2424.

ELECTRICAL FOREMAN for Construction Department of Power Company; must be capable of taking entire charge, under supervision of Electrical Superintendent of crew of five or six men, in connection with rebuilding of 18,000 K. W. central station bus structure and switch board. Technical graduate preferred although man with practical experience will be given due consideration. Initial salary $140 per month with opportunity for advancement. Application should contain detail information concerning technical training, past experience, age, nationality, attitude towards question of organized labor and whether or not applicant is user of intoxicating liquors. R-2425.

DRAFTSMAN wanted to lay out construction plans and mechanical equipment for large power houses, apply Westcott & Mapes, Inc., 207 Orange St., New Haven Conn., R-2427.

INSTRUCTORS; All engineers, who are willing to consider teaching positions, are invited to register with the Engineering Societies Employment Bureau. The Bureau has been called upon to fill more positions, varying in grade from Laboratory assistant to heads of department in the various engineering and technical schools of this country, than it has been able to do from among the men now registered. Blanks for the purpose of registration and information regarding the Bureau may be had by addressing W. V. Brown, Manager, 29 West 39th Street.

On the subject of "Payment for Estimating" Engineering Council has appointed three conferees: T. L. Condron, Ralph Modjeski and S. G. Neiler, who are collaborating with an equal number of representatives each of the American Institute of Architects and the Associated General Contractors of America.

As a temporary expedient Engineering Council recently mailed to 50,000 engineers an appeal for funds for carrying on its work. This extraordinary measure was necessitated by present financial conditions resulting from the war. Engineers are expecting much of Council and commending the work which it has done. In order, however, that Council may continue its work for professional welfare and civic service, not less than $45,000 are needed for the year 1920. Of this amount, $30,000, at least, must come from general contributions. To December 16, 550 contributions have been received, totaling $3843. They range from one dollar to $100. each, and average $7.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES FROM NOV. 1st—NOV. 30th, 1919

Unless otherwise specified, books in this list have been presented by the publishers. The Library does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

THE ANALYSIS OF MINERALS AND ORES OF THE RARER ELEMENTS.

For Analytical Chemists, Metallurgists, and Advanced Students. By W. R. Schoeller, and A. R. Powell. Lond., Charles Griffin & Co., Ltd.; Phila., J. B. Lippincott Co. 1919. 239 pp., tables, 9 x 6 in., cloth., 16 shillings. (Gift of J. B. Lippincott Co.)

This is a practical laboratory guide for those interested in the determination of the so-called rare elements, and is the first work, the authors state, in which the complete analysis of the minerals of these elements has received systematic treatment. The methods have been selected from various authorities, supplemented when necessary by methods devised by the authors. Full details are given in each case.

ASBESTOS—From Mine to Finished Product.

N. Y., Asbestos and Mineral Corporation. 1919. 194 pp., 60 pl., 11 x 10 in., cloth.

A collection of sixty photographs of asbestos minerals, mines and manufacturing plants, forming a pictorial presentation of the mining of raw asbestos and its manufacture into finished goods. Brief explanatory notes accompany the illustrations.

HAND-BOOK OF FIRE PROTECTION.

By Everett U. Crosby, Henry A. Fiske and H. Walter Forster. 6th edit. N. Y., D. Van Nostrand Company, 1919. 757 pp., illus., tables, 7 x 5 in., flexible cloth, $4.

This work has long been a standard reference book for insurance engineers and inspectors, in which those methods of fire protection which have crystallized into good practise are collected and presented concisely. The present edition has been enlarged by new chapters and illustrations, and has been carefully revised.

THE OUTLOOK FOR RESEARCH AND INVENTION.

With an Appendix of Problems Awaiting Solution. By Nevil Monroe Hopkins. N. Y., D. Van Nostrand Company, 1919. 241 pp., 1 pl., 6 por., 8 x 5 in., cloth, $2.

The object of this book is to stimulate a more general interest in American research, to indicate its necessity at this time, to explain the educational requirements for research workers and to point out the ways in which such work is done inefficiently at present. Appended to the volume is a list of suggested lines of research.

THE STRATEGY OF MINERALS.

A Study of the Mineral Factor in the World Position of America in War and in Peace.

Edited by George Otis Smith, with an introduction by Franklin K. Lane, N. Y. & Lond., D. Appleton & Co., 1919. 372 pp., 8 x 5 in., ½ cloth, $2.50.

CONTENTS: International Relations and Economic Minerals—The Shipping Crisis—Mineral Fuels—Tendencies of Power Production—Iron and Its Associates—Copper—Lead and Zinc—Minor Metals—Minerals in the Chemical Industries—Other Industrial Minerals—Position of the United States among the Nations—A Case of National Dependence: Germany—A Look Ahead—War-time Control of Minerals.

The part played by minerals in the World War and their share in reconstruction are discussed in this volume by a group of geologists in the Government service. The strategic value of mineral resources of the United States in the larger reorganization of peace is taken up along with the problems of their utilization and conservation.

TRAITÉ DE MÉCANIQUE RATIONNELLE.

By Paul Appell. 4th edit., vol. 1. Statique—Dynamique du Point. Paris. Gauthier-Villars et Cie. 1919, 619 pp., 10 x 7 in., paper, 36 francs.

The treatise of which this book forms the first volume is a comprehensive one, covering the course given for many years in the Faculté des Sciences of Paris. The first volume includes the theory of vectors, statics, and the dynamics of particles. The present edition has been thoroughly revised and references to recent writings on the subject have been added.

No previous knowledge of mechanics is assumed. The work is designed to give a thorough understanding of present knowledge of mechanics to those studying the subject in preparation for an engineering career.

A TREATISE ON GYROSTATICS AND ROTATIONAL MOTION. THEORY AND APPLICATIONS.

By Andrew Gray. Lond., Macmillan & Co., Ltd. 1918. 530 pp., illus., tables, 10 x 7 in., cloth, 42 shillings. (Purchase).

Professor Gray has tried to supply a systematic discussion of gyrostatic action and rotational motion which will be of use both to students of dynamics and to practical men. To many engineers, the gyrostatic action of machinery is more or less of a mystery, while to the student, gyrostatics is an affair of certain formal equations by means of which certain elementary results can be obtained.

In the present work, a large number of gyrostatic problems of actual apparatus are discussed, each being referred to first principles and the solutions derived by steps which can be interpreted at every stage of progress.

PAST SECTION MEETINGS

Atlanta.—November 10, 1919, Chamber of Commerce Hall. Address by Chairman A. M. Schoen on activities and aims of the United Engineering Council. The subject of greatest interest was the proposed draft of a bill by the United Engineers' Council which was designed to regulate the practise of engineering in the United States and Canada.

Boston.—November 12, 1919, Engineers Club. Paper: "Storage Batteries, Their Many Applications and Methods of Operation." Speaker: J. Lester Woodbridge. Attendance 100.

Chicago.—September 30, 1919, Fullerton Hall. Subject: "City Zoning." Speaker: Robert W. Whitton, City Plan Commission, Cleveland, Ohio. This was a joint meeting with the General Committee Technical Societies of Chicago. Attendance 250.

October 21, 1919, Fullerton Hall. Subjects: "Non-Partisan Election of Aldermen, 50 Ward Plan;" "$29,000,000. Bond Issue;" "Relation of the Professional Technical Man to Civic Progress." Speakers: Messrs. Douglas Sutherland, Secretary, Civic Federation; Senator J. J. Barbour; Henry K. Holsman. This was a joint meeting with the General Committee Technical Societies of Chicago. Attendance 250.

October 29, 1919, Fullerton Hall. Subject: "Power Supply and Generation of the Future." Speaker: Dr. C. P. Steinmetz. Attendance 525.

November 24, 1919, Western Society Rooms. Subjects: "Personal Efficiency of the Employee;" "Electrical Power as a Factor in Effecting Economics and Increasing Production;" "Reaction of Labor to Intensive Lighting." Speakers: Messrs Harold Almert, Consulting Engineer; Geo. H. Jones, Power Engineer, Commonwealth Edison Co.; Edwin D. Tillson, Testing Engineer, Commonwealth Edison Co. Attendance 250.

Cleveland.—November 18, 1919, place of meeting Cleveland Engineering Society. Subject: "The Use of Electricity on the Farm." Speaker: Mr. C. W. Emerson, Consulting Engineer, Kewanee Private Utilities Co. The Section was honored by the presence of Mr. P. M. Lincoln, Past-President of the Institute.

Denver.—November 22, 1919, dinner at the Shirley Hotel. After dinner Chairman Evans called the meeting to order and reference was made to the Jones-Reavis Bill S-2232. Resolutions were adopted supporting this Bill. Speaker of the evening was Mr. A. L. Powell, who gave a very interesting lecture on the "Late Developments in Industrial Store and Residence Lighting" which was illustrated by lantern slides. Attendance 36.

Detroit-Ann Arbor.—November 14, 1919, Board of Commerce. Subject: "Synchronous Motor Characteristics." Speaker: Prof. B. F. Bailey of the University of Michigan.

Fort Wayne.—November 20, 1919, G. E. Co. Bldg. 16-2 Mr. J. J. Kline extracted a paper which had been delivered before the British Academy for the Advancement of Science by Mr. Charles A. Parsons, indicating engineering developments which had taken place during and as a result of the war. Attendance 45.

Indianapolis-Lafayette.—November 14, 1919, Chamber of Commerce. Speaker: Mr. B. C. Groh, of New York. Subject: "Modern Problems of the Automatic Telephone Exchange." Attendance 86.

Ithaca.—October 24, 1919, Franklin Hall, Cornell University. Subject: "The Coming Science of Acoustical Engineering." Speaker: Professor V. Karapetoff, of Cornell University. Attendance 115.

Lynn.—November 19, 1919. G. E. Hall. Social meeting. A program of different forms of entertainment was provided and refreshments were served. Attendance 200.

December 3, 1919, G. E. Hall. Subject: "The Development of the Incandescent Lamp and its Manufacture." Speaker: Mr. J. W. Howell, Chief Engineer, Edison Lamp Factories, Harrison, N. J. Attendance 150.

Madison.—November 7, 1919, Engineering Building. Chairman was authorized to appoint a committee to investigate the present status of Water Power Legislation and make a report at next meeting. The report of the Development Committee of the Institute was discussed by Prof. Watson. Attendance 9.

Minnesota.—November 10, 1919, Dunwoody Institute. Dr. C. A. Prosser and Mr. K. W. Kavel outlined the operation of the Dunwoody Institute of Minneapolis, in which 17,000 young men and boys have received training for a trade. An inspection of the building and equipment with the evening classes in session was made. Attendance 50.

Panama.—November 3, 1919, Coco Solo Submarine Base. Meeting consisted of an inspection trip to the U. S. Naval Submarine Base at Coco Solo, Canal Zone, and talks given by Lieut. R. L. Vaughn, Engineer Officer, and Mr. W. L. Hersh, Electrical Engineer of the Panama Canal, who designed the Submarine Storage Battery Charging Station. Attendance 40.

Philadelphia.—December 8, 1919, Engineers Club. Paper: "Automobile Headlight Legislation." Speaker: Mr. Clayton H. Sharp. Discussion was entered into by Messrs. Harold Pender, C. E. Clewell, representatives of Automobile Club, and by Benj. Eynon, Registrar of Motor Vehicles for the State of Pennsylvania. Attendance 100.

Pittsburgh.—November 11, 1919, Chamber of Commerce Auditorium. Paper: "The Design and Application of Electric Propulsion Equipment for Submarines." Speakers: Messrs. D. Hall and L. G. Riley, Engineers, Westinghouse Elec. & Mfg. Co. Attendance 55.

December 9, 1919 Chamber of Commerce Auditorium. Paper: "The Power Indicating and Limiting Apparatus for the Columbia and Coast Divisions of the C. M. & St. P. Railroad Company" by Mr. H. B. Smith, Engineer, Westinghouse Elec. & Mfg. Co. Attendance 80.

Portland.—November 18, 1919, University Club. Paper: "Some War Time Developments in Electrical Communication and Allied Fields" by Dr. F. B. Jewett. Dr. Jewett's talk was illustrated with stereopticon slides and moving pictures. Attendance 125.

Rochester.—December 5, 1919. Address by Mr. Will Brown, of the Electrical Machinery Co., on "How Load Driving Synchronous Motors are Helping the Power Factor Situation." Attendance 37.

San Francisco.—November 24, 1919, Native Sons' Hall. Paper: "Some Wartime Developments in Electrical Communication and Allied Fields" by Dr. F. B. Jewett. Attendance 270.

St. Louis.—November 19, 1919, Engineers Club. Joint meeting with the Associated Engineering Societies of St. Louis. Mr. Otto B. Blackwell, Transmission and Protection Engineer, American Telephone & Telegraph Co., gave an illustrated talk on the Telephone Transmission Circuit. Attendance 108.

December 3, 1919, American Annex Hotel. Election of officers for 1920 as follows: G. A. Waters Chairman, and Stanley Stokes, Secretary-Treasurer. Col. E. J. Spencer Secretary-Treasurer of the St. Louis Electrical Board of Trade gave in a most interesting way his reminiscences of experiences during the early days of electrical development. Short talks of this same nature were given by Messrs. H. H. Humphrey E. J. Pietzcker and H. I. Finch. Attendance 52.

Schenectady.—November 21, 1919, Edison Club Hall. Illustrated lecture by Mr. E. F. W. Alexanderson, Radio Engineer, General Electric Company on "Trans-Oceanic Radio Communication." Attendance 325.

December 5, 1919, Edison Club Hall. Illustrated lecture by Mr. W. L. R. Emmet, Consulting Engineer, General Electric Company on "Electric Ship Propulsion." Mr. Emmet gave a history of the electric drive for ships from the time of its inception to the present. He described in detail the present electric drive as installed in the "New Mexico" "California," etc. Attendance 355.

Seattle.—October 21, 1919, Chamber of Commerce. Mr. Sweat read an interesting paper illustrated by photographs and blue prints, describing the application of electric motor drive to auxiliary equipment on board ships. Attendance 45.

Spokane.—November 14, 1919, Davenport Hotel. Dinner in honor of Dr. F. B. Jewett. Matters affecting local sections were discussed informally. Attendance 15.

November 14, 1919, Davenport Hotel. Meeting of the Associated Engineers of Spokane under the auspices of the local Section of the A. I. E. E. Lecture by Dr. F. B. Jewett on "Some Wartime Developments in Electrical Communication and Allied Fields" illustrated with slides and moving pictures. Attendance 165.

Toronto.—November 21, 1919, Engineers Club. Paper on Electric Welding by Mr. F. K. D'Alton. The different methods of welding in use were enumerated, followed by a short description of the well known chemical elements contained in the various forms of iron and steel which must be taken into account in welding. After touching on gas welding the speaker went very thoroughly into electrical welding, covering both spot and fusion welding. A considerable number of slides were shown. Attendance 66.

Utah.—November 9, 1919, Commercial Club. Paper: "Some Wartime Developments in Electrical Communication and Allied Fields" by Dr. F. B. Jewett. Attendance 109.

November 29, 1919. Commercial Club. Subject: "Modern Illuminating Engineering." Speaker: A. L. Powell. Attendance 30.

PAST BRANCH MEETINGS

University of Arkansas.—November 18, 1919, Engineering Hall. Papers: "The Use of Storage Batteries in Automobile Work" by E. P. O'Neal; "Homer-Roberts Selective and Lock-out Telephone System" by Fred Moore. Attendance 16.

November 25, 1919. Talk by Professor Stetzner on "The Engineer as An Economist"; "European Engineers vs. American Engineers" by Guy Ixby; "The History of the Incandescent Lamp" by Max Ware. Attendance 26.

December 2, 1919, Engineering Hall. Papers: "Electric Motors vs. Gasolene Motors in Street Railway Work" by Wm. Nelson; "Electricity Direct from Fuel" by S. Felsenthal. Attendance 15.

Armour Institute of Technology.—October 7, 1919. Talk by Prof. E. H. Freeman on Benefits and Advantages of being affiliated with the A. I. E. E. Attendance 50.

November 5, 1919. Talks by Prof. E. H. Freeman on "Qualities of the Successful Engineer;" E. C. Lang on "What is Expected of the Coll ge Graduate;" R. Fischell on "Choosing a Vocation after Graduation." Attendance 35.

Brooklyn Polytechnic Institute.—November 21, 1919, Potts Lecture Room. Talk by Mr. Martin C. Hughes, New York Edison Co., on "Report Writing." Refreshments were served. Attendance 35.

University of California.—November 5, 1919. Papers: "Three-Phase Locomotive" by C. W. Robbins, and "Kern River Hydroelectric Plant" by L. F. Boerner. Attendance 30.

Carnegie Institute of Technology.—November 25, 1919, Machinery Hall. Paper: "Mechanical and Electrical Features of the West Penn Power Co's Plant at Springdale, Pa." by Messrs. G. G. Bell, Geo. S. Humphrey and H. W. McRobbie, all of the West Penn Co. Illustrated with lantern slides, photostat cuts and blue prints of plans and work at the new plant. Attendance 48.

University of Cincinnati.—November 4, 1919. Paper by Prof. A. M. Wilson on "The Value of Education and What the World Expects from the Educated Man." Attendance 96.

November 18, 1919, Assembly Room, Engg. Bldg. Talk by Mr. Chas. Britten, of the Hyatt Roller Bearing Co., on Roller Bearings for Electrical and Other Machines. Attendance 67.

November 25, 1919, Engineering Bldg. Talk by Mr. J. A. Brett, General Manager of the Cincinnati office of the Westinghouse Elec. & Mfg. Co., on "What Westinghouse is Doing and What are the Chances for Engineers in their Work." Attendance 79.

Clemson Agricultural College.—October 21, 1919, Electrical Engineering Lecture Room. Paper: "Outdoor Illumination" by Mr. A. F. Holley. Other subjects: Current Events, by M. J. Black, and Life of Edison by R. B. Bratton. Attendance 58.

November 4, 1919, Elec. Engg. Lecture Room. Paper: "Storage Batteries" by H. D. Cordes. Other subjects: Current Events by J. O. Brown and Life of Lord Kelvin by J. R. Clark. Attendance 53.

November 18, 1919, Elec. Engg. Lecture Room. Paper: "Farm Lighting Plants" by J. B. Fitzgerald. Other subjects: Current Events by J. D. Salbey, and Life of Elihu Thompson by W. H. Abernathy. Attendance 67.

December 2, 1919, Elec. Engg. Lecture Room. Paper: "High-Tension Transmission" by C. C. Graves. Other subjects: Current Events by B. C. Cobb and Incandescent Lamp by N. G. Rentz. Attendance 59.

University of Colorado.—December 5, 1919. Talk by Mr. Fred W. Hild, General Manager of the Denver Tramway, on the electric tramway problems. Attendance 69.

Kansas State Agricultural College.—November 6, 1919. Paper: "Residence Lighting" read by D. S. McHugh. Illustrated with slides furnished by National Lamp Works. Attendance 73.

November 13, 1919. An explanation and demonstration of the oscillograph by Prof. C. E. Reid. Attendance 72.

University of Kentucky.—December 4, 1919, Mechanical Hall. Three ten-minute talks—"Military Searchlights and Their Scientific Testing" by J. H. Bailey; "Factory Lighting, A Central Station Problem" by H. P. Boone; "Hydroelectric Plant and Paper Mill at Ocean Falls, B. C." by J. Bromagen. Attendance 20.

Lehigh University.—December 4, 1919, Physics Bldg. Papers: "Wireless Telephone" by J. A. Cadwallader; "Wireless Telephone Experiments" by Prof. S. S. Seyfert. Attendance 98.

University of Maine.—November 8, 1919, Lord Hall. Illustrated lecture on arc welding by Messrs. Libby and Holslag, both of the Electric Arc Welding Co., N. J. Attendance 62.

Massachusetts Institute of Technology.—December 5, 1919. Paper: "Economic Development of Electrical Industry" by B. A. Behrend. Attendance 50.

University of Michigan.—November 6, 1919, Engineering Bldg. Business meeting. Attendance 19.

Michigan Agricultural College.—November 25, 1919. Paper: "The World's Mightiest Electric Locomotive" presented by Prof. M. M. Cory. Illustrated by films "The King of the Rails." Attendance 98.

School of Engineering of Milwaukee.—November 21, 1919. Illustrated talk on Hydroelectric Developments in America by Mr. W. M. White, Chief Engineer of the Allis-Chalmers Co. and President of the Engineers Society of Milwaukee. Attendance 241.

University of Missouri.—November 17, 1919, Engineering Bldg. Paper: "Protective Devices" by T. V. LeBow. Attendance 15.

University of Nebraska.—November 12, 1919, Mech. Eng. Bldg. Subject: "Business Relations of the Engineers." Speakers: Messrs. D. E. Byerley and O. J. Fee. Attendance 42.

University of North Carolina.—November 17, 1919. Papers: "Telegraphie Por le Sol" by C. P. Bolick; "The Use of Radio in Our Anti-Submarine Campaign" by W. F. Alston. Attendance 52.

North Carolina State College.—November 13, 1919, E. E. Class Room. Papers. "The Gas Electric Automobile" by F.

A. Long; "Points about Installation of Motors" by C. E. Rhodes; "A New Wireless" by R. S. Collins. Attendance 21.

November 20, 1919, E. E. Class Room. Papers: "Electricity Applied to the Modern Restaurant" by F. P. Huskin; "Electric Locomotives" by M. L. Matthews. Attendance 18.

December 4, 1919, E. E. Class Room. Talk by Mr. W. M. Gallant on the history of the Westinghouse Co. and the apprenticeship course at East Pittsburgh. Attendance 26.

Ohio Northern University.—November 12, 1919, Dukes Memorial. Papers "The Erie Plant of the General Electric Co." by Mr. A. B. Tourtellot; "Isolated Electric Lighting Plants" by Mr. L. D. Beatty. Attendance 21.

December 10, 1919. Lehr Memorial. The following films were shown: "Railroad Electrification"; "King of the Rails;" "The Potter's Wheel." Attendance 250.

Ohio State University.—November 17, 1919, Robinson Laboratory. Business meeting. Attendance 42.

December 5, 1919, Physics Hall. Paper: "Development and Meaning of Illuminating Engineering" by Mr. S. E. Doane. Attendance 173.

Oregon Agricultural College.—October 21, 1919. Business meeting at which Prof. Dearborn explained the purpose and aims of the Student Branch of the A. I. E. E. Attendance 31.

November 19, 1919. Mr. Fred A. Roehrig elected President. Illustrated talk by Mr. F. N. Waters on "Recent Submarine Development." Attendance 55.

Purdue University.—October 28, 1919, Electrical Building. Talks: "Signal Corps Experiences Overseas" by W. H. Snyder; "The Purdue Radio Station" by N. C. Pearcy. Demonstration of wireless apparatus by R. A. Deller and W. D. Freezer. Attendance 95.

November 18, 1919, Electrical Building. Papers: "Electricity and its Progress" by W. B. Nottingham; "Commercial Watthour Meter Testing" by T. K. Hartley; "Railway Electrifications" by Prof. D. D. Ewing. Attendance 150.

November 24, 1919, Electrical Building. Paper: "Manufacture of High-Tension Insulators" by W. A. Hildebrand, Ohio Brass Co., Mansfield, O. Attendance 80.

Stanford University.—November 25, 1919, Electrical Engg. Bldg. Business meeting. Attendance 9.

Stanford University.—December 8, 1919, Elec. Engg. Bldg. Following officers elected—Chairman Aubrey Smith, Vice-Chairman Raymond Lewelling. Professor Harris J. Ryan addressed the meeting on the history of the A. I. E. E., and of the profession in general in America, giving facts about the organization and progress of the Institute. Attendance 15.

A. & M. College of Texas.—November 10, 1919, E. E. Bldg. Talk by W. M. Denny on "Methods of Protection of Employees." Attendance 78.

December 1, 1919, E. E. Building. Talks: "Arc. Welding" by Sgt. Harding; "Power Plant Operation" by Lieut. Burnheim. Attendance 59.

University of Texas.—November 19, 1919. Organization meeting. Following officers were elected—Chairman W. J. Miller, Secretary and Treasurer Clyde Young. Attendance 27.

University of Virginia.—December 4, 1919, Rouse Physical Laboratory. Paper: "Pyrometers" by Dr. L. G. Hoxton. Attendance 25.

Virginia Polytechnic Institute.—November 24, 1919. Lecture by L. D. Fry on the "Mercuric Arc Rectifier." Attendance 29.

November 10, 1919. Messrs. Ray Smith and A. W. Fairer performed an experiment before the members, illustrating how to change a single-phase current to a three-phase current for use on electric railways. Attendance 28.

December 8, 1919. Lectures by Messrs. R. W. Gaskins and W. R. Dixon on the construction and maintenance of the lead plate storage cell and the Edison alkaline storage cell. Attendance 17.

West Virginia University.—November 10, 1919, Mechanical Hall, Election of officers as follows: President H. J. Walls, Vice-President P. H. Sommer, Secretary M. Wilcoxen, Treasurer L. E. Stone. Attendance 16.

November 14, 1919, Engg. Assembly Room. Papers: "Two Hundred and Twenty Kilovolt Transmission Line" by J. M. Frum; "Alternating-Current Clocks" by H. J. Walls; "Electric Welding" by R. J. Stoker; "Induction Motors" by P. D. McDonald; "Pole and Tower Lines" by J. E. Jolliffe; "Development of Substations" by B. Noyes; "Electric Mine Hoist" by C. R. Bickel; "Review of A.-C. Machine Design" by W. C. Fisher; "Phase Splitters" by P. H. Sommer; "Review of Electrical Review" by R. D. Sheffer; "Review of Electrical Journal" by L. E. Stone. Attendance 35.

Washington University.—November 18, 1919. Chairman Bowles and Dean Langsdorf spoke on the purpose of the Branch and the organization of the national body. Mr. Waters of Wagner Electric Co., St. Louis, gave a very interesting and forceful talk on "The Electrical Engineer in the Manufacturing Industry." Refreshments served. Attendance 43.

University of Washington.—November 4, 1919, Forestry Hall. Paper: "Multiplex Radio Telegraphy and Telephony" by Messrs. E. M. Ryan, R. O. Bach and J. R. Tolmie. Attendance 25.

State College of Washington.—October 10, 1919. Subject: "Modern Artillery Practise." Speaker: Major F. C. Tucker. Attendance 38.

November 21, 1919. Subject: "Advertising" Speaker: Prof. M. K. Snyder. Attendance 30.

Worcester Polytechnic Institute.—November 14, 1919, E. E. Hall. Talks by Harry W. Tenney on "Experiences with the Joseph Campbell Co., Camden, N. J.," and Norman P. Marks on "Experiences in Electrical Drafting with the Scovill Mfg. Co., Waterbury, Conn." Attendance 31.

Yale University.—October 3, 1919. Informal talks by Prof. Chas. F. Scott, Prof. Harold V. Bozell, Prof. Lester W. Morrow, Prof. H. M. Turner, Lieut. Col. Hineman, Signal Corps, U. S. A., and Mr. D. F. Hine. Attendance 54.

October 17, 1919. Subject: "War Work and Engineering Developments, General Electric Company" by Mr. F. C. Pratt. Attendance 170.

October 29, 1919. Subject: "Outline of General Field of Signal Corps Work in France During the War" by Lieut. Col. Sawyer, Signal Corps, U. S. A. Attendance 16.

MEMBERSHIP

Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED DECEMBER 12, 1919

ADSETT, FREDERICK C., Local Manager, Hydro-Electric Power Commission, Trenton, Ont., Canada.

*AIMUTIS, FRANK J., Designing Electrical Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.

ALLEN, L. E., Dist. Manager, Commonwealth Public Service Co., Ozark, Ark.

ARNOLD, HENRY B., Technical Service Dept., Western Electric Co.; res., Y. M. C. A., 23rd St., New York, N. Y.

ASHWORTH, PAUL P., Distribution Engineer, Utah Power & Light Co., Kearns Bldg., Salt Lake City, Utah.

AUBREY, CHARLES A., Electrician, United Illuminating Co.; res., 102 Harral Ave., Bridgeport, Conn.

BARKER, SPRAGUE, Chief Draftsman, Frank Adam Electric Co., St. Louis, Mo.

BARTON, ROY A., Chief Engineer, Portland Flouring Mills Co.; res., 1203 Wilbur St., Portland, Ore.

BOWEN, WILLIAM EARL, Radio Electrician, In Charge of Laboratory, Norfolk Navy Yard, Portsmouth, Va.

BRENNAN, AUSTIN H., Plant Electrician, Submarine Boat Corp.; res., 86 Bleeker St., Newark, N. J.

BROOKE, GEORGE M., Electrician, Rio Grande Public Service Corp., McAllen, Texas.
*BURT, F. R., General Engineering Div., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
CAMPBELL, J. Archibald, 226 West 238th St., New York, N. Y.
CARNEY, JOHN J., Engineering Dept., Bristol Co.; res., 236 Hillside Ave., Waterbury, Conn.
CARPENTER, HENRY H., Electrical Engineer, Blackstone Valley Gas & Electric Co.; res., 48 Maple St., Woonsocket, R. I.
CATHEY, BEN L., Chief Electrician, Detroit Seamless Steel Tubes Co.; res., 190 Allendale Ave., Detroit, Mich.
CLARKSON, WILLIAM B., Engineer, General Electric Co.; res., 109 Woodland Ave., Schenectady, N. Y.
CORBIN, ALFRED G., Foreman & Elec. Inspector, Welding Basin, American International Shipbuilding Corp., Hog Island, Pa.
COX, I. EUGENE, Electrician, National Enameling & Stamping Co. Steel Works Branch, Granite City, Ill.
CRAWFORD, WILLIAM J., Student Engineer, Cutler-Hammer Mfg. Co., 175 16th St., Milwaukee, Wis.
CRIM, LE ROY C., Chief Engineer, Southern N. Y. Power & Railways Corp., Hartwick, N. Y.
DAHLSTROM, FRANK P., Electrician, American Steel & Wire Co.; res., 179 W. Boylston St., Worcester, Mass.
DANVERS, W. K., Electrical Engineer, Oklahoma Railway Co., 213 Terminal Bldg., Oklahoma City, Okla.
DEELWATER, CARL L., Electrical Tester, Diehl Mfg. Co., Elizabeth, N. J.
*DOYLE, HUGH P., Electrical Engineer, International General Electric Co., 23 Water St., Yokohama, Japan.
DURAISWAMY, C. S., Engineer, Doom Dooma Tea Co., Ltd., Hansara Div., Doom Dooma, Assam, India.
ECHEVARRIA, ARTHUR B., Office Head & Electrical Engineer, "Central Vannina", Rio Piedras, Porto Rico.
EDKINS, EARL V., Electrician, Atlantic Refining Co.; res., 5827 Trinity Place, W. Philadelphia, Pa.
FAIREY, ARTHUR R., Chief Inspecting Engineer, Insulating & Winding Depts., The British Westinghouse Co., Trafford Park, Manchester, Eng.
FARRELL, CHRISTOPHER C., Asst. Electrical Engineering, American Railways Co.; res., 3808 Spring Garden St., Philadelphia, Pa.
FREEMAN, WILLIAM G., Engineering Dept., American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
GARDNER, HARTLEY B., Instructor of Electrical Engineering, Mass. Institute of Technology, Cambridge, Mass.
GARDNER, LELAND A., Engineering Dept., Bijur Motor Appliance Co., Hoboken, N. J.
GATLAND, H. CHARLES, Elec. Engineer, Wairua Power Station, Titoka P. O., Whangarei, Auckland, N. Z.
GELLION, FREDERICK JOHNSON, Engineer & Manager, Electric Lighting Co. Ltd., Macao, So. China.
GINOCCHIO, JAMES A., Electrical Draughtsman, Charles E. Knox Associates, 101 Park Ave., New York, N. Y.
GLEASON, JOHN C., Operating Power Plant Engineer, Germain & Boyd Lumber Co., Atlanta, La.
GOODRICH, CHAUNCEY M., Designing Engineer, The Canadian Bridge Co., Ltd., Walkerville, Ont.
GRACE, IAN WALTER, Elec. Engineer, Martinborough Town Board, Martinborough, Wairarapa, N. Z.
*GRAM, JOHN IRWIN, Asst. Meter Engineer, Ontario Power Co.; res., 43 Main St., Niagara Falls, Ontario.
HARRIS, FRED R., Chief Engineer, Michigan Public Utilities Commission, Lansing, Mich.
HARTVIG, C. E., Signal Supervisor, C. R. I. & P., R. R., 31st. Station, Rock Island, Ill.
HELFRICH, F. A., Electrical Supervisor, Baltimore & Ohio Railroad; res., 1206 Longwood St., Baltimore, Md.
HEYMAN, MORRIS, 1887 Madison Ave., New York, N. Y.
HOFFMAN, ALFRED G., Testing Dept., General Electric Co.; res., 710 South Ave., Schenectady, N. Y.
HUNT, CHARLES M., Sales Engineer, Roller-Smith Co., 233 Broadway, New York, N. Y.
HUNTER, HOWARD V., Engineer, Dept. of Development & Research, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
HUTCHINGS, JOHN MARVIN, Student Engineer, The Emerson Electric Mfg. Co., 2032 Washington Ave., St. Louis, Mo.
*IDAIL, MURRAY J., Electrical Engineer, with F. R. Weller, 408 Hibbs Bldg., Washington, D. C.
JONES, J. W., 1st Shift Engineer, Wairua Falls Power House, Titoki, Whangarei, Auckland, N. Z.
KAWAMATA, TAKASHI, Student, Cornell University, res.; 112 Ferris Place, Ithaca, N. Y.
KELLY, JAMES F., Plant Engineer, Public Service Electric Co., 80 Park Place, Newark, N. J.
KELLY, PATRICK, Commercial Engineer, International General Electric Co., Schenectady, N. Y.
KENT, PIERCE J., Chief System Operator, Edison Electric Illuminating Co., S. Boston; res., 17 Morrill St., Dorchester, Mass.
LAGRANGE, DANIEL E. H., Directeur, de la Firme, La Soudure Electrique Autogene, rue de la Pepiniere, N°18, Bruxelles, Belgium.
*LAWRENCE, MERRITT T., Testing Dept., General Electric Co.; res., 205 Seward Place, Schenectady, N. Y.
MAC DOUGALL, CHARLES G., Sales Engineer, Canadian General Electric Co., King & Simcoe Sts., Toronto, Ont.
MAC FADDEN, Samuel P., Asst. to Railway Supt., Eastern Texas Electric Co., Beaumont, Texas.
MAHLMEISTER, EUGENE J., Jr., Inspector, Philadelphia Electric Co., 1000 Chestnut St., Philadelphia, Pa.
MARGETTS, WILLIAM LESTER, Asst. Electrical Engineer, Havana Central R. R. Co., Havana, Cuba.
*MARICH, WILLIAM D., Foreman, Elec. Testing Dept., American International Shipbuilding Corp., Hog Island, Pa.
MASUMI, KEIZO, Engineer, Yasukawa Electric Works, Kurosakimachi, Fukuokaken, Japan.
MATTHEWS, CAREY T., Manager, Town of Lillington, Lillington, N. C.
MAYNARD, ALEXANDER R., Sales Manager, Western Electric Co., Inc., Detroit, Mich.
McCONNAUGHEY, EUGENE C., Division Equipment Inspector, Western Union Tel. Co., 800 Transportation Bldg., Atlanta, Ga.
*McELROY, DAVID W., Engineer, Railway & Lighting Dept., General Electric Co., of Cuba, Havana, Cuba.
*MILLER, MERRITT B., Student, Purdue University, 500 N. Salisbury St., W. Lafayette, Ind.
*MILLER, W. J., Adjunct Prof. of Elec. Engineering, Univ. of Texas; res., 2620 Wichita St., Austin, Texas.
MOYER, H. WAYNE, Electrical Tester, Philadelphia Electric Co.; res., 4539 N. 17th St., Philadelphia, Pa.
MURRAY, LOUIS E., 1st Operator, Mt. Whitney Substation, So. California Edison Co., Porterville, Cal.
NEWBURY, ROBERT C., Engineer, Denver Gas & Elec. Light Co., Denver, Colo.
*NEWLANDER, RALPH A., Division Traffic Inspector, Western Union Tel. Co., 111 W. Jackson Blvd., Chicago, Ill.
NEWMARK, MORRIS, Supt. & Estimator, for David Dunn, 1136 Girard Ave., Philadelphia, Pa.
OIKAWA, HOTORI, Prof. of Elec. Engineering, Port Arthur Technical Institute, Port Arthur, Japan.
PAPAMARCO, DEMETRI, Stationary Engineer; res., 356 Clifton Place, Brooklyn, N. Y.
PARDEY, GILBERT R., Service Dept., Westinghouse Electric & Mfg. Co.; res., 39 St. Botolph St., Boston, Mass.
PATTERSON, JAMES F., Telephone Engineer, Northern Electric Co.; res., 7 Essex Ave., Montreal, Que.
PITTENGER, PAUL N., Resident Supervising Engineer, Lockwood, Greene & Co., Healy Bldg., Atlanta, Gal
RACAZA, VICENTE A., Electrical Engineer, Ormoc Electric Light Co., Ormoc, Leyte; res., 92 Juan Luna St., Cebu, Cebu, Philippine Islands.
*RIES, CASPER F., Tester, The Detroit Edison Co.; res., 510 Pasadena Ave., Detroit, Mich.
*ROYDEN, GEORGE T., Radio Laboratorian, Mare Island Navy Yard, 311 Ellsworth Ave., San Mateo, Cal.
RYAN, JOHN THOMAS, Industrial Engineer, Century Electric Co., 818 Bessmer Bldg., Pittsburgh, Pa.
SAYRE, EDGAR W., Draftsman, Wagner Electric Mfg. Co., 2018 Locust St., St. Louis Mo.
SCHACHT, ELMER C., 312 Decatur St., Sandusky, Ohio.
SCHILDKNICHT, ALBERT E., Asst. Instructor, Bliss Electrical School, Takoma Park, D. C.
SCHMIDT, JOHN FREDERICK, Foreman, Plant Maintenance, Federal Shipbuilding Co., Kearny, N. J.
SCHOENBERGER, JULIUS E., Electrical Draftsman, Charles E. Knox Associates, 101 Park Ave., New York, N. Y.
SCHWENDLER, RICHARD H., Aeronautical Engineer, 53 East 54th St., New York, N. Y.
SCOTT, WALTER, 2nd Engineer, Philadelphia Electric Co., Philadelphia; res., Lodges Lane, Cynwyd, Pa.
SEEM, FRED B., Supt. Telephone & Telegraph Empire Companies, Masonic Bldg., Bartlesville, Okla.
SEKIZAWA, SANKICHI, Engineer, Yasukawa Electric Works, Kurosakimachi, Fukuokaken, Japan.
SHAHAN, J. HUBERT, Test Dept., Diehl Mfg. Co.; res., 217 Inslee Place, Elizabeth, N. J.
SHAW, ALEXANDER HUNTLY, Operator, Surf Inlet Power Co., Surf Inlet, B. C.
*SLOAN, DAVID McCURTIE, Statistician, Carolina Power & Light Co., Raleigh, N. C.
SPLITSTONE, EDWARD L., Commercial Engineer, The Emerson Electric Mfg. Co., St. Louis; res., 114 Bompart Ave., Webster Groves, Mo.
STAEHLE, DANIEL, JR., Instructor, Electrical Dept., David Rankin Jr., School of Mech. Trades, St. Louis, Mo.
*STELLE, JOSEPH G., Asst. Switchboard Operator, New York Edison Co., New York; res., 53 Parcell St., Elmhurst, N. Y.

STEVENS, ROGER B., Supervisor, Div. of Plant Appraisal, American Sugar Refining Co.; res., 1933 S. Gayoso St., New Orleans, La.

WHITE, JAMES M., Laboratory Asst., Northern Electric Co. Ltd., 121 Shearer St., Montreal, Quebec.
WHITEFIELD, WILLIAM I., Asst. Supt., L. & P. Dept., Roanoke Railway & Elec. Co., Roanoke, Va.
WILLIAMS, EDWIN T., Electrical Inspector, N. Y. C. R. R. Co., Grand Central Terminal, New York, N. Y.
WILLSON, ABNER R., Apex, Bingham Canyon, Utah.
WILSTAM, ALFRED, Electrical Engineer, So. California Edison Co., Edison Bldg., 3rd & Broadway, Los Angeles, Cal.
*WRIGHT, RALPH H., General Engineering Div., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
Total 111
*Former enrolled student.

ASSOCIATE RE-ELECTED DECEMBER 12, 1919

BURCHER, REGINALD H., Outside Plant Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

MEMBERS ELECTED DECEMBER 12, 1919

BUCKLEY, OLIVER E., Research Engineer, Western Electric Co. Inc., 463 West St., New York, N. Y.
CABLE, MATTHEW, Acting Gen. Manager & Engineer, Tramway Department, Harris St., Wellington, N. Z.
CHARLTON, ALEXANDER MARK, Lieut-Comdr., U. S. N., Bureau of Steam Engg., Navy Dept., Washington, D. C.
HALL, EVERETT D., Division Head, Engineering Dept., Western Electric Co., 463 West St., New York, N. Y.
KELLER, LEO, Systems Engineer, Western Electric Co., 463 West St., New York, N. Y.
NIMMO, HENRY, Dist. Education Officer in Army, 52 The Common, Woolwich, London, S. E., 18, Eng.
PARKER, FREDERICK THOMAS, Major, Chief Elec. & Mech. Engr., Special Constr. Directorate, Civil Engineer-in-Chief's Dept., Admiralty, London, S. W., England.

Transferred to Grade of Member December 12, 1919

BROWN, CARROL G., Professor of Electrical Engineering, School of Engineering, Milwaukee, Wis.
FERGUSON, HOWARD F., District Engineer, Republic Engineers, Inc., Youngstown, O.
SCRIVENER, ROBERT M., District Manager, Alfred Collyer & Co., Toronto, Ont.
WEISS, FERNAND C., Superintendent of Construction, Alabama Power Co., Birmingham, Ala.
WHITING, DONALD F., Electrical Engineer, Special Research Division, Western Electric Co., New York, N. Y.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at its regular monthly meeting, held on December 8, 1919, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

TO GRADE OF FELLOW

BALL, JOHN D., Vice-President and Dean, School of Engineering of Milwaukee, Milwaukee, Wis.
GREEN, CHARLES M., Research Laboratory, General Electric Co., Lynn, Mass.

TO GRADE OF MEMBER

BURCHER, REGINALD H., Outside Plant Engineer, American Tel. & Tel. Co., New York, N. Y.
DANE, LOUIS P., Asst. Chief Engineer, Railway & Industrial Engineering Co., Greensburg, Pa.
DAVIDSON, WARD F., Instructor in Electrical Engineering, University of Michigan, Ann Arbor, Mich.
HARDY, NORMAN G., Chief Mechanical and Electrical Engineer, The Arizona Copper Co. Ltd., Clifton, Ariz.
HOGAN, JOHN V. L., Manager, International Radio Telegraph Co., New York, N. Y.
LENNARD, WILLIAM H., Electrical Supt., The Haughton Elevator & Machine Co., Toledo, O.
OAKES, CHARLES E., Associate Electrical Engineer, Bureau of Standards, Washington, D. C.
PIERCE, GUY C., Vice-President and General Manager, Northwestern Electric Co., Portland, Ore.
SIMPSON, FRANK, Manager St. Louis District, Pittsburgh Transformer Co., St. Louis, Mo.
WEIGHTMAN, HUGH E., Director, Research Division, Atlas Electric Devices Co., Chicago, Ill.
WURTS, THOMAS C., Heavy Traction Section, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before January 31, 1920.

Abbott, Donald A., Ft. Wayne, Indiana.
Anderson, William F., Toledo, Ohio.
Anderton, Thomas R., Dover, New Hampshire.
Appuhn, William E. F., Brooklyn, N. Y.
Arnold, Ellis J., Ann Arbor, Michigan.
Aslanides, D. J., E. Pittsburgh, Pennsylvania.
Bach, Roy O., Seattle, Washington.
Bacon, Marion F., Ft. Wayne, Indiana.
Baker, Douglas B., New York, New York.
Baker, George C., Brooklyn, N. Y.
Baker, Henry S., Niagara Falls, Ontario.
Ballard, Harold L., Ann Arbor, Michigan.
Ballew, Walter W., Atlanta, Georgia.
Beedenbender, Harry L., Yonkers, New York.
Benjamin, Abraham S., Chicago, Illinois.
Bennett, Rolland H., San Francisco, California.
Bewlay, Henry F., (Member), Mansfield, Ohio.
Bicak, Edward T., (Member), New York, N. Y.
Bolton, John I. N., Toronto, Ontario.
Boyere, Emery E., Green Bay, Wisconsin.
Brinkman, Erwin E., Milwaukee, Wisconsin.
Browning, Hardy P., Fort Sam Houston, Texas.
Brunson, Lawrence W., Ann Arbor, Michigan.
Burger, Edward J., San Bernardino, California.
Billstein, Arthur E. F., Philadelphia, Pennsylvania.
Birch, Leland W., Hartsville, South Carolina.
Blatchley, Henry, New Haven, Connecticut.
Blunk, Adolf, Durham, North Carolina.
Bond, Thomas D., Boston, Massachusetts.
Brackett, William H., Montreal, Quebec.
Brown, Henry S., Ottawa, Ontario.
Brunson, Lawrence W., Ann Arbor, Michigan.
Cappon, Marvin T., Montour Falls, New York.
Church, Leroy, Redbank, New Jersey
Colburn, Wellen H., Lynn, Massachusetts.
Cowgill, Lester B., Seattle, Washington.
Cox, Carl C., Fort Worth, Texas.
Dart, Harry F., Scranton, Pennsylvania.
Dominick, William G., Pittsfield, Massachusetts.
Eberhardt, Wallace W., Birmingham, Alabama.
Eslick, Everett, E. Pittsburgh, Pennsylvania.
Ellsworth, G. L., Colton, California.
Fairman, James F., Ann Arbor, Michigan.
Fonstermacher, Charles N., New York, N. Y.
Fowler, Clarence B., New York, New York.
Friis, H. Trap, New York, New York.
Fronmuller, Theodor C., San Francisco, California.
Gadberry, Joseph L., Dallas, Texas.
Galsteren, Andrew, San Francisco, California.
Gefke, Jerome H., Milwaukee, Wisconsin.
Gemmill, Melvin E., Sparrows Point, Maryland.
Gittings, William N., Schenectady, New York.
Glasser, Charles E., Schenectady, New York.
Goldhammer, Charles J., Elkhart Lake, Wisconsin.
Grafing, Fred H., Brooklyn, New York.
Halls, Robert A., Philadelphia, Pennsylvania.
Halporn, Arnold D., Philadelphia, Pennsylvania.
Harbert, William H., Hailey, Idaho.
Hasegawa, Keizo, New York, New York.
Havens, Charles B., Denver, Colorado.
Hempsey, Charles E., New York, New York.
Hefstetter, Carl F., St. Louis, Missouri.
Henderson, Charles W., Syracuse, N. Y.
Hoffman, Edward L., Chicago, Illinois.
Hotchkiss, Fred W., Minneapolis, Minnesota.
Hughes, Calvin T., Waterbury, Connecticut.
Hughes, Martin C., New York, New York.

Hulatt, H., Montreal, Quebec.
Hyatt, Sidney M., Milwaukee, Wisconsin.
Johnson, Lewis H., (Member), New York, N. Y.
Juhnke, Paul B., (Member), San Francisco, Cal.
Kaufman, George A., Munhall, Pennsylvania.
Keesling, Hector, San Francisco, California.
Klee, William A., (Member), St. Louis, Missouri.
Kleist, Walter A., Seattle, Washington.
Klumbach, Hampton R., Syracuse, New York.
Koonsman, Harold D., Detroit, Michigan.
Kurtz, Edwin B., Ames, Iowa.
Lankton, William W., Detroit, Michigan.
Lubeke, Charles M., Seattle, Washington.
Lundell, Carl H., (Member), Portland, Oregon.
MacAlister, Alexander G., Philadelphia, Pennsylvania.
Magee, James F., Allentown, Pennsylvania.
Maggi, Guy J., New York, New York.
Mathes, Robert C., New York, New York.
Merkel, Oswald H., Ludlow, Massachusetts.
Meyer, Charles C., Philadelphia, Pennsylvania.
Miller, Claude A., Tacoma, Washington.
Moore, Raymond P., Buffalo, New York.
Moser, Harry W., Hog Island, Pennsylvania.
Muellman, Joseph P., Chicago, Illinois.
McCartin, James W., Philadelphia, Pennsylvania.
McClure, Edward W., Preston, Idaho.
McDowell, Hamilton E., Allentown, Pennsylvania.
McElhose, Irving H., Utica, New York.
McKibbin, Robert H., Phoenix, Arizona.
Nairn, John M., Pittsburgh, Pennsylvania.
Nelson, E. C., Schenectady, New York.
Nethercut, Donald W., Mansfield, Ohio.
Norman, Earl E., Atlanta, Georgia.
Novak, Frank L., New York, New York.
Oehlschager, William A., Trenton, New Jersey.
Pelaez, Ernesto C., Cleveland, Ohio.
Poe, Charles R., New York, New York.
Pomeroy, William C., Berkeley, California.
Porges, Edward D., Indianapolis, Indiana.
Porter, H. L., Cleveland, Ohio.
Predock, Norvill H., St. Louis, Missouri.
Ross, Russell H., Minneapolis, Minnesota.
Rowand, Alfred M., Ada, Ohio.
Schlenk, Hugo, Jr., Minneapolis, Minnesota.
Schwartz, Emil E., New York, New York.
Sechrist, Gilbert H., Ruston, Louisiana.
Shaw, Harold N., Milwaukee, Wisconsin.
Smith, Winfred W., Palmerton, Pennsylvania.
Smithson, Earl W., New York, N. Y.
Smythies, Reginald E., Toronto, Ontario.
Spoon, Philip, Jackson, Michigan.
Sporn, Max E., New York, N. Y.
Stacy, John D., Pittsfield, Massachusetts.
Stanford, Leland H., Fort Sam Houston, Texas.
Stevens, John C., (Member), Portland, Oregon.
Storm, Hans O., Stanford University, California
Stuart, Virgil N., New York, New York.
Sudderth, D. Glenn, Jr., Atlanta, Georgia.
Sumner, William A., E. Pittsburgh, Pennsylvania.
Swisher, Arthur W., Hog Island, Pennsylvania.
Thomas, Milton A., Waterbury, Connecticut.
Tranick, Henry P., Schenectady, New York.
Utley, Romeyn L., Newark, New Jersey.
Walther, Harry L., (Member), Medford, Oregon.
Warner, Harry O., Washington, D. C.
Wehle, Paul G., New York, New York.
West, Harry R., Philadelphia, Pennsylvania.
Whiting, Arthur C., New York, New York.
Whittle, Horace, New York, New York.
Withers, Francis P., Chicago, Illinois.
Whipperman, Frederic B., St. Louis, Missouri.
Whitcomb, Arthur J., Chicago, Illinois.
Yost, Charles H., Erie, Pennsylvania.
Young, Levi F., Kansas City, Missouri.
Zeiger, Louis B., Brooklyn, New York.
Zippler, William N., Philadelphia, Pennsylvania.
Total 143.

Foreign

Day, Bernhard F. J., London, England.
Deane, Tsung Y., Shanghai, China.
Ekdahl, Edwin A., Shanghai, China
Ewing, Sydney E. T., (Member), Johannesburg, S. Africa.
Henderson, Horace W. W., (Member), London, Eng.
Houston, Robert, Leeton, N. S. Wales, Australia.
Leonida, Dimitrie, (Member), Bucharest, Roumania.
Reese, Clarence B., Rancagua, Chile, S. A.
Total 8.

STUDENTS ENROLLED

DECEMBER 12, 1919

10671 Ochoa, George V., University of Illinois
10672 Schmitt, Arthur E., University of Illinois
10673 Pinckard, Frank E., University of Cincinnati
10674 Kepler, Lionel J., University of Cincinnati
10675 Hannum, Dane M., University of Cincinnati
10676 Huss, Frank W., Jr., University of Cincinnati
10677 Meyer, Charles S., University of Cincinnati
10678 Kemper, W. F., School of Engineering of Milwaukee
10679 Reading, J. E., School of Engineering of Milwaukee
10680 Huebner, G. K., School of Engineering of Milwaukee
10681 Dettwiller, C. J., School of Engineering of Milwaukee
10682 Dodds, F. C., School of Engineering of Milwaukee
10683 Bach, D. F., School of Engineering of Milwaukee
10684 Van Susteren, P. J., School of Engineering of Milwaukee
10685 Woellert, L. N., School of Engineering of Milwaukee
10686 Stott, J. E., School of Engineering of Milwaukee
10687 Kirkland, J. S., School of Engineering of Milwaukee
10688 Aitken, R. K., School of Engineering of Milwaukee
10689 Kratzer, J. B., School of Engineering of Milwaukee
10690 Fitzimmons, R. R., School of Engineering of Milwaukee
10691 Ackerman, A. J., School of Engineering of Milwaukee
10692 Schumacker, O. E., School of Engineering of Milwaukee
10693 Shinkle, J. B., School of Engineering of Milwaukee
10694 Little, E. G., School of Engineering of Milwaukee
10695 Barenscher, P. J., School of Engineering of Milwaukee
10696 Renner, F. J., School of Engineering of Milwaukee
10697 Illing, I. L., School of Engineering of Milwaukee
10698 Ewald, L. J., School of Engineering of Milwaukee
10699 Hogue, B. E., School of Engineering of Milwaukee
10700 Adams, L. W., School of Engineering of Milwaukee
10701 Greenman, C. W., School of Engineering of Milwaukee
10702 Ericsson, F. A., School of Engineering of Milwaukee

A. M. SCHOEN, L. R. JORGENSEN, C. E. SKINNER, N. A. CARLE, JOHN B. FISKEN, WILLS MACLACHLAN

MANAGERS.

(Terms expire July 31, 1920) CHARLES S. RUFFNER, CHARLES ROBBINS, E. H. MARTINDALE

(Terms Expire July 31, 1921) WALTER A. HALL, WILLIAM A. DEL MAR, WILFRED SYKES

(Terms Expire July 31, 1922) WALTER I. SLICHTER, G. FACCIOLI, FRANK D. NEWBURY

(Terms Expire July 31, 1923) L. E. IMLAY, F. F. FOWLE, L. F. MOREHOUSE

TREASURER — **SECRETARY**

(Term expires July 31, 1920)

GEORGE A. HAMILTON — F. L. HUTCHINSON

HONORARY SECRETARY
RALPH W. POPE

DIRECTOR OF THE LIBRARY
HARRISON W. CRAVER

GENERAL COUNSEL

PARKER and AARON,
52 Broadway, New York.

PAST PRESIDENTS—1884-1918

*Norvin Green, 1884-5-6.
*Franklin L. Pope, 1886-7.
T. Commerford Martin, 1887-8.
Edward Weston, 1888-9.
Elihu Thomson, 1889-90.
*William A. Anthony, 1890-91.
Alexander Graham Bell, 1891-2.
Frank Julian Sprague, 1892-3.
*Edwin J. Houston, 1893-4-5.
*Louis Duncan, 1895-6-7.
Francis Bacon Crocker, 1897-8.
A. E. Kennelly, 1898-1900.
Carl Hering, 1900-1.
Charles P. Steinmetz, 1901-2.
Charles F. Scott, 1902-3.
Bion J. Arnold, 1903-4.
John W. Lieb, 1904-5.
Schuyler Skaats Wheeler, 1905-6.
Samuel Sheldon, 1906-7.
*Henry G. Stott, 1907-8.
Louis A. Ferguson, 1908-9.
Lewis B. Stillwell, 1909-10.
Dugald C. Jackson, 1910-11.
Gano Dunn, 1911-12.
Ralph D. Mershon, 1912-13.
C. O. Mailloux, 1913-14.
Paul M. Lincoln, 1914-15.
John J. Carty, 1915-16.
H. W. Buck, 1916-17.
E. W. Rice, Jr., 1917-18.
Comfort A. Adams, 1918-19.

*Deceased.

A. I. E. E., COMMITTEES

GENERAL STANDING COMMITTEES

EXECUTIVE COMMITTEE

Calvert Townley, Chairman, 165 Broadway, New York.
N. A. Carle, W. A. Hall, George A. Hamilton, L. F. Morehouse, W. I. Slichter, C. E. Skinner.

FINANCE COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
W. A. Hall, L. F. Morehouse.

MEETINGS AND PAPERS COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
L. W. Chubb, E. E. F. Creighton, John H. Finney, L. R. Jorgensen.
Chairman of Committee on Technical Activities, the chairmen of all technical committees, and the chairmen of all Sections.

PUBLICATION COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
N. A. Carle, Wm. A. Del Mar, F. L. Hutchinson, Harold Pender

BOARD OF EXAMINERS

F. L. Rhodes, Chairman, 195 Broadway, New York.
Murray C. Beebe, H. N. Latey, Wm. S. Murray, H. H. Norris, E. M. Sawtelle, Clayton H. Sharp, Wilfred Sykes, H. S. Wynkoop.

SECTIONS COMMITTEE

Walter A. Hall, Chairman, General Electric Co., West Lynn, Mass.
C. Francis Harding, Vice-Chairman, Purdue University, Lafayette, Ind.
F. B. Jewett, H. A. Pratt, J. Lloyd Wayne, 3rd,
and the chairmen of all Institute Sections *ex-officio*.

COMMITTEE ON STUDENT BRANCHES

C. Francis Harding, Chairman, Purdue University, Lafayette, Ind.
Alexander M. Gray, A. C. Lanier, J. C. Parker, Charles F. Scott.

MEMBERSHIP COMMITTEE

R. W. Krass, Chairman, W. E. & M. Co., 165 Broadway, New York City.
Wills Maclachlan, S. C. Medbery, Jr., G. S. Rose, G. E. Stoltz,
and the Chairmen of all Membership Committees of Sections.

PUBLIC POLICY COMMITTEE

H. W. Buck, Chairman, 49 Wall St., New York.
C. A. Adams, N. A. Carle, John W. Lieb, A. C. Marshall, Wm. McClellan, C. E. Skinner.

LAW COMMITTEE

Samuel Sheldon, Chairman, 198½ Schermerhorn St., Brooklyn, N. Y.
John H. Finney, F. B. Jewett, Charles Robbins, D. B. Rushmore, Charles A. Terry.

HEADQUARTERS COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
William A. Del Mar, F. L. Hutchinson.

U. S. NATIONAL COMMITTEE OF INTERNATIONAL ELECTROTECHNICAL COMMISSION

C. O. Mailloux, President, 20 Nassau St., New York.
F. B. Crocker, Vice-President,
A. E. Kennelly, Secretary, Harvard University, Cambridge, Mass.
Comfort A. Adams, B. A. Behrend, James Burke, John J. Carty, L. W. Chubb, W. A. Del Mar, Gano Dunn, H. W. Fisher, H. M. Hobart, Dugald C. Jackson, B. G. Lamme, W. S. Moody, Charles Robbins, E. B. Rosa, David B. Rushmore, Charles F. Scott, Clayton H. Sharp, C. E. Skinner, S. W. Stratton, Elihu Thomson, R. B. Williamson.

COMMITTEE ON SAFETY CODES

Farley Osgood, Chairman, 80 Park Place, Newark, N. J.
J. C. Forsyth, H. B. Gear, H. O. Lacount, Johnston Livingston, M. G. Lloyd, R. W. E. Moore, Henry N. Muller, H. R. Sargent, G. A. Sawin, A. M. Schoen, George F. Sever, H. S. Warren.

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT

George F. Sever, 4 Divinity Ave., Cambridge, Mass.
C. A. Adams, A. H. Babcock, L. B. Stillwell, Schuyler Skaats Wheeler.

BOARD'S COMMITTEE ON TECHNICAL ACTIVITIES

Wilfred Sykes, Chairman, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
G. Faccioli, W. I. Slichter.

STANDARDS COMMITTEE

L. T. Robinson, Chairman, General Electric Co., Schenectady, N. Y.
E. J. Cheney, Secretary, Public Service Commission, Albany, N. Y.
P. G. Agnew, G. A. Anderegg, Frederick Bedell, L. F. Blume, James Burke, G. A. Burnham, P. H. Chase, H. H. Clark, F. P. Cox, E. B. Craft, W. A. Del Mar, F. M. Farmer, H. W. Fisher, F. C. Hanker, H. M. Hobart, H. H. Humphrey, H. D. James, P. Junkersfeld, A. E. Kennelly, G. L. Knight, R. W. Krass, C. O. Mailloux, C. S. McDowell, W. L. Merrill, Taliaferro Milton, L. F. Morehouse, F. D. Newbury, H. S. Osborne, S. G. Rhodes, Charles Robbins, R. F. Schuchardt, C. E. Skinner, A. B. Smith, John B. Taylor, A. H. Timmerman, W. K. Vanderpoel, R. B. Williamson.

EDISON MEDAL COMMITTEE

Appointed by the President for terms of five years

Term expires July 31, 1920.
Carl Hering, Chairman, Harris J. Ryan, Robert Lindsay.
Term expires July 31, 1921.
W. C. L. Eglin, Bancroft Gherardi, E. W. Rice, Jr.
Term expires July 31, 1922.
Comfort A. Adams, L. A. Ferguson, S W Stratton.
Term expires July 31, 1923.
Frederick Bedell, L. T. Robinson, Calvert Townley.
Term expires July 31, 1924.
E. D. Adams, H. H. Barnes, B. G. Lamme.

Elected by the Board of Directors from its own membership for terms of two years.

Term expires July 31, 1920.
Charles Robbins, C. E. Skinner, W. I. Slichter.
Term expires July 31, 1921.
G. Faccioli, W. A. Hall, Wilfred Sykes.

Ex-Officio

Calvert Townley, President, George A. Hamilton, Treasurer, F. L. Hutchinson, Secretary.

SPECIAL COMMITTEE

COMMITTEE ON DEVELOPMENT

Charles F. Scott, Chairman, Sheffield Scientific School, Yale University, New Haven, Conn.

F. F. Brand, Pittsfield, Mass. H. E. Bussey, Atlanta, Ga.
J. C. Clark, Stanford University, Cal. Clem A. Copeland, Los Angeles, Cal.
Ira M. Cushing, Boston, Mass. R. H. Dalgleish, Washington, D. C.
W. A. Del Mar, New York, N. Y. F. G. Dustin, Minneapolis, Minn.
H. W. Eales, St. Louis, Mo. H. S. Evans, Boulder, Colo.
F. R. Ewart, Toronto, Ont. Baxter R. Grier, Gatun, C. Z.
W. A. Hall, W. Lynn, Mass. John Harisberger, Seattle, Wash.
W. F. James, Philadelphia, Pa. V. Karapetoff, Ithaca, N. Y.
Leslie Killam, Milwaukee, Wis. J. J. Kline, Fort Wayne, Ind.
P. M. Lincoln, Pittsburgh, Pa. Chas. A. Lund, Spokane, Wash.
A. S. MacDowell, Rochester, N. Y. John C. Parker, Ann Arbor, Mich.
H. T. Plumb, Salt Lake City, Utah. L. T. Robinson, Schenectady, N. Y.
A. M. Schoen, Atlanta, Ga. R. F. Schuchardt, Chicago, Ill.
C. H. Schum, Erie, Pa. W. D. Scott, Portland, Ore.
Samuel Sheldon, Brooklyn, N. Y. G. E. Snider, Toledo, O.
N. W. Storer, Pittsburgh, Pa. L. E. Underwood, W. Lynn, Mass.
H. L. Wallau, Cleveland, O. J. W. Watson, Madison, Wis.
J. Lloyd Wayne, Indianapolis, Ind. J. B. Whitehead, Baltimore, Md.

TECHNICAL COMMITTEES

ECONOMICS OF ELECTRIC SERVICE

C. S. Ruffner, Chairman, The North American Company, 30 Broad Street, New York.
H. V. Bozell, John B. Fisken, W. S. Gorsuch,
L. G. Ireland, A. H. Kruesi, J. F. Meyer,
S. G. Rhodes, Allard Smith, E. H. Sniffen,
P. B. Yates.

EDUCATIONAL

J. C. Parker, Chairman, 274 New Engineering Bldg., Ann Arbor, Mich.
C. R. Dooley, F. F. Fowle, Charles S. Howe,
C. E. Magnusson, E. B. Merriam, L. F. Morehouse,
G. H. Pfeiff, H. W. Price, R. F. Schuchardt,
W. I. Slichter, William R. Work.

ELECTRICAL MACHINERY

B. A. Behrend, Chairman, 200 Devonshire St., Boston, Mass.
James Burke, Alexander Churchward, A. M. Dudley,
C. E. Eveleth, G. Faccioli, B. G. Lamme,
A. C. Lanier, R. B. Williamson.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

F. A. J. FitzGerald, Chairman, FitzGerald Laboratories, Niagara Falls, N. Y.
F. F. Ambuhl, E. R. Berry, Joseph L. Dixon,
I. R. Edmands, L. E. Imlay, F. A. Lidbury,
W. R. Whitney, J. L. Yardley.

ELECTROPHYSICS

F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.
P. G. Agnew, H. D. Arnold, E. F. Burton,
L. W. Chubb, J. C. Clark, C. P. Eldred,
E. P. Hyde, Chester W. Rice, C. E. Skinner.

INDUSTRIAL AND DOMESTIC POWER

A. G. Pierce, Chairman, 2003 Farmers Bank Bldg., Pittsburgh, Pa.
P. H. Adams, E. V. Buchanan, H. W. Cope,
Wm. E. Date, James Dixon, A. M. Dudley,
R. H. Goodwillie, H. D. James, W. C. Kalb,
R. H. McLain, E. H. Martindale, A. H. Timmerman,
L. E. Underwood, H. Weichsel, R. B. Williamson.

INSTRUMENTS AND MEASUREMENTS

S. G. Rhodes, Chairman, 104 E. 32nd St., New York.
C. W. Baker, Wm. M. Bradshaw, H. B. Brooks,
F. P. Cox, F. V. Magelhaes, Charles Robbins,
Clayton H. Sharp.

IRON AND STEEL INDUSTRY

W. F. James, Chairman, 1442 Widener Building, Philadelphia, Pa.
F. B. Crosby, F. D. Egan, Gordon Fox,
Eugene Friedlaender, E. S. Jefferies, W. C. Kennedy,
D. M. Petty, Wm. T. Snyder, Wilfred Sykes,
R. B. Williamson, Fred H. Woodhull, J. D. Wright.

LIGHTING AND ILLUMINATION

C. E. Clewell, Chairman, University of Pennsylvania, Philadelphia, Pa.
G. N. Chamberlin, J. R. Cravath, Terrell Croft,
N. S. Dickinson, Bassett Jones, F. D. Newbury,
P. G. Nutting, R. C. Powell, E. B. Rosa,
W. D'A. Ryan, W. M. Skiff, G. H. Stickney.

MARINE

Arthur Parker, Chairman, New York Shipbuilding Corp., Camden, N. J.
L. C. Brooks, Secretary, Bethlehem Shipbuilding Corp., Bethlehem, Pa.
R. A. Beekman, Eskil Berg, A. R. Cheyney,
Maxwell W. Day, E. G. Gallagher, H. L. Hibbard,
W. F. James, C. A. Jones, C. S. McDowell,
W. P. Meschenmoser, I. H. Osborne, G. A. Pierce, Jr.
J. B. Porter, L. B. Sinclair, H. M. Southgate,
Wilfred Sykes, W. E. Thau, A. E. Waller
F. W. Wood.

MINES

W. A. Chandler, Chairman, H. C. Frick Coke Co., Scottsdale, Pa.
R. T. Andrae, F. H. Armstrong, Graham Bright,
L. C. Ilsley, R. L. Kingsland, A. B. Kiser,
Wills Maclachlan, E. B. Woodward.

POWER STATIONS

Philip Torchio, Chairman, 124 E. 15th St., New York.
J. T. Barron, A. E. Bauhan, E. T. Brandon,
H. W. Eales, W. L. R. Emmet W. S. Gorsuch,
H. P. Liversidge, I. E. Moultrop, Frank D. Newbury,
H. S. Putnam, R. F. Schuchardt, Russell W. Stovel
H. L. Wallau, R. B. Williamson.

PROTECTIVE DEVICES

D. W. Roper, Chairman, 72 West Adams Street, Chicago, Ill.
G. E. Armstrong, P. H. Chase, W. H. Cole,
E. E. F. Creighton, H. W. Eales, F. C. Hanker,
E. M. Hewlett, F. L. Hunt, P. MacGahan,
D. A. McKenzie, A. A. Meyer, L. C. Nicholson,
N. L. Pollard, F. E. Ricketts, Charles Robbins,
T. C. Taliaferro, H. R. Woodrow.

TELEGRAPHY AND TELEPHONY

Donald McNicol, Chairman, 253 Broadway, New York.
O. B. Blackwell R. E. Chetwood E. H. Colpitts
H. W. Drake, W. B. Kouwenhoven, L. F. Morehouse,
R. W. Osborne, W. O. Pennell, L. M. Potts,
S. A. Rhodes, A. B. Smith, D. M. Therrell,
W. H. Winter, D. E. Wiseman.

TRACTION AND TRANSPORTATION

W. S. Murray, Chairman, Room 2800, 165 Broadway, New York.
A. H. Babcock, Reinier Beeuwkes, R. H. Dalgleish,
W. G. Gordon, John Murphy, W. B. Potter,
Ralph H. Rice, Guy A. Richardson, C. S. Ruffner,
N. W. Storer, H. M. Warren.

TRANSMISSION AND DISTRIBUTION

Edward B. Meyer, Chairman, Public Service Electric Co., Newar , N. J.
J. E. Woodbridge, Vice-Chairman, 58 Sutter St. San Francisco, Cal.
R. W. Atkinson, A. O. Austin, Wallace S. Clark,
W. H. Cole, A. W. Copley, M. T. Crawford,
E. E. F. Creighton, F. E. Ricketts, D. W. Roper,
C. S. Ruffner. R. F. Schuchardt, A. E. Silver,
W. K. Vanderpoel.

INSTITUTE REPRESENTATIVES

AMERICAN BUREAU OF WELDING

W. L. Merrill.

AMERICAN COMMITTEE ON ELECTROLYSIS

Bion J. Arnold, Wm. S. Murray, F. N. Waterman.

AMERICAN ENGINEERING STANDARDS COMMITTEE

Comfort A. Adams, H. M. Hobart. C. E. Skinner.

AMERICAN YEAR-BOOK ADVISORY BOARD

Edward Caldwell.

BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY.

L. T. Robinson, Samuel Sheldon. Calvert Townley.

COMMISSION OF WASHINGTON AWARD

John Price Jackson, Charles F. Scott.

COUNCIL OF AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

H. H. Humphrey, John B. Taylor.

ENGINEERING COUNCIL

Comfort A. Adams, H. W. Buck, N. A. Carle,
E. W. Rice, Jr., C. E. Skinner.

ENGINEERING FOUNDATION BOARD

Frank B. Jewett, E. W. Rice, Jr.

FRANCO-AMERICAN ENGINEERING COMMITTEE

A. M. Hunt L. B. Stillwell.

JOHN FRITZ MEDAL BOARD OF AWARD

Comfort A. Adams, H. W. Buck, John J. Carty,
E. W. Rice, Jr.

JOINT COMMITTEE ON ENGINEERING EDUCATION

Charles F. Scott, Samuel Sheldon.

JOINT COMMITTEE ON STANDARD THREAD FOR INSULATORS AND INSULATOR PINS

J. T. Barron.

LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle,
Samuel Sheldon, W. I. Slichter.

NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

The chairman of the Institute's Committee on Safety Codes.

NATIONAL JOINT COMMITTEE ON OVERHEAD AND UNDERGROUND LINE CONSTRUCTION.

Farley Osgood, Percy H. Thomas.

NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

C. A. Adams, Frank B. Jewett, W. R. Whitney.

NAVAL CONSULTING BOARD

Benjamin G. Lamme, Frank J. Sprague.

SPECIAL JOINT COMMITTEE ON DETERMINATION OF POWER FACTOR IN POLYPHASE CIRCUITS

P. G. Agnew, F. C. Holtz, F. Conrad, A. E. Kennelly, S. G. Rhodes, F. P. Cox, Farley Osgood.

U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION

A. E. Kennelly, C. O. Mailloux, Clayton H. Sharp.

LOCAL HONORARY SECRETARIES

Charles le Maistre, 28 Victoria St., London, S. W., England.
Guido Semenza, N. 10 Via S. Radegonda, Milan, Italy.
Robert Julian Scott, Christchurch, New Zealand.
T. P. Strickland, 61 Hunter St., Sydney, N. S. W.
W. G. T. Goodman, Adelaide, South Australia.
James S. Fitzmaurice, Adelaide, South Australia.
L. A. Herdt, McGill Univ., Montreal, Que.
Henry Graftio, Ministry of Ways of Communication, Petrograd, Russia.
A. S. Garfield, 10 Rue de Londres, Paris, France.
Harry Parker Gibbs, Tata Hydroelectric Power Supply Co., Ltd., Bombay, India
John W. Kirkland, Johannesburg, South Africa.

LIST OF SECTIONS

Name	Chairman	Secretary
Atlanta	A. M. Schoen	Thomas C. Taliaferro, S. E. Underwriters Ass'n., Atlanta, Ga.
Baltimore	J. B. Whitehead	L. M. Potts, Industrial Bldg., Baltimore, Md.
Boston	I. E. Moultrop	Ira M. Cushing, 84 State St., Boston, Mass.
Chicago	A. F. Riggs	A. C. King, 8 So. Dearborn St., Chicago, Ill.
Cleveland	B. W. David	W. D. Smoot, Willard Storage Battery Co., Cleveland, Ohio.

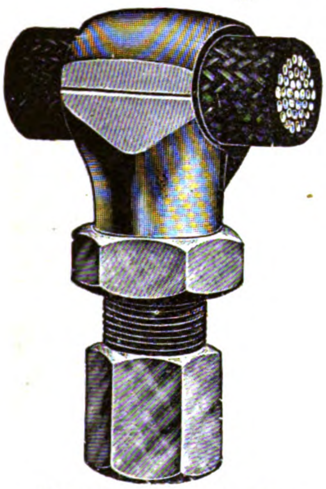
How Dossert Connectors Were Used By the C. M. & St. P. R. R.



DOSSERT CABLE TAP

The cut above illustrates an installation of Dossert Connectors in one of the Chicago, Milwaukee & St. Paul substations in the electrified section.

It shows the 300,000 C. M. starting leads connected by means of Dossert Cable Taps to the 1,000,000 C. M. running leads of the 2,300 volt synchronous motor of the 2,000 K. W., 3,000 volt D. C. motor generator sets.

This railroad also uses Dossert taps to connect the D. C. feeder cables from the main switchboard to the trolley feeders at the point where the latter enter the substation buildings.

Substantial savings can be effected by the use of Dossert Connectors wherever cable connections have to be made, either in the power house, substation or on the feeder system. There is a type made to fit any ordinary joint, and we will design special connectors to meet unusual cases.

Regarding the Advertising Section

Advertisements of equipment, supplies and materials, and other announcements that are deemed of interest to the membership of the Institute and other readers of the JOURNAL, will be published in the advertising section. All advertisers are entitled to listings in the classified Index of Advertisers. Rates will be furnished upon application.

Advertising copy should reach the publication office by the tenth of the month, for the issue of the following month.

The right is reserved to decline to publish any advertisement which the Institute authorities deem unsuited to the JOURNAL.

Suggestions for improvements in the advertising section are invited. All communications should be addressed to the Advertising Department, JOURNAL of the A. I. E. E., 33 West 39th Street, New York.

Classified Advertiser's Index for Buyers

A classified and comprehensive list of manufacturers and agents for machinery and supplies used in the electrical and allied industries; professional consultants and laboratories.

Note: For reference to the advertisements see the Alphabetical List of Advertisers on page 10.

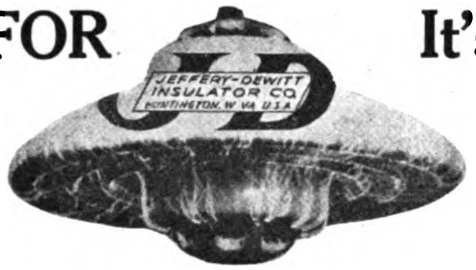
The Merit Is Manufactured Into The Unit. Since The Merit Is In It, If You Miss It Whose Fault Is It? Whose Loss Is It?

NOW This RUGGED Insulator Demands Your Attention

FOR It's



Different

SO

It's Your Duty

to study this insulator directly.

As pioneers in the production of thick porcelain insulators of the unit type exclusively, many obstacles have been overcome.

As pioneers in the precise firing of insulators and in the development of successful methods for checking porosity, we deserve credit and we are adopting every practical method which ingenuity and enthusiasm suggest to guarantee the uniformly high quality of each unit produced.

The demand is constantly increasing but production has broken records too. J-D insulators have proven supreme in safely resisting puncture by lightning and other transient voltages, in safely resisting destruction by power arcs, in standing up under mechanical abuse, temperature changes and rifle bullets.

These things are all admitted or are easily provable by you. Why hesitate when you can get action and results? Visit our largest users and our plant and go home convinced.

SCIENCE ABSTRACTS

Section A: Physics **Section B: Electrical Engineering**

Issued monthly by the Institution of Electrical Engineers, London, in association with the Physical Society of London. With the cooperation of the American Physical Society, the American Institute of Electrical Engineers, and the American Electro-Chemical Society.

The contents of the two sections are as follows:

SECTION A—General Physics; Light; Heat; Electricity and Magnetism; Chemical Physics and Electro-Chemistry.

SECTION B.—Steam Plant, Gas and Oil Engines; Industrial Electro-Chemistry, General Electrical Engineering, and Properties and Treatment of Materials; Generators, Motors and Transformers; Electrical Distribution, Traction, and Lighting; Telegraphy and Telephony.

More than 150 publications including Society Proceedings and other periodical publications, appearing in all parts of the world, are regularly abstracted.

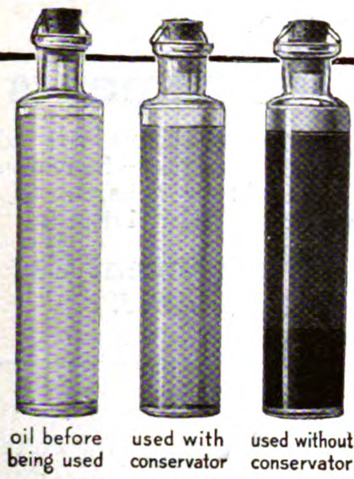
The subscription price is $4.50 for either section separately, or $7.50 for the two together.

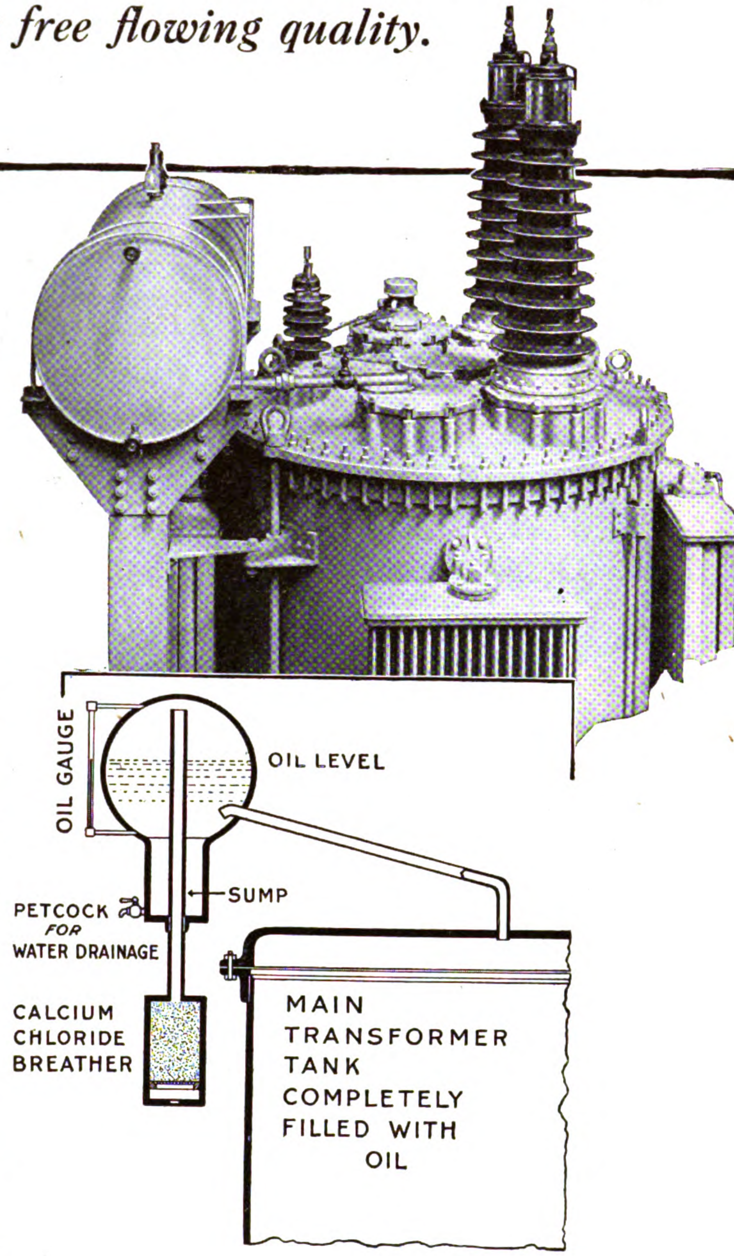
All members of the American Institute of Electrical Engineers can, by special arrangement, subscribe through the Secretary of the Institute at the reduced rate of $3.50 for either section separately, or $5.00 for both sections. Subscriptions should start in January.

The first volume was issued in 1898. Back numbers are available, and further information regarding cost can be obtained upon application to

F. L. HUTCHINSON, Secretary,
AMERICAN INSTITUTE OF ELECTRICAL ENGINEERS,
33 West 39th Street, New York.

The Oil Conservator preserves the dielectric strength of transformer oil and its free flowing quality.





The Oil Conservator Transformer as developed by the General Electric Company consists of a main tank, containing the transformer, which is completely filled with oil, and an auxiliary tank for oil expansion. Connection between the two tanks is restricted so that there is no rapid interchange of oil and the temperature of the oil in the auxiliary tank is always relatively low. Any water that may be condensed in this auxiliary tank is collected in a "sump" and drawn off without coming in contact with the transformer, and main body of the oil.

What the Oil Conservator Transformer does

I. Eliminates "Breathing" and water condensation in main tank, thus maintaining the original insulating value of the oil.

II. Avoids the possibility of explosion by the ignition of a mixture of air and gas vapor from hot oil.

III. Practically eliminates oil decomposition or "sludging" as a result of exposure of hot oil to oxygen.

The General Electric Company offers the Oil Conservator Transformer as a standardized product with its value already fully established in the field and a factory equipment allowing of its economic application to practically all oil insulated "power" units of 500 Kv-a capacity and above.

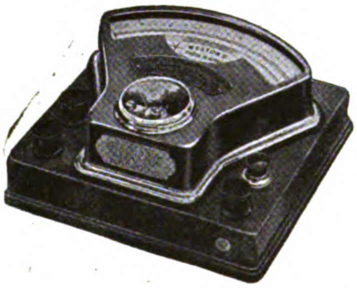
Model 1 D.C.
Portable Voltmeter



Weston Models include complete groups for Portable and for Switchboard Service on A.C. and on D.C. circuits, together with many instruments designed for special purposes. Write for particulars regarding your needs.

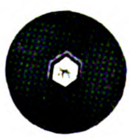
VUL-COT FIBRE

An extremely dense and tough insulator

VUL-COT fibre is especially adapted for all insulating parts that must also function mechanically.

The extra denseness and toughness of *VUL-COT* give it phenomenal wearing qualities even as compared with other fibres and they add enormously to its electrical resistance.

Then too it is much easier to drill, thread or machine generally, because its density is absolutely uniform—no soft or hard spots or fissures.



VUL-COT fibre comes in sheets, rods or tubes, or machined to special shapes and our booklet describes fully its countless electrical and mechanical uses.

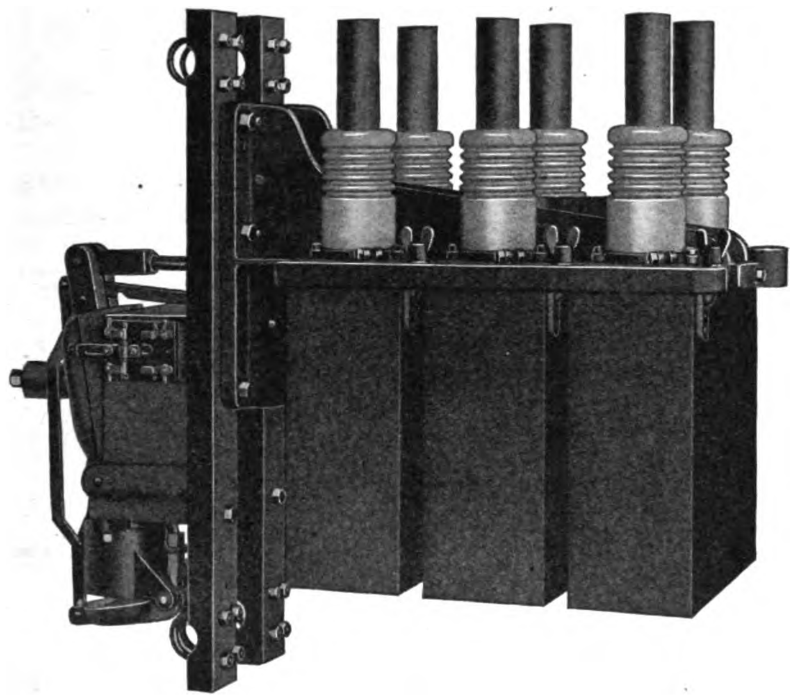
CONDIT

Oil Switches and Circuit Breakers

TYPE D-12



ELECTRICALLY OPERATED—PIPE FRAME MOUNTING
THREE POLE, 500 AMPERES, 15,000 VOLTS.

Condit Type D-12 oil switches and circuit breakers are invariably used to meet demands in controlling and protecting electrical circuits and apparatus where the pressure does not exceed 15,000 volts. They are especially adaptable where space is an important factor, and a relatively high interrupting capacity is desired.

They are *used* principally to control feeder circuits in substations of larger distribution systems and for the control and protection of generators and feeders in industrial service. They are furnished manually operated for panel-frame mounting and remote control for both manual and electrical operation.

Condit Type D-12 oil switches and circuit breakers are furnished in 2, 3 and 4 poles for all standard ampere capacities up to and including 1200 amperes.

If you are interested in the highest degree of protection for your equipment write for bulletin No. 418 at once.

A. I. E. E. PUBLICATIONS

JOURNAL. Published monthly.

Contains technical papers presented at regular Institute Meetings, discussions of Institute papers, reports of various technical committees of the Institute, Section and Branch papers and other articles of an engineering character.

A section is devoted to current Institute news, notices of meetings, reports of committees and of Section and Branch meetings, news of allied societies, personal items, etc.

Subscription price: $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.

Discount of 50 per cent to technical societies and public libraries, and to members for duplicate copies to replace those lost or destroyed.

Discount to Publishers, Agents and Dealers, 10 per cent.

TRANSACTIONS. Published Annually.

Contains such of the technical papers, and reports presented before the Institute as are selected and authorized by the Publication Committee of the A. I. E. E.; also the discussions on the technical papers. The TRANSACTIONS form a permanent record of the progress of electrical engineering.

Existing bound volumes may be purchased by non-members at the following prices:

Paper covered volumes, per year..$10.00
Cloth " " " ".. 11.50
Half morocco volumes, per year, (Price furnished on application.)

The usual discounts of 10% to publishers and dealers and 50% to libraries are allowed on all of the above prices. Members of the Institute are allowed a special price of $5.00 per year for duplicate volumes, in either cloth or paper binding, to replace those lost or destroyed, or for volumes issued prior to their election.

An index to the TRANSACTIONS covering the years 1884 to 1910 can be obtained by members upon application to the Secretary's office, without charge. The index was published in two parts, cloth binding. Price to non-members, $2.00, with usual discount to dealers and libraries.

SEPARATE PAPERS AND DISCUSSIONS.

Most of the recent papers and discussions presented before the Institute can be furnished separately at the following prices:

Single copies of any paper with discussion..................................$0.50
Five or more copies of any papers with discussion..........................each 0.40

Many of the papers printed in Volumes I to IX (1884 to 1892) inclusive, and the Volumes XVII and XVIII (1900 and 1901) are out of print and cannot be furnished. Discounts of 50% to members and libraries; 10% to dealers and publishers.

STANDARDIZATION RULES. Revised Edition, Published 1919.

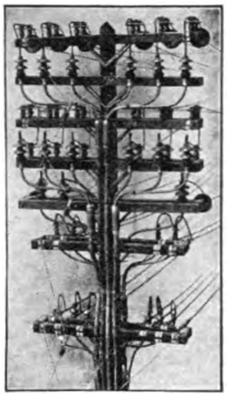
Gives standard definitions of electrical terms, technical data, standard performance, specifications for tests of electrical machinery, standard voltages and frequencies, and general recommendations, as adopted by the Standards Committee and approved by the Board of Directors of the A. I. E. E., November 8, 1918. It also contains the report of the Special Committee of the International Electrotechnical Commission on "Rating of Electrical Machinery."

Price per copy..$0.50
When purchased in quantities of 25 or more, a discount of 10% is allowed.

YEAR BOOK OF THE A. I. E. E. Published annually in February.

Containing lists of Officers, Board of Directors, Committees, Fellows, Members, Associates, and Enrolled Students; Sections and Branches; Constitution, By-laws, and general information regarding the scope and work of the Institute.

Price per copy..$2.00
Single copies will be supplied to members, without charge, upon application.



The Best Engineering Practice

in the installation of lead-covered electric cables requires the same care in protecting the insulation against moisture at the ends as at the joints in manholes.

STANDARD
D. O. A. and D. S. Cable Terminals

provide this protection through their exclusive and patented features suggested by over 37 years experience in the manufacture and installation of lead-covered cables of all kinds.

Standard Graphic Symbols

BY EDWARD J. CHENEY

Chief, Div. of Light, Heat and Power, Public Service Commission, Albany, N. Y.

Symbols have been in vogue since the early ages and are particularly useful to the electrical engineer. Those now in use are the result of growth and evolution and there is no uniformity or agreement. It is desirable to standardize them as far as possible in order to afford simplicity and general usefulness, but it is suggested that the Institute undertake for the present to standardize only those symbols which would be most general and widely used. The general principles which should govern selection are discussed, and there is given a list of suggested symbols covering some of the most important items. These are offered for criticism and suggestions in order to assist toward definite standardization.

WHEN primitive man succeeded in transferring thought between two individuals beyond sight and hearing of each other, one of the first means was by symbols, or crude and roughly cut representations of objects. The limitations of the method need not be dwelt upon. Today, by the manipulation of twenty-six letters and ten figures into countless combinations, we can express upon the printed page anything which language may convey, but still we find the method of our ancestors most convenient in many instances. Particularly in the diagrammatic sketches which are at once a convenience and a necessity to the electrical engineer, do we need to use and understand simple, easily made, and readily recognized symbols for the machines, instruments, and devices whose connections and uses we portray.

In these days, as never before in the world's history, it is unnecessary to argue the desirability of uniformity; of national and international standardization of all things connected with industry. To state the proposition is to have it accepted. Symbols constitute a language, and the more that language can be simplified and the broader its field of recognition, the greater will be its usefulness. We have the language, but there are many dialects; it may almost be said that there are many languages; and if the occurrence at Babel can be reversed, something will be added to the effectiveness of human endeavor.

A sub-committee of the Standards Committee, composed of Dr. P. G. Agnew, Mr. W. A. Merrill, and the writer, assisted by the effective co-operation of many particularly interested and informed engineers, have been investigating the possibility of bringing some degree of order out of this confused situation. It was first attempted to collect and tabulate the symbols used in this and other countries, with the idea that perhaps this alone would solve the problem by disclosing a weight of preference which could be accepted. The result was both instructive and confusing. It was found that there were plenty of symbols; almost every conceivable thing has been symbolized by some one, and most things by many; but of agreement there was very little.

Symbols now in use have been evolved as need arose. In most cases they have attempted to represent the thing indicated closely enough to enable identification. This accounts for much of the confusion, as devices of the same class are so varying in appearance. It also accounts for much of the complication, the attempt to portray the object frequently resulting in something more like a picture or a working drawing than a true symbol. Slight variations in type or appearance are indicated by corresponding changes in the symbols, and in many instances the results are not, and never will be, interpreted except by the few initiated. In justice it should be said that some are so widely used as to be generally recognized, and these afford a foundation upon which to build. It should also be said that there has been found no reactionary desire to cling to the particular symbols now used, but on the contrary there is a generally expressed willingness to accept any thing upon which there can be general agreement.

There is practically no limit to the things which can be symbolized, and one of the first questions is to define the Institute's scope. Obviously the adoption of too many symbols would approach the situation of Chinese writing; only the specially trained would be able to interpret, and the aim would be defeated. There is also grave question whether the Institute is warranted, for the present at least, in going into special fields, or dealing with anything except of general application. It is believed that the Institute might properly standardize such symbols as will be used in papers which are presented to it, or in connection with diagrams of a general nature; but should not, unless by agreement with the interests affected, try to fix all symbols needed for special fields, such as full connection diagrams for switchboards, control equipments, or telephone, telegraph and radio apparatus. The National Electrical Contractors' Association, for instance, has a set of standard symbols, extremely useful to them, and regarding which they are unquestionably the best judges. It is to be hoped, of course, that the various special fields will use the standard general symbols and co-ordinate their special symbols with them.

It is suggested that the symbols included in a stands ard list should conform to the following principle- so far as possible:

a. Be adapted to universal use.
b. Be simple and easily made.

To be presented at the 8th Midwinter Convention of the A. I. E. E., New York, February 18, 1920.

c. Be flexible; *i.e.*, permit indication of as many things as possible without additional symbols and permit simple modifications or extensions for special cases.

d. Be indicative in appearance.

e. Be those most used at present.

In order to elicit suggestions and criticisms the list of symbols shown in Plates 1, 2 and 3 are presented as conforming to the foregoing principles and covering some of the most important items.

1. *Conductors.* It is rather common to show conductors crossing, but not connected, as in Fig. 1, but this makes the construction more difficult and seems unnecessary. The absence of a dot should be sufficient indication that there is no electrical connection.

Fig. 1

2. *Earth Connections.* This is quite generally used and seems to be satisfactory.

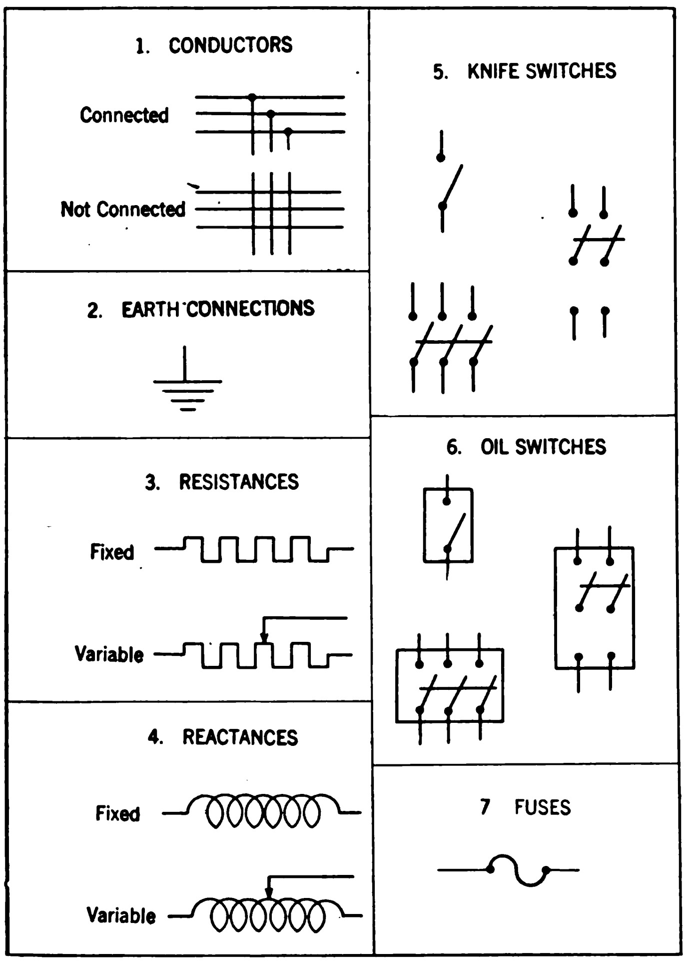

Plate 1

3. *Resistances.* 4. *Reactances.* 9. *Windings.* These three should be considered together because of the way they are confused in current practise, although it is important that they should have distinctive symbols. At present the zigzag line (9) is used rather indiscriminately to represent all three. The rectangular line (3) is frequently used for resistance (sometimes for iron grid resistance only), but never for anything else, and seems to meet all requirements for a resistance symbol.

The succession of loops (4) is indicative of reactance and is widely used for that purpose in text books and elsewhere. Apparently the only objection raised against it is its alleged difficulty of construction. Its construction can be made difficult, but need not be. The loops in Plate 1 are drawn with one sweep of a compass, 5/6 of a circle being drawn about each center except the end ones. No spacing is necessary; each new center is placed by eye just far enough outside the preceding arc to allow for the ink line. Drawn in this manner, which was independently developed by Mr. J. P. Buckley but apparently by others also, the looped figure is easier to construct than either of the others.

This leaves the zigzag line to denote windings of all kinds, thus the three as shown are submitted as a solution of perhaps the most perplexing of the problems involved.

5. *Knife Switches.* 6. *Oil Switches.* The convention for knife switches will probably be generally accepted, but the indication of an oil switch by putting a rectangle around the corresponding knife-switch symbol is probably novel. The advantages of the system are fairly obvious.

The English indicate live and dead sides of a switch by having the conductor terminate in an open circle at the dead side and in a full dot at the live side, but this makes construction difficult, may sometimes be misleading, and seems to be an unnecessary complication.

7. *Fuses.* This is the old symbol, designed, apparently, to represent a wire of soft metal twisted around two binding posts. Cartridge fuses are commonly shown as in Fig. 2 but this is not sufficiently general. The symbol shown on Plate 1, constructed with two half circles, is easy to make and quite distinctive.

Fig. 2

8. *Circuit Breakers.* Existing symbols are mostly sketches of some particular type of breaker. The symbol suggested will probably be generally recognized, is sometimes used now, and is distinctive.

10. *Transformers.* The symbol for transformers will naturally follow if (9) (for windings) is accepted. Of course there ought to be further elaboration to permit indication of polyphase transformers and different bank connections, but that has not been undertaken as yet.

11. *Rotating Machines.* A circle, with conductors coming to the periphery, is used as the general symbol. Small rectangles, representing brushes, will indicate direct-current machines. Letters inside the circle will give any additional information desired. Mechanical connection is shown by a line joining the centers.

12. *Meters and Instruments.* This is the same as

for rotating machines except the conductors will come to dots inside the circles.

13. *Shunts.* This is the symbol generally used. Sometimes the shunt circuit conductors are brought to a separate set of dots as in Fig. 3, but this seems to be an unnecessary complication.

FIG. 3

14. *Relays.* A confusing multitude of symbols is now in use. The system suggested is uniform with that for machines and meters except that a rectangle is used.

15. *Batteries.* The general symbol is that commonly employed but it seems desirable to differentiate between primary and secondary batteries, and the suggestion is to put a rectangle around the "plates" to indicate a storage battery.

In using this symbol it ought to be understood that the long, thin line is the positive terminal, and this convention should be rigidly adhered to whenever polarity is of importance.

16. *Lamps.* These are almost universal.

17. *Condensers.* This is the most commonly used symbol and seems to meet all requirements.

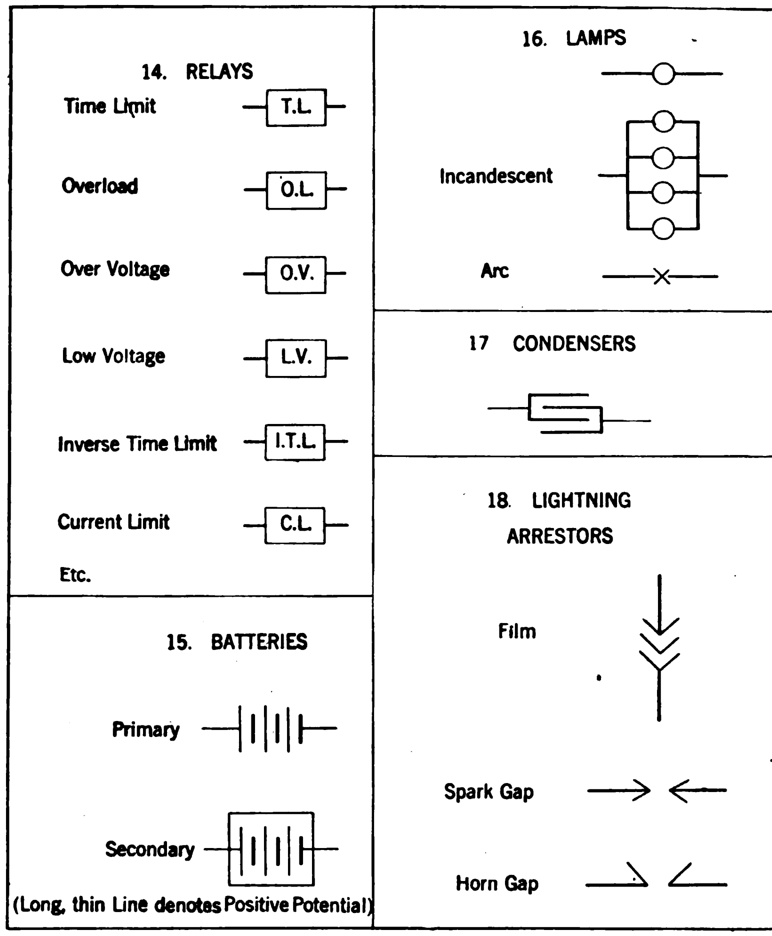

PLATE III.

18. *Lightning Arresters.* There are many types and many symbols. The three symbols shown will doubtless be readily recognized and cover the most general cases.

CONCLUSION

After all interests and all views have been fully considered, it is suggested that this group of symbols, modified as may appear advisable, should be included in the standards of the Institute, there to be added to from time to time as occasion warrants. It will, of course, be desirable to secure as much international agreement as possible. In this connection it should be said that the practise of other countries has been given full weight in determining the symbols herein suggested.

The author is indebted to his fellow subcommittee members and to many others for suggestions, and it is hoped that this paper will arouse general interest and bring forth criticism and constructive suggestions which will enable definite decisions to be reached at an early date.

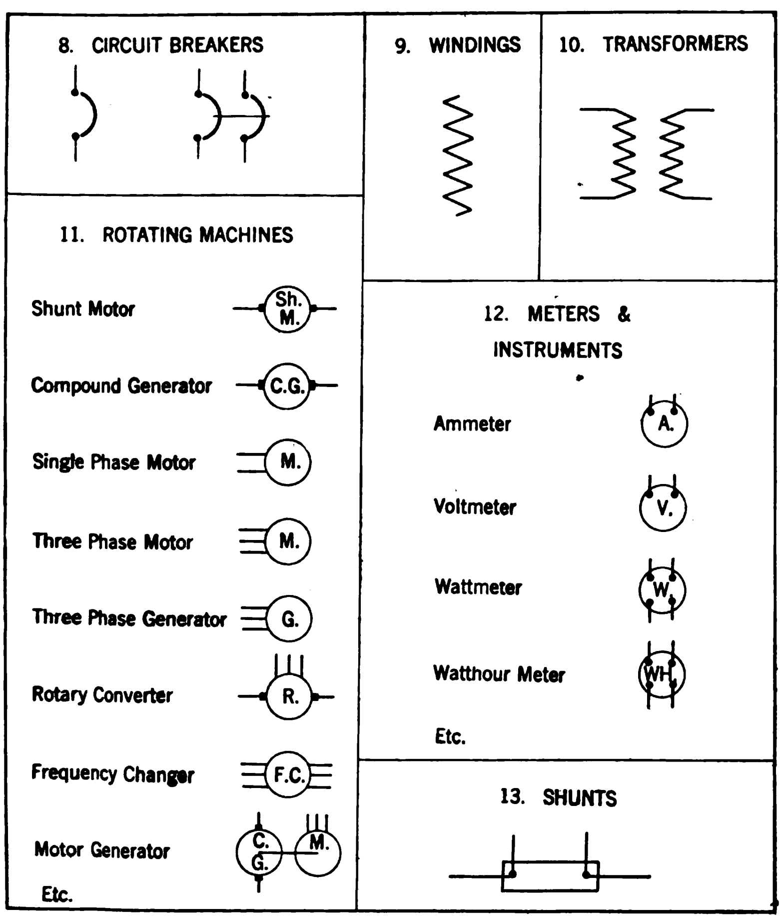

PLATE II.

The Measurement of Projectile Velocities

BY PAUL E. KLOPSTEG
Physicist, Sales Department, Leeds and Northrup Co.
AND
ALFRED L. LOOMIS
Formerly Major, Ordnance Dept., U. S. A.

The paper discusses the requirements imposed by proving ground practise upon a chronograph which is intended for general ammunition testing. Instruments of the standard pre-war pattern were entirely inadequate in number for testing the immense quantities of ammunition contracted for by the Government during the war. The development work undertaken to cope with the whole problem of velocity testing was first directed towards devising methods for speeding up measurements with the existing instruments. Conditions made it necessary to lay aside this work and concentrate upon the development of a totally new device for obtaining the results both speedily and accurately. The instrument which was developed, and adopted as a standard ordnance chronograph, is designated "Aberdeen chronograph." An account of its development is given. It is an assembly of many standard parts, with a few necessary special ones. Rapid production of the instruments was thereby made possible. The Aberdeen chronograph, and the procedure in determining velocities by this means, are described in detail. For the sake of comparison, the Boulengé chronograph is briefly described. Comparative results as to speed and accuracy of measurement are given.

Introductory

One of the very important measurements which must be made at an army proving ground is that of projectile velocity. Not only is it essential that such measurements be made, in connection with ammunition testing and development, but it is equally essential that the results be reliable. Data of the greatest accuracy are needed in certain problems of experimental development. Velocity measurements for the computation of range tables must be as free from error as possible. In making powder tests, seven "uniformity" rounds are fired; the measured velocities, for acceptance of the powder, must agree within narrow limits. Rejection of a lot usually means the rejection of thousands of dollars' worth of material.

The difficulty of making these speed tests is increased by the fact that the portion of the flight of a projectile with which we are directly concerned, is an extremely transient phenomenon. The interval during which the shell lends itself to the measurement is of the order of hundredths of seconds. This fact adds a third difficult requirement to the two above mentioned, namely, certainty of obtaining the record when the projectile passes. Failure to do so necessitates the firing of an extra round, sometimes at a cost of hundreds of dollars. During the emergency there were several additional requirements. The apparatus had to fulfill the demand of giving good results day after day, under all conditions of weather, and this in the hands of operators without technical training.

It was recognized in the early summer of 1917 that when deliveries of the immense quantities of ammunition contracted for by the government would commence, the matter of making the necessary velocity tests quickly and accurately would prove an embarrassing problem. The existing chronographs, of the Boulengé pattern, were limited in number, and manufacture of enough of these instruments in time to meet the situation was, because of their mechanical complexity, out of the question. In order to represent adequately what the problems were and how they were met, we shall first make brief mention of some of the characteristics of the Boulengé chronograph. A fuller description is contained in War Department Circular No. 1682, and in the 5th edition of Foster's Handbook, page 1128.

In all the various practical instruments devised for velocity determinations, the measurement is that of the time interval required by the projectile to traverse a measured section of its path. With the Boulengé chronograph, this section is included between two wire screens, the breaking of which by the projectile actuates the recording mechanism. The latter utilizes two electromagnets, each in series with one of the respective screens. These magnets, by virtue of the current through them so long as the screens are intact, support, respectively, a rod to receive the record, and a weight, to release a marking "knife" by falling upon a trigger. The rod and weight are intended to fall freely under the action of gravity. The origin of readings on the rod is the mark made by the knife when the rod is suspended. A simultaneous break of circuits of the two magnets, produced by a device called a disjunctor, produces a second mark, somewhat higher up, which represents the time required by the instrument to function. When the projectile is fired through the screens, it breaks, first, the circuit of the magnet supporting the rod, then that of the circuit supporting the weight, thus making a third mark, still higher up on the rod. Measurement of the distances from the origin of readings to the two other marks mentioned gives the data from which the time interval may be turned up in tables. From the interval so found, the velocity is determined by the usual formula.

For the sake of a later comparison, statements should be made as to the accuracy, and as to the best conditions for precision of measurement with the Boulengé chronograph. Cranz in his "Lehrbuch der

To be presented at the Midwinter Convention of the A. I. E. E., February 19, 1920.

Ballistik"—which is probably the most authoritative work on ballistics yet produced—states that a given Boulengé chronograph is capable of repeating its reading of a certain time interval to 0.0001 second; but that, because of certain constant errors, which are very difficult to avoid or to determine with certainty, the absolute value of the time interval as measured by the instrument is, at best, reliable to 0.001 second. This statement is fully borne out by experience. The interval most favorable for precision of measurement being about 0.11 to 0.12 second, the distance between screens should be variable so that the distance best suited to a particular gun may be used. With the 155 mm. gun, for instance, this distance is 200 feet; on account of the blast, the first screen is placed about 100 feet from the muzzle. As a result, the second screen must be very high, even with moderate elevations of the gun. Thus, with an elevation of but thirty degrees, the second screen must be about 175 feet above the level of the gun. It is needless to point out, perhaps, that a movable screen support which can rigidly hold a screen at a height of 175 feet, has not yet been built. Even were this possible, the time consumed in hauling down a screen from a height of 175 feet, repairing or replacing it, and hauling it up again, would be so considerable as to render rapidity of testing quite impossible. The immediate remedy may be sought in a greatly shortened screen distance. In this case, of course, a more accurate recording instrument would be desirable.

In addition to the undesirable feature of requiring so much time for replacement, the wire screens have another serious drawback, which has repeatedly been mentioned in the writings of the Germans, the French and others upon the subject, and which thrusts itself upon the attention of anyone making a careful study of them. This is the very considerable uncertainty as to whether the recorded interval actually and accurately corresponds to the interval taken by the projectile to travel the measured distance between screens. The uncertainty is due in part to persistence of contact of the wires with the projectile, even after they are broken; in part also to the fact that the instant of break depends somewhat upon whether a wire is squarely hit by the tip of the projectile, or whether the tip strikes through the screen between neighboring wires. It happens occasionally—in spite of the fact that the wires are ordinarily spaced about one-third of a caliber apart—that the projectile slips through the screen without breaking a wire.

With the idea of eliminating the wire screens as the signaling end of the Boulengé arrangement, one of the writers in the summer of 1917 presented to the Sandy Hook Proving Ground a plan for "wireless" screens which had occurred to him some months before, in connection with other work upon the measurement of short time intervals upon which he had been engaged. Essentially, a screen of the type proposed was to be a mutual inductance coil of sufficiently large diameter to permit firing a projectile through it without great risk of injuring the windings. If a steady magnetic field is set up within such a coil by a current through one of the windings, it follows that any sudden disturbance of the field—by the passage of a projectile of magnetic material, for example—will produce a corresponding momentary electromotive force in the other winding of the coil. Preliminary tests showed the supposition to be correct.

For the purpose of developing this idea into a routine method, and to work upon other related problems, one of the present writers entered upon work at the Sandy Hook Proving Ground as Electrical Engineer in the Ordnance Department. The preliminary work was carried on at the Bureau of Standards, where facilities were kindly offered, and where much splendid cooperation was given, particularly by Dr. P. G. Agnew and Mr. W. H. Stannard. At the same time other possible solutions of the problem of speeding up the tests were being considered, and apparatus was being built. Frequent trips were made to Sandy Hook for field tests, which had to be made under very adverse conditions on Saturday afternoons and Sundays, so as not to interfere with routine firing.

The inductor scheme as partially developed was put to actual test, with very promising results; the Boulengé chronograph used with two such coils to all appearances functioned in the same manner as though the projectile had broken the usual type of wire screens. Unfortunately the work had to be discontinued before the development could be considered through the experimental stage, because of the removal of the proving ground from Sandy Hook to Aberdeen, Md. Here experiments with the coils became prospectively impossible for some months, and the work was concentrated upon another device which seemed to hold considerable promise, and with which tests could more readily be made. This device had been constructed at the Bureau of Standards for the purpose of recording signals produced by the "bow wave" of the projectile. The instrument which was finally evolved was called the Aberdeen chronograph. Work upon the inductor screens was not resumed because the newly developed instruments met all the needs which necessitated the development work, and their rapid production, as well as other problems occupied attention until the close of the war. It has been reported recently, however, that the inductor method is being applied with success in England.

Development of the Aberdeen Chronograph

The device mentioned in the preceding paragraph consisted of a Leeds & Northrup governed motor, on the vertical shaft of which was mounted a flywheel with a smooth rim. A strip of paper could be fastened upon the rim to receive the records produced by the projectile when it actuated the signaling device. Up to this point the instrument differed from previously

described ballistic chronographs only in that a constant speed motor was used. All such chronographs, however, utilized the breaking of wires for the signals,

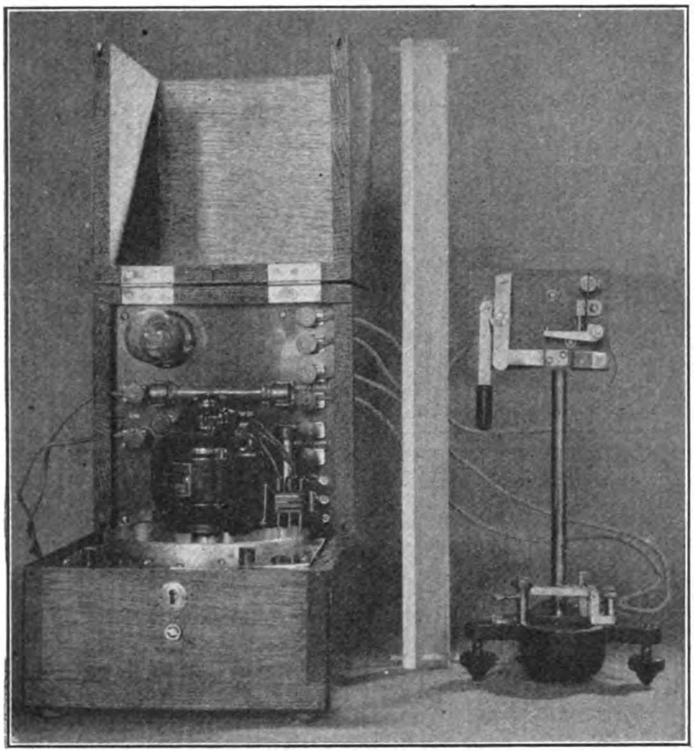

Fig. 1—Aberdeen Chronograph, Fall Apparatus and Direct-reading Velocity Scale. Instruments in Operating Position.

the interruption of the current producing a spark from a point in close proximity to the rapidly revolving drum. In this case, the recording system was designed for open circuit operation, *i.e.*, the spark was to occur when a circuit was closed by the projectile. In connection with such circuits, it had been planned to use automatic contacts which should close when the bow wave of the projectile impinged upon them. The task of constructing such switches so that they would operate unfailingly and under all conditions proved formidable. The greatest possible speed in getting something usable remained imperative, and the urgency became greater as time passed.

It then occurred to one of us to try a new form of screen, or better, a form of contact target, in which contact should be established mechanically by the tip of the projectile. This target in its simplest form consists of a pair of metal sheets, of suitable thickness, separated by an insulating layer. Experiments immediately demonstrated the success of such an arrangement. Thus, the recording mechanism arranged for "make" circuit signals, together with the contact targets, became a most promising basis for further work of development.

On March 2, 1918, a modified design of the Mark I instrument* was taken to the Leeds & Northrup Company, and on March 15th three of the new Mark II instruments had been completed and were ready for operation at Aberdeen. These three instruments were used daily in routine measurements, in a shanty of rough boards on the gun platform, and so successful were they that it was decided to proceed immediately with the construction of the instruments in quantity. A new design, Mark III, including valuable suggestions from the manufacturers, was worked out which, with the exception of minor details, became standard. In these, of course, the faults revealed by experience with the Mark II instruments were eliminated. Much experimenting in the laboratory and under service conditions was carried on in the meantime on both the electrical and mechanical components of the apparatus. Several further improvements were made, and from this point the production of Mark IV Aberdeen chronographs in lots of 25 proceeded without delay.

An important factor in the success of the Aberdeen chronograph in the emergency, aside from questions of its excellence as an instrument, was the fact that from the time production began until the last instrument needed had been delivered, the average rate of production per working day was one complete instrument. This became possible, even with manufacturing facilities already overtaxed, because the design included many standard parts.

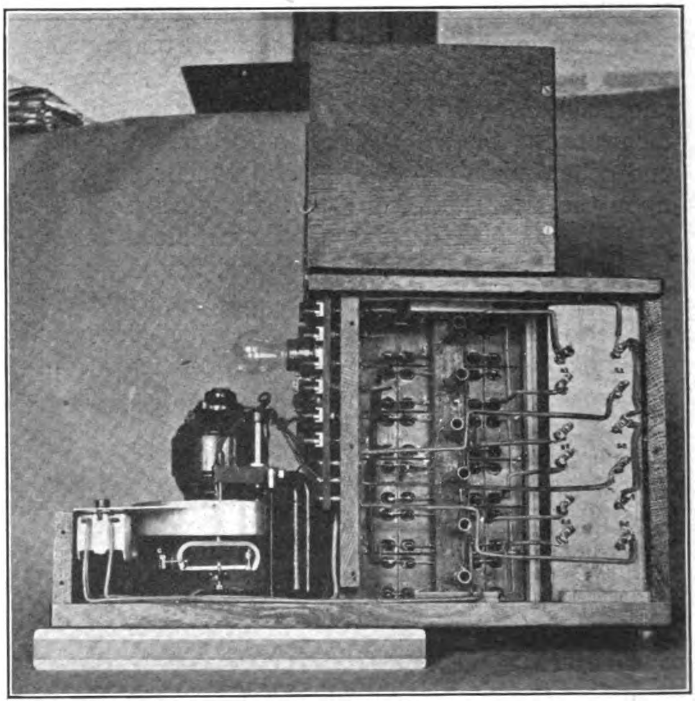

Fig. 2—Aberdeen Chronograph, Side View, with Case Opened for Inspection of Parts

Description of Mark IV Aberdeen Chronograph

Fig. 1 shows the chronograph ready for operating, and Fig. 2 is a side elevation, with the case open for inspection of the circuits. The size of the apparatus

*Mark I, Mark II, etc., is the War Department designation of successively developed types of ordinance material.

may be judged by comparison with the 12 inch scale, shown in the latter view. In Fig. 3 the case of the chronograph is shown closed, with the carrying handle attached.

The mechanical part of the device is seen by reference to the photographs to consist of a shallow cylindrical drum of aluminum, mounted on the vertical shaft of a small (110 volt direct current) motor. On the lower end of the same shaft is carried the constant

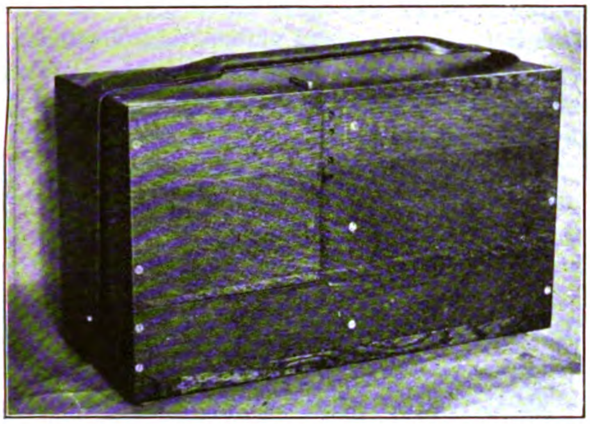

Fig. 3—Chronograph in Closed Case with Carrying Handle

speed governor, upon which depends, in large measure, the accuracy of the instrument. It is a development of the governor used in the Leeds & Northrup temperature recorder. The function of the governor is to control the power input into the motor. Its *modus operandi* may be understood by reference to Fig. 6. A thorough analysis of the device resulted in the design illustrated, which is capable of holding the speed so constant that the mean deviation from average speed, as determined in repeated tests over a fixed 0.2 second interval, was less than 1/10 per cent. Another way of representing this fact is in showing the results of a series of observations. Taking 100 measurements of a 0.2 second interval, 62 were within 0.04 per cent of average speed; 70 within 0.05 per cent; 77 within 0.06 per cent; 95 within 0.07 per cent; 97 within 0.08 per cent; and 100 within 0.09 per cent. In these measurements, therefore, it is safe to assume a maximum probable error of ± 0.1 per cent. A speed of 25 rev. per sec. is thus maintained; the method for checking this value will be described later.

A specially prepared strip of paper receives the record marks. The paper, which is blue, has a thin coating of white paraffin on one side. When a spark passes through the paper, it not only perforates the latter, but also melts a tiny bit of the paraffin, leaving a bright blue, easily distinguishable spot. The width of the strip is equal to the depth of the cylindrical drum, and its length to the inner circumference of the drum. It is held in position very firmly against the smooth inner surface of the drum, on account of the rapid rotation of the latter. By this arrangement, much saving of time is effected, since the record strip may be easily inserted in the drum, and, with a little practise, removed while the motor is running at full speed. With the speed mentioned, and an inner circumference of the drum of 500 mm., the paper strip is given a linear speed of 12,500 mm. per second. Thus a very open and uniform time scale is secured. Three spark points (Fig. 6), in the same vertical line, are held within 1 mm. of the record strip by an insulating block. A spring latch holds the points either in the recording position or at some distance from the paper.

Reference to Fig. 6 shows that one of the electrical spark-recording units consists essentially of a condenser, and the primary of a transformer, both in a circuit with the contact target. Up to the instant of firing, the condenser is kept charged through high resistances, from the supply line which furnishes the power for the motor. The supply line of 110- or 220-volts direct current, is connected at AB. When the tip of the projectile strikes the target, contact is established between the plates, and a discharge passes through the transformer resulting in a spark from the corresponding recording point. The main condenser has a capacity of 10 micro-farads. Later work showed

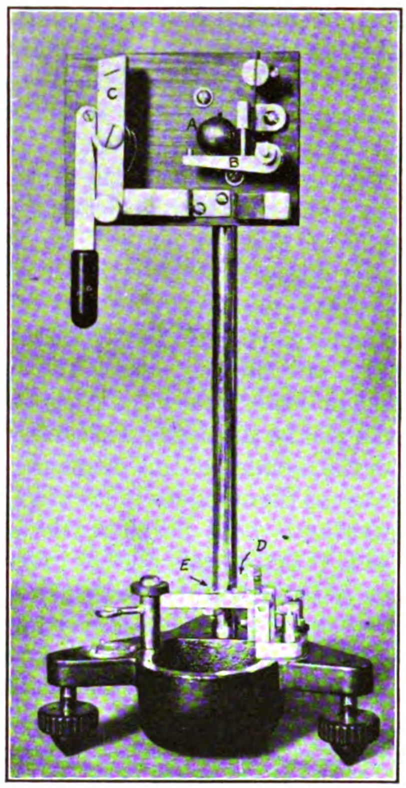

Fig. 4—Fall Apparatus for Verifying Accuracy and Constancy of Motor Speed

that an auxiliary condenser of 6 microfarads, connected in parallel with the plates of the contact target, greatly intensified the spark. The complete circuits are shown in the diagram. Three recording units were provided, as shown. Normally two only were

used, the third being for emergency, or for use in cases where average velocity values over two adjacent sections of the trajectory were to be determined on the same instrument.

A ready means for verifying the speed of the rotating drum is essential, to give the operator confidence in the performance of his instrument if for no other purpose. If we could, in some manner, produce two sparks, separated by an accurately-known short interval of time, we should have a ready means for checking the accuracy and constancy of the motor speed. A device which could be utilized for this purpose had previously been worked out in connection with psychological time measurements.* This is a "fall apparatus," the modified form of which for use with this chronograph is seen in Fig. 1, and shown in detail in Fig. 4. A ¾-inch steel ball *A* rests upon a spring-supported horizontal lever *B*. When the counterpoised hammer *C* which is under spring tension is released, it strikes the end of the lever a smart blow, knocking it clear of the ball. At the instant of striking, the contact between the hammer and lever produces a spark from, say, the uppermost spark point in the drum. Simultaneously the ball begins to fall. When it reaches the bare wire *D*, held on an insulated post, it makes a wiping contact with the latter, and then touches the tungsten plate *E*, between which and the wire it closes the second circuit. At the instant contact is made at *E*, a second spark jumps, say from the next lower spark point. Obviously we may adjust with great exactness the distance between the lowermost point on the ball, when it is in position on the upper lever, and the plate *E*, so that the time of fall between these two points is 0.2 second. This corresponds to five revolutions of the drum. If the speed of the latter is correct, two marks will be found upon the strip, one directly above the other. With slightly higher or lower speed than the correct value, the two marks will be displaced with reference to each other. From the amount of this displacement the constant error in speed becomes easily known. Thus, when the fall apparatus is kept permanently connected as shown in Fig. 1, it is a simple matter at any time during the course of the day to calibrate the chronograph. In practise, the speed remained so constant in a day's run that calibrations were made only two or three times during the day.

Fifty feet was chosen as the standard distance between targets for all velocities from 500 to 2500 feet per second. With a fixed distance between the contact targets, and fixed speed and dimensions of the drum, there is a one-to-one correspondence between distance between record marks and velocity. Thus it becomes possible to construct a direct-reading scale for velocities which is suitable for all the values between the limits mentioned. The scale was so designed that, when the shot was fired, regardless of the relative positions between the spark points and the abutting ends of the record strip, the velocity readings could be made without possibility of mistake. The scale is shown in Fig. 1, and again in the photograph of the accessories case (Fig. 5). This picture also shows the fall apparatus taken apart and in the case.

In its contact target arrangement, already described, the Aberdeen chronograph is unique among the ballistic chronographs. The fact that the recording spark occurs when the tip of the projectile establishes contact between the metal plates has the consequence that the otherwise great uncertainty in the distance between the points at which the signals occurred is practically eliminated. It may here be repeated that such uncertainty is probably the chief point of weakness, so far as accuracy is concerned, in the ordinary wire screens used with the Boulengé chronograph. That such errors are truly minimized with the contact targets is shown by the fact that the distance between targets could be reduced to 25 or 30 feet without seriously affecting the agreement among several instruments measuring the same time interval.

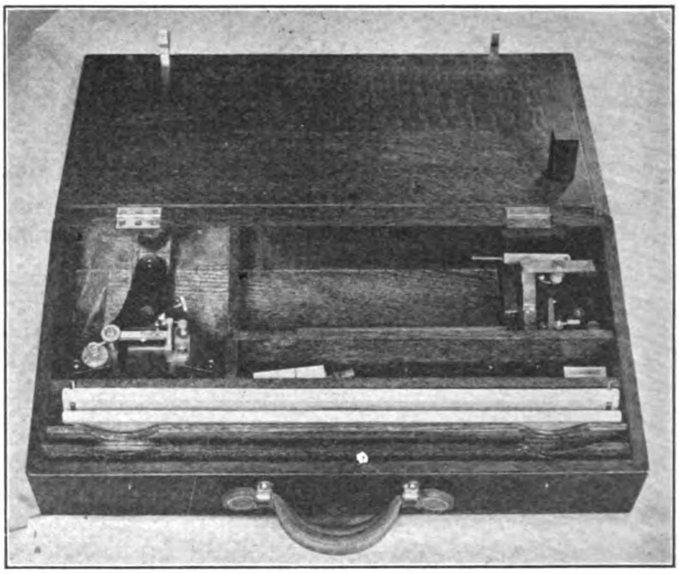

Fig. 5—Accessories Case with Necessary Auxiliary Apparatus

Procedure in Velocity Measurements

The application of the Mark IV chronographs to velocity measurements in such a way as to secure the data with minimum loss of time was in itself a development problem. Three instruments were used with the same pair of contact targets, and the observations were independently made and entered in the data book by three respective observers. The averages were then entered in a fourth book, together with the necessary accompanying data as to the gun, kind of projectile, etc.

The contact targets were made up beforehand in quantity. For the three-inch guns they consisted of lead

*Klopsteg, *Journal of Experimental Psychology*, II, 253, 1917.

foil strips about 3-in. by 12-in. which were attached with hot paraffin to the opposite sides of a sheet of paraffined building paper 5-in. by 17-in. Much of the routine firing was done with constant elevation of the guns, so that permanent supports for the screens could be used. These supports consisted of uprights, each of which had two cross-arms at the proper height, extending out on one side. The lower cross-arm was provided with a spring clamp, on the insulated inner surfaces of the jaws of which there were contact buttons which made connections with the lead foil sheets. The upper arm also carried a clamp which supported the contact target in a vertical position, and between the two clamps the target was held with sufficient firmness to prevent its being moved appreciably by the wind. From the contact buttons on the lower clamp, tion figure for "reduction to muzzle"* and for motor speed is added, and the corrected reading put down. All this is about a half minute's work. In the meantime, the detail of men outside has replaced the screens and reloaded the piece, and the next shot may be fired. In this manner velocities could be measured at an average rate of one round per forty-five seconds, or from three to five times as rapidly as by the older method. The advantage of speed of measurement is indicated by the fact that, although the Aberdeen Proving Ground was not established until January, 1918, and the new chronographs were not put in regular service until June, seventy per cent of all velocity measurements made at the Aberdeen Proving Ground before the cessation of hostilities, were made with Aberdeen chronographs.

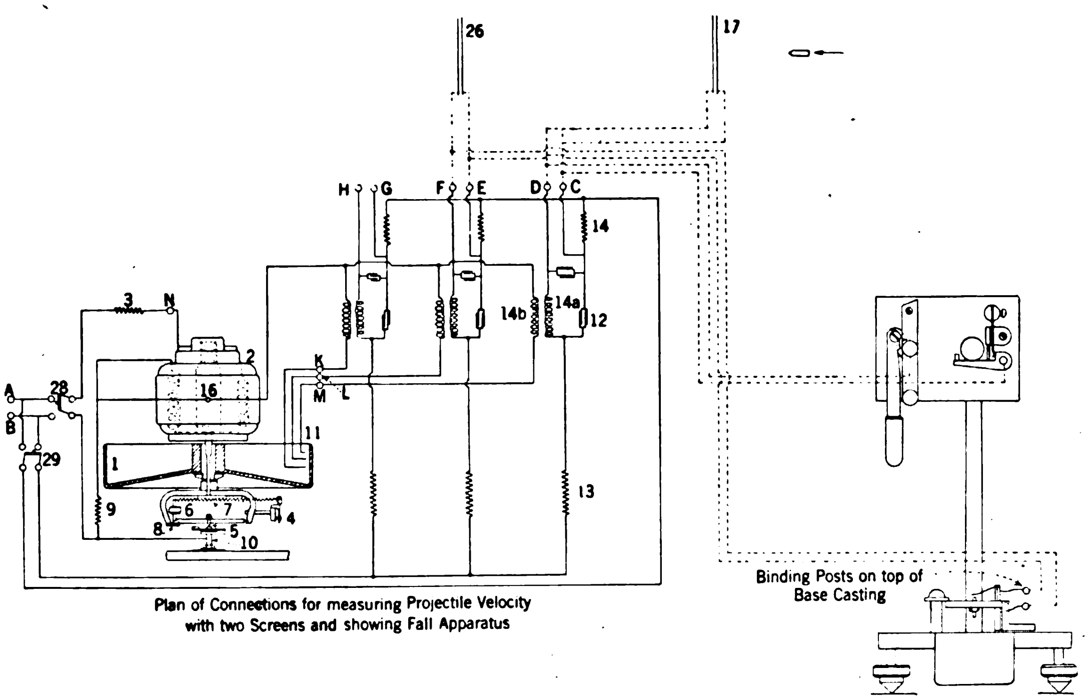

Fig. 6

wires were run in conduit to the instrument building, just behind the gun platform.

In undertaking a series of measurements, the motors are started running, and their constancy and accuracy of speed verified by a test with the fall apparatus. In the meantime, the gun is made ready and the contact targets put in place. The strips on which the "check records" are made are removed, and clean strips spun into the drum. The instruments may then continue to run *ad libitum* until the shot is fired. The motor switch button is then turned off, the strip with the velocity record removed and a new one inserted. (All strips are marked beforehand for proper identification). With the direct reading velocity scale, the velocity is read directly from the strip, and entered in the record book. The proper correc-

A comparison of the two types of chronographs, Boulengé and Aberdeen, brings out clearly the fact that the former is distinctly a laboratory instrument, requiring a very stable foundation at a minimum distance of several hundred yards from the gun platform, while the latter is a field instrument, which may be and is being used immediately behind the gun platform; or it may be set upon the ground as near the gun as may seem desirable. Proximity to the gun does not affect the records. The facts previously mentioned with reference to the two types of instruments may already have suggested that, while it takes

*By "reduction to muzzle" is meant the process of transforming the observed velocity to that which obtained at the muzzle, on the assumption that the projectile experienced uniform retardation from the instant it left the gun.

skilled operators, who are thoroughly familiar with the sources of error in the Boulengé and how to avoid them, to get acceptable results, the Aberdeen chronograph has from the outset been successfully used by operators who had had no previous training; they were enlisted men, taken from the ranks.

Many competitive tests as to accuracy were made during the process of development, measuring the velocity of the same projectile with a set of three Boulengé and a set of three Aberdeen chronographs. Average dispersions* for twenty rounds were computed for many series of firings. Invariably the average dispersion with the Boulengé chronograph was from two to four times as great as with the Aberdeen. In routine firings, the three Aberdeen chronographs agreed within one or two feet per second on a velocity of 1700 feet per second, and only rarely did the maximum dispersion at this value become as great as 5 feet per second.

One source of gratification is the fact that in spite of the "momentum of custom"—a phrase borrowed from a recent article upon the subject—the Aberdeen chronograph was one of the few devices developed under the pressure of necessity, which was fortunate enough to find a place in actual service of the government, and to play an important part in increasing the efficiency of the immense program of preparation which was so well under way when the armistice put an end to the hostilities.

*By dispersion is meant the maximum difference between any two of the three instruments used. The average dispersion is the sum of the dispersions divided by the number of rounds.

INVESTIGATION OF CHILLED IRON CAR WHEELS

For over half a century, the majority of the freight cars in use in the United States have been carried by chilled cast iron wheels. These wheels have given general satisfaction even under the greatly increased stresses due to the heavy rolling stock now in use. It has been noted for several years, however, that failures of freight car wheels occur quite frequently at the foot of long and steep grades. The cause of such failure appears to be the heating of the wheel produced by the prolonged application of the brakeshoes, this rise in temperature causing complicated stresses in the structure of the wheel. The stresses thus produced may be sufficient to cause cracking and failure and in all probability a derailment of the car under which the wheel is placed.

In order to determine the exact temperatures in different portions of the wheel, after prolonged heating of the rim, the Bureau of Standards has instituted a complete investigation of this subject. It is obvious that temperature measurements cannot readily be made upon a wheel in service and considerable ingenuity has been shown in perfecting a laboratory apparatus capable of producing conditions analogous to those met with on the road. The wheel is mounted in a vertical position and surrounded by electrical resistance coils insulated from but setting close against the rim of the wheel. Holes are drilled at all points at which it is desired to obtain temperature measurements and into these openings thermocouples are inserted. It is possible by regulating the flow of current through the resistor to raise the temperature of the rim to any desired amount, and the corresponding temperatures at other points may then be read. Quite a number of wheels have already been tested and others are being submitted from time to time by parties interested in the work.—*Technical News Bulletin*, Bureau of Standards.

WATER POWER BILL PASSED BY SENATE

January 15th the Senate passed the Water Power Development bill which is generally similar to the measure passed by the House last July, but contains some points of difference. The bill has been sent to conference for adjustment of House and Senate differences.

The bill as passed by the Senate provides for creation of a Federal Water Power Commission, composed of the Secretaries of War, Interior and Agriculture, which would be authorized after investigation, to issue licenses for development of water-power projects. The licenses would run for fifty years.

The measure further provides that the Federal commission shall co-operate with the States and other Federal agencies, that there shall be no charge on State and municipal power projects, and that industrial plants developing less than 200 h.p. shall not be required to pay a license. On two years' notice in writing the United States would have the right, at the expiration of a license, to take over and operate plants.

Power plants now in operation would not come under provision of the bill.

THE EXPRESSION OF DIELETRIC LOSSES IN CABLES

Correction

The following correction should be made on page 56 of the January JOURNAL.

The formula for "A" should be revised as follows:

$$\text{where } A = \log_{10}\left[\frac{d\sqrt{3}}{a} \quad \frac{b^2 - d^2}{\sqrt{b^4 + b^2\ d^2 + d^4}}\right]$$

Three lines below should be changed to read as follows:

$d = 1/\sqrt{3}$ of distance between centers of conductors.

Notes on the Synchronous Commutator

BY J. B. WHITEHEAD

Professor of Electrical Engineering, Johns Hopkins University

AND

T. ISSHIKI

Engineer, Shibaura Engineering Works

In the use of the synchronous commutator in series connection as a suppressor, serious errors may arise due to relatively small amounts of capacity in the commutator and galvanometer circuits. The magnitude of these errors is studied for a number of different connections, and methods for eliminating them are pointed out. A number of wave forms are given, indicating the nature of the errors.

Used as a shunt suppressor the commutator is far more reliable and this method of connection is always to be preferred.

An appendix gives a theoretical analysis of two cases investigated and shows a close agreement with the experimental observations.

In certain methods of measurement of the crest values of high alternating voltages it is necessary to measure accurately the average values of very small alternating currents. One of the commonest of these methods is that in which a condenser, in series with a low resistance, is placed across the voltage and the voltage drop over the resistance, due to the charging current, measured on an instrument of D'Arsonval type with high series resistance, through the use of either a synchronous commutator or rectifying vacuum tubes.

In these methods, if the commutator is used the instrument receives either a rectified alternating current, made up of both half waves, or a uni-directional pulsating current, made up of alternate half waves with the intermediate opposite half waves cut out either by opening the circuit (series commutator), or by short-circuiting the instrument (shunt commutator). When the commutator is used so as to eliminate alternate half waves, F. Bedell[1] has called it a *suppressor*. If the rectifying vacuum tube is used the current in the measuring instrument is always pulsating with alternate half waves cut out. In any of the above mentioned cases the instrument reads the average current in terms of its calibration by continuous current. For the cases in which the current is pulsating, the instrument reading is multiplied by two to obtain the average value of the condenser charging current, it being assumed that the active half wave of charging current is accurately reproduced in the instrument and that in the intervening half wave interruption no current flows in the instrument.[2]

Measurements of crest value by these methods are probably the best so far obtained, but apparently no special effort has been made to put them on a precision basis. When a sensitive galvanometer is used, the pulsating character of the current raises questions as to the influence of capacitance and reactance in the instrument circuit, and as to the validity of the factor 2 mentioned above. The observations recorded below show that under certain circuit conditions serious errors may arise.

The Apparatus

The commutator used in the experiments was six inches in diameter and had six brass segments ½-in. wide, insulated from each other by 1/32-in. built-up mica, and from the hub by standard V-shaped commutator bushings. Two brass rings, 6-in. in diameter and ½-in. wide, were mounted one on each side of the central commutator segments and insulated from them by intermediate bakelite rings. Screws holding the outer brass rings in place, passed through the bakelite connecting the outside continuous rings to opposite sets of three alternate commutator segments. The commutator was mounted on the end of the shaft of the 6-pole generator. Four brushes of 1/64-in. thick spring bronze, stiffened with backings of steel spring, were carried on a graduated bakelite disc arranged for complete rotation about the axis and clamping in any position. The commutator was machine-constructed throughout. It was frequently tested for insulation and showed throughout a resistance of the order 10^3 megohms.

The 6-pole generator was single phase and had a capacity of 5 kw. at 60 cycles and 120 volts. It was driven by an adjustable-speed continuous-current shunt motor, permitting a range of frequency from 20 to 90 cycles. The armature was surface wound, giving a smooth wave approximating closely to sine shape.

Two D'Arsonval galvanometers were used, both of suspension type, read by telescope and scale. One, No. 24515, had a resistance of 115 ohms, a sensitivity of 40 megohms, an undamped period of 9.5 seconds, and a critical damping resistance of 560 ohms. The corresponding figures for the other galvanometer, No. 23518, were 1680 ohms, 1280 megohms, 22 seconds, and 3400 ohms. The sensitivities for the two instruments when critically damped therefore were 33 and 420 megohms, respectively.

To be presented at the 8th Midwinter Convention of the A. I. E. E., New York, February 20, 1920.

Commutator as Series Suppressor

Obviously the most rigid test of the circuit and instrument for pulsating current is to apply a continuous electromotive force, chopping it up into alternate intervals at full value and zero value by means of the series commutator, as indicated in full lines in Fig. 1. The complete interruption of the current and the sudden application of the full electromotive force accentuate any conditions tending to upset the perfect rectangular half wave alternating with a half period of complete interruption. The test of this performance is the ratio of the readings of the galvanometer with commutator at standstill and when running. This ratio should be 2. This arrangement uses only two brushes and will be spoken of as the series connection of the commutator.

Fig. 1 shows the commutator in series connection; that is, as a simple make and break device in the circuit containing a single dry cell E, resistance $R = 10^6$ ohms and $r = 10^4$ ohms and the galvanometer shunted with its critical damping resistance. Several different types of resistance were used for R; a series of carbon lightning arrester rods aggregating 200,000 ohms, a series

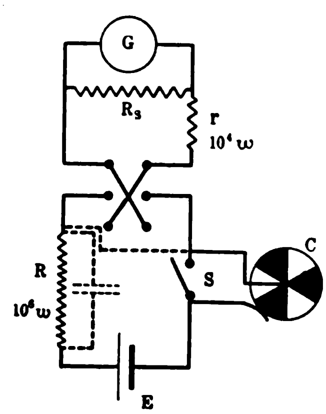

Fig. 1—Commutator Connected as Series Suppressor

of so-called "lavite" units aggregating 10^6 ohms, and a precision set of non-inductive, capacity-free, manganin units aggregating 10^6 ohms, in which the wire was wound in single layers on thin micanite plates, suspended on glass rods.

A number of observations were made at different speeds of the commutator C, and with S open and closed, corresponding to running and standstill conditions for C. In every case it was found that the ratio of galvanometer deflections for running and standstill was greater than 0.5. A typical set of observations is shown in Table I and plotted in Fig. 2 as curve No. 2. The speed, in terms of the frequency of the generator, is plotted as abscissa, and the ratio of running to standstill deflection of the galvanometer as ordinate.

The increase of the ratio of running to standstill deflections with the frequency obviously suggests the presence of capacity as a disturbing element. This was confirmed by a rearrangement of the apparatus and connections so as to reduce the capacity in circuit. In Fig. 2, curve No. 1, the resistance R was connected into the circuit over a pair of leads consisting of twisted lamp cord about 100-ft. long and having a capacity of about 0.005 microfarads. In curve No. 2, R^1 was a small compact resistance of the same

TABLE I

Speed cycles	Deflection of galvanometer						
	Running			Standstill			Running / Standstill
	left	right	mean	left	right	mean	
23.5	5.6	5.59	5.595	10.22	10.32	10.27	0.545
41	5.8	5.80	5.80	10.22	10.32	10.27	0.565
59	5.95	5.95	5.95	10.22	10.32	10.27	0.580
81	6.2	6.18	6.19	10.22	10.32	10.27	0.603

value as that pertaining to curve No. 1, but connected to the circuit with short leads. The remaining curves showing decreasing departure of the ratio of running to standstill values from 0.5, show the successive improvements resulting from shortening and separating the various connections of Fig. 1. It should be noticed, however, that under the very best conditions

of short, well-separated connections, with the arrangement of Fig. 1, there is always an error in assuming a ratio of running to standstill deflections of 0.5 and this error increases with the frequency.

By means of the method of connection shown in Fig. 3, it was found that in the half wave in which the circuit is closed by C, the current is greater than the standstill value, and during the half wave in which the circuit is opened by C there is still some current in the positive direction. B is a second com-

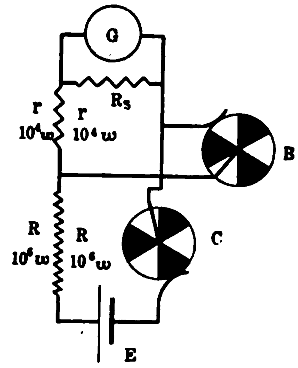

Fig. 3—Series and Shunt Suppressors in the Same Circuits

mutator on the same shaft with C and is connected in shunt with the galvanometer, as indicated. By proper setting of the brushes of B it is a simple matter to short-circuit the galvanometer for the periods of opening or closing by C, and thus read the current for the opposite half wave. For example, at standstill, with B open and C closed, the galvanometer reading was 9.9; when running and with B set for reading during closed C and open C, respectively, the readings were as follows:

TABLE II

Speed cycles	Closed C	Open C
23	5.78	1.1
41	6.15	1.38
60	6.5	1.7
77	6.7	....
80	....	1.9

Since in each case the galvanometer is receiving current only one-half the time, the readings must be multiplied by 2 to obtain the full values. They show therefore that during the half wave of closed C the current is greater than 9.9, and during the half wave of open C the current is greater than 0. Moreover the excess of current value increases with the frequency.

A further study of the influence of capacity with the connection of Fig. 1 was made by inserting additional capacity in shunt to the resistance R, between the commutator leads, and between commutator segments. In the upper part of Fig. 4 curves are plotted showing the variation of the ratio of running to standstill deflection with the frequency for series commutator and for different values of capacity connected in shunt to the resistance R. The lower half of Fig. 4 gives curves taken with the commutator in shunt connection. These curves will be referred to below. Similar curves are obtained when the capacity is connected between the leads to the commutator.

In Fig. 5 the two lower curves were taken at 60 cycles with various values of capacity connected be-

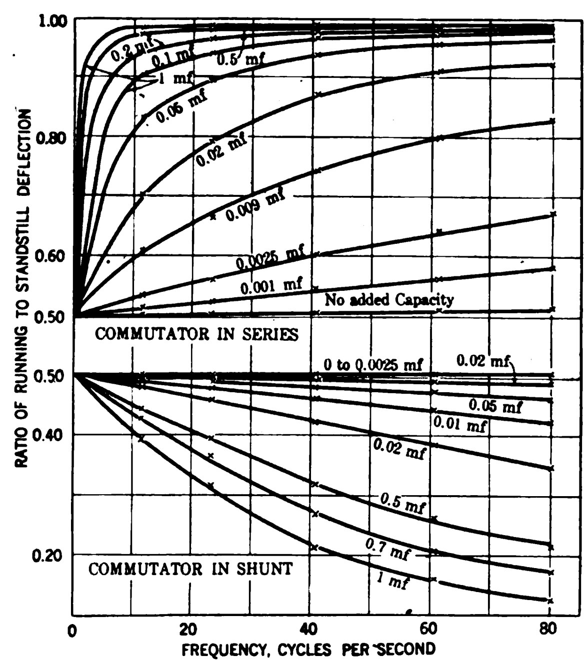

Fig. 4—Influence of Capacity in Shunt to 10⁶ Ohm Resistance upon Ratio of Running to Standstill Deflection. Brush Narrower than Insulation between Segments

tween the opposite sets of segments of the commutator. This connection is made by connecting the capacity in parallel with the two outer collector rings of the commutator. Curve No. 2 is taken with a brush which is thicker than the insulation between segments and curve No. 3 is taken with a brush which is thinner than the insulation between segments. It is noteworthy that the use of the thick brush, short-circuiting as it does the capacity shunted around the commutator and thus discharging the capacity, is the cause of a wide error in the value of the ratio of running to standstill deflections. Curve No. 1 shows that the effect of adding capacity between commutator leads is similar to that of adding capacity between the terminals of R.

In view of the foregoing results, it appeared of interest to study the wave form of the current in the galvanometer. The current values being too small for the oscillograph, the method shown in Fig. 6 was adopted. C is the rectifying commutator already described arranged for series connection, that is, using only two brushes and operating as a half cycle make and break. Switching is also provided so that C may be arranged in shunt connection or cut out entirely. D is a metal disc also mounted on the generator shaft and equipped with three narrow insulating sectors set in its outer surface. Two brushes on D short-circuit the galvanometer, as indicated, during a complete cycle except for the brief interval when the short circuit is interrupted by one of the insulating segments, that is, once in each cycle of make and break. The particular instant in the cycle at which the galvanometer receives current is varied by rotating the brushes on C. The arrangement constitutes a point by point method for studying the current in the circuit of the commutator C.

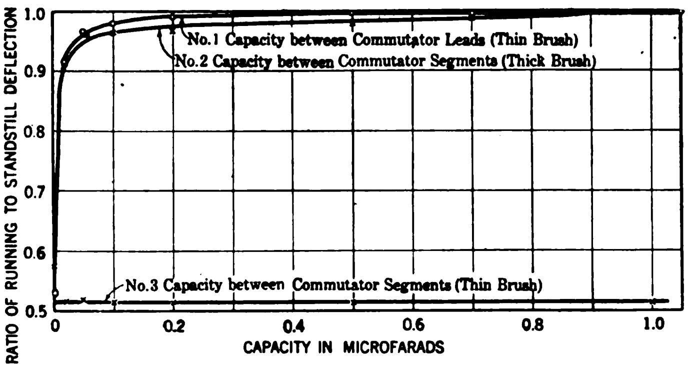

Fig. 5—Influence of Capacity between Commutator Leads and between Commutator Segments upon Ratio of Running to Standstill Deflection. Commutator in Series. 60 Cycles

Observations were taken with C both in series and in shunt. A typical set is given in Table 3 and plotted in Fig. 7. It was found that with D operating and C cut out completely, that is, with steady current in the battery circuit, the deflection of the galvanometer had a slow and irregular variation and usually different values for opposite positions of the reversing switch. These variations were due to thermal electromotive forces or other variable contact conditions at the brushes of D. In order to eliminate this trouble right and left readings of the steady current (C not in circuit) and of the instantaneous current (C in circuit) were taken in quick succession and their mean values used. The wave form is obtained by taking for each brush setting the ratio of the mean of the instantaneous readings to the mean of the steady readings.

The more interesting results are plotted in the curves of Figs. 7, 8 and 9, showing several forms for both series and shunt connections of the commutator. In the case of Fig. 7 the frequency was 60 cycles and the 1-megohm resistance R and the commutator C had leads consisting of twisted lamp cord 100-ft. and 15-ft. long (capacities about 0.005 and 0.0007 microfarads) respectively, the brush was thinner than the width of the insulating segments in the commutator C. In Fig. 8 the conditions were the same at a frequency 24 cycles, and in the lower curve a brush thicker than the insulating commutator segments was used. In Fig. 9 short separated leads of minimum capacity were used to R, and the 15-ft. twisted leads to C.

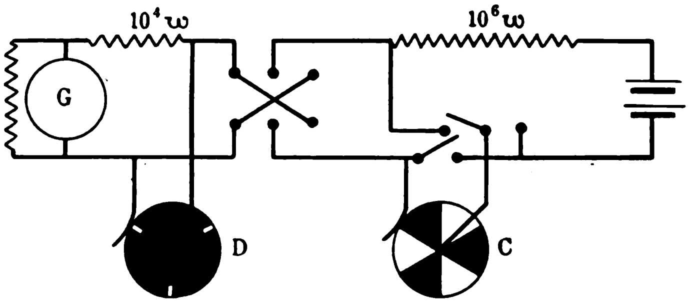

Fig. 6—Connections for Taking Wave Forms of Series and Shunt Suppressors

As already indicated, the results shown in the foregoing figures are due to the capacity located in different parts of the connections. For example, in Fig. 7, during open circuit by the commutator, the capacity of the commutator itself charges as indicated at (a) and C' the capacity around the resistance R discharges

through the resistance. At (*b*) on the instant of closing, the capacity C' charges, giving an excess current through the galvanometer which immediately tends to fall to the value fixed by the resistance R.

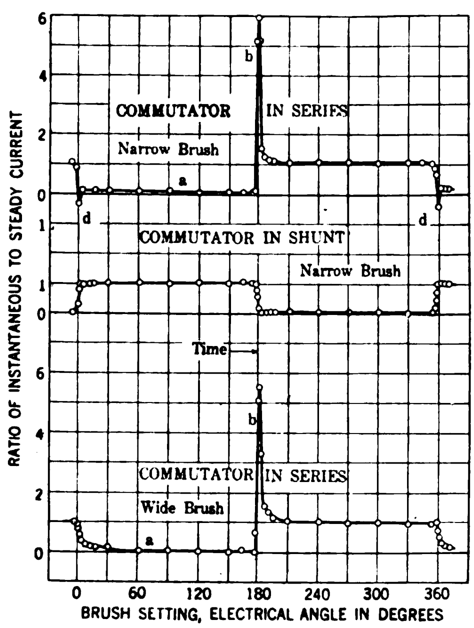

FIG. 8—WAVE FORM OF CURRENT THROUGH GALVANOMETER. 24 CYCLES. ALL LEADS SAME AS FIG. 7

At (*d*) if the brush is narrower than the insulating segment of the commutator, the counter-electromotive forces of the capacities C and C' are in series and therefore greater than the battery electromotive force E; hence, there is momentarily a reverse current after the circuit opens. Then as C' discharges through R the electromotive force falls and the battery charges the capacity of the commutator, resulting in a positive charging current for the interval (a). If the brush on C is wider than the insulating segment, the capacity of C is discharged through the brush and during the following interval of open circuit the charging current of this capacity is higher. (See Fig. 8, lower curve).

When the leads to the commutator contain capacity with either a wide or narrow brush, the capacity discharges through the commutator and not through the galvanometer at each interval of make, and therefore this capacity charges through the galvanometer during each interval of break; hence there is excess current through the galvanometer at each interval of break, resulting in an increase of the ratio of running to standstill conditions. (See curves of Figs. 5, 7, 8, 9).

The effect of capacity between segments in the commutator itself is as follows: This capacity charges during open circuit. If a thick commutator brush is

used, the capacity discharges through the brush at the instant the brush bridges the insulating commutator segment, and hence the capacity charges in each interval of open circuit, giving excess galvanometer current and increased ratio of running to standstill current. If, on the other hand, the commutator brush is narrower than the insulating segment, the capacity retains its charge except for loss due to leakage and hence there is no recharge and no excess galvanometer current after the first charging interval, consequently the ratio of running to standstill current in the galvanometer is independent of the value of the capacity and approximately equal to 0.5. (See curves of Fig. 5).

The apparent errors of the series connected com-

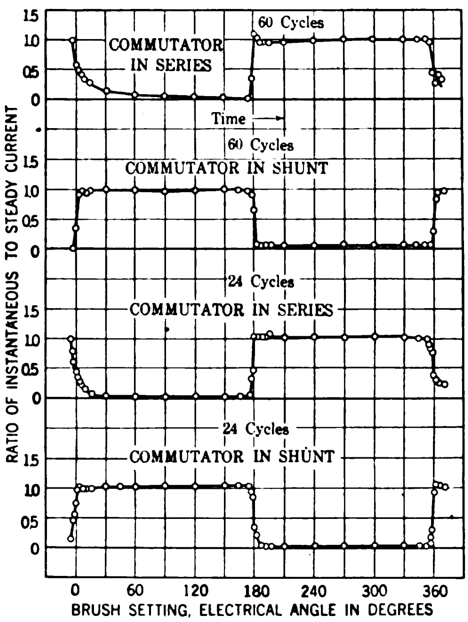

Fig. 9—Wave Form of Current through Galvanometer, Brush Narrower than Insulation between Segments. Leads for 10^6 Ohm Resistance: Short Separated Wires. Leads for Commutator: 15 ft. Twisted Lamp Cord (Capacity about 0.0007 Microfarads)

mutator may be reduced to a minimum or avoided entirely in two ways: First, by any method of connection whereby the current in the resistance R is not interrupted. Two methods of accomplishing this are shown in Figs. 10 and 11. In Fig. 10, by using three brushes on the commutator during the period in which the galvanometer current is interrupted, the current in R is maintained at constant value by means of the resistance R' of value equal to that in the galvanometer circuit. A number of accurate observations with this method of connection at various values of frequency and capacity were made, and the ratio of running to standstill deflection of the galvanometer was very accurately 0.5 throughout, except for the case of large capacity connected between the points (b) and (c). In Fig. 11 the current in R is also constant and the galvanometer may be shunted around either of the resistances r. In a series of experiments with this connection, 120-volts continuous potential was used, and capacity up to 1 microfarad was shunted around both resistances R and r, in order to intensify any disturbances due to charging currents. Both at 24 cycles and 60 cycles the ratio of running to standstill deflection was accurately equal to 0.5 throughout.

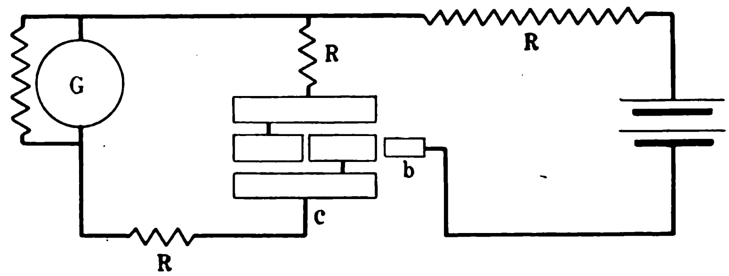

Fig. 10—Connections of Series Suppressor for Eliminating Errors Due to Capacity

A second method for reducing the error in the simple connection of Fig. 1 is a reduction of the value of the resistance R. Using the twisted lamp cord leads mentioned above, to R and C, Fig. 12 shows a series of observations at 60 cycles on the value of the ratio of running to standstill deflections in relation to the value of R. As indicated, when R is equal to 1 megohm the ratio is 0.72 and the current in circuit is 3.1×10^{-6}

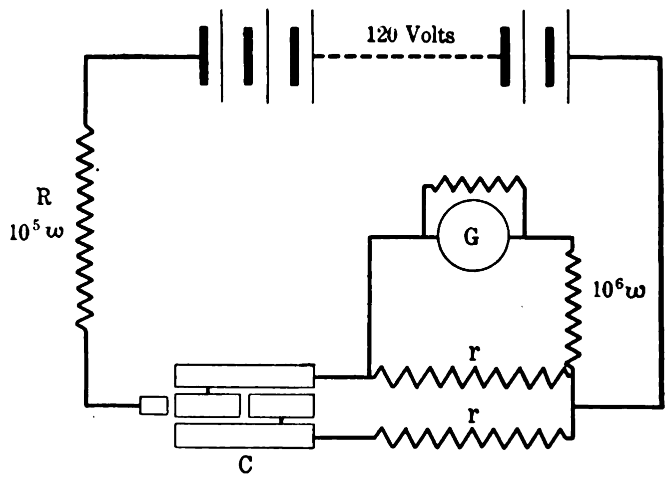

Fig. 11—Connections of Series Suppressor for Eliminating Errors Due to Capacity

amperes. For $R = 5 \times 10^{-4}$ ohms the ratio is 0.51 and the current 6.2×10^{-5} amperes. For $R = 10^4$ and 10^3 ohms, the ratios were found to be 0.501 and 0.4995 respectively. In the last case the current in circuit was approximately 3.1 milliamperes. (See Fig. 12).

Analyses of the series commutator connection for capacity C, shunted around the resistance R and across the commutator leads, are given in an appendix. It is shown that the value of the ratio of instan-

taneous to steady current in the galvanometer for any particular position of the brush setting, as well as the ratio of running to standstill deflections of the galvanometer, are functions only of the product $f\ C\ R$ and of α where f is the frequency and α is the ratio of R to r (see Fig. 1). That is, reductions in the values of frequency, capacity or of the resistance R, all result in a closer approach of the ratio of running to standstill deflections to the value 0.5. Curves are also given showing a close agreement between the observations and the theory.

Commutator Connected as Shunt Suppressor

With the commutator connected in shunt, as indicated by the dotted line in Fig. 1, the errors due to capacity are not so serious as in the series connection. In the shunt connection, since the current through R varies only by the alternate cutting in and out of the relatively small resistance of the galvanometer circuit, the variation of electromotive force at its terminals is correspondingly small. Throughout a number of observations with this method of connection the ratio of running to standstill deflections was very accurately 0.5 even when the ratio R/r was not greater than 10 (values at 23, 40, 60 and 80 cycles all being 0.501). Although the current pulsation in R in this case is relatively great, the low value of R tends to reduce the charging current of any small capacity which may exist. For values of the ratio R/r greater than 100, the current pulsation is small and if the circuit has no capacity, the error is small (values of ratio R/r at the above frequencies being 0.502, 0.501, 0.501 and 0.500).

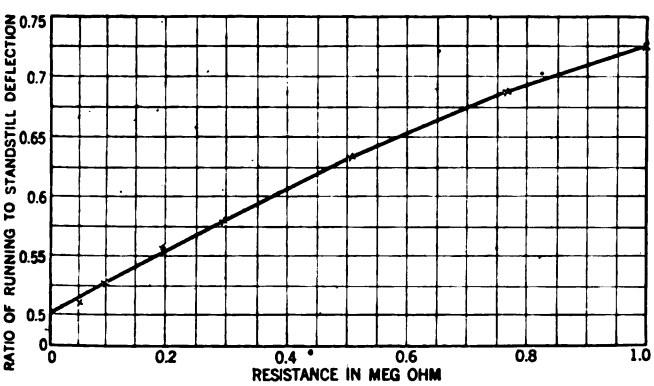

Fig. 12—Effect of Variation of R in Fig. 1 upon Ratio of Running to Standstill Deflections. Commutator in Series. 60 Cycles. Thin Brush

Capacity, however, soon introduces trouble. When located in the leads to the commutator it charges on open commutator and discharges on a closed commutator. Thus during the open period current is shunted from the galvanometer, lowering the ratio of running to standstill deflections. The phenomenon is the same for thin and thick commutator brushes. In a series of observations at 24 cycles, the ratio decreased from 0.504 to 0.298 in increasing the capacity between the leads from 0 to 1 microfarad.

When there is any capacity between the commutator segments, this capacity charges and stays charged without influence on the ratio of running to stand at standstill deflections if the commutator brush is thinner than the insulation between segments. With a thick brush, however, the capacity discharges when the brush bridges the insulating segment and then charges in the position of open commutator, the performance then being as in the case of the foregoing paragraph. The capacity between commutator segments, as measured, was found to be 0.00126 microfarad. In a series of observations the addition of 0.02 microfarad between commutator segments changes the ratio of running to standstill values from 0.498 to 0.488 with still further lowering for increase of capacity.

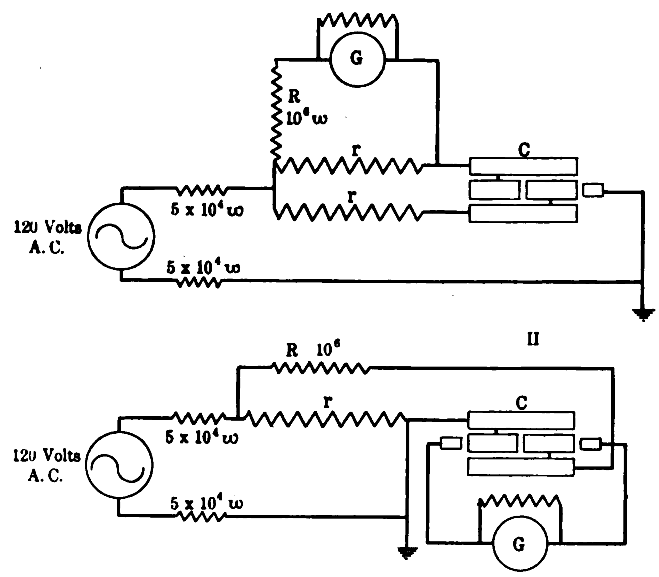

Fig. 13—Series Commutator. Elimination of Electrostatic Unbalancing

When there is capacity in the leads to R on closed commutator, this capacity receives the full battery e.m.f. On open commutator at the instant of opening, the counter e.m.f. of the capacity is equal to that of the battery and no current flows in the galvanometer G. As the capacity discharges through R there is a delay in the rise of current to its full value, thus causing a lowering of the ratio of running to standstill deflections, and in greater amount the greater the capacity shunting R. (See Fig. 7, and curves in the lower half of Fig. 4).

Performance on Alternating Current

The errors arising from the presence of capacity in using the commutator with alternating current are smaller than those that have been described. This is to be expected since on commutation the alternating

TABLE IV

r ohm	Deflection of Galvanometer						
	Full Wave (Fig. 13, I)			Half Wave (Fig. 13, II)			Half wave / Full wave
	left	right	mean	left	right	mean	
1000	3.63	3.69	3.66	1.83	1.83	1.83	0.500
1000*	3.66	3.70	3.68	1.83	1.83	1.83	0.497

2000*	7.30	7.32	7.31	3.63	3.63	3.63	0.497

current tends to rise gradually from the zero value and not abruptly as in the case of the pulsating continuous current. In a number of observations taken with alternating current introduced by means of a transformer located in place of the battery of Fig. 1 and with the commutator connected in both series and shunt for reading alternate half waves and also for the reading of full rectification by means of the addition of two more brushes to the commutator in the usual manner, the ratios were found to be very accurately 0.5 under *properly selected* conditions. However, even with careful elimination of capacity from all connections considerable errors may be introduced by reason of unsymmetrical electro-static relation of the various parts of the circuit. For example, introducing alternating e.m.f. in place of the battery in Fig. 11 for obtaining alternate half waves in the galvanometer, and then by a simple change of connections sending the complete rectified alternating

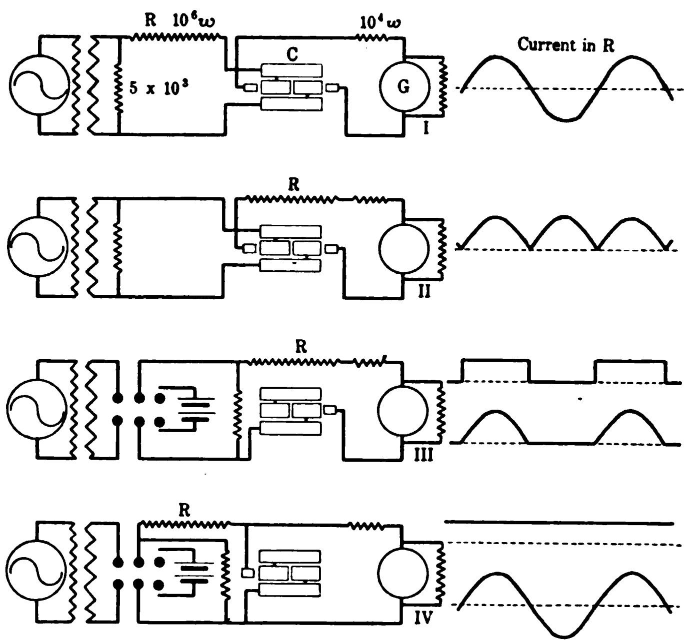

FIG. 14—SERIES AND SHUNT COMMUTATORS. COMPARISON OF VARIOUS TYPES OF PULSATING CURRENT IN SERIES RESISTANCE

current through *G*, the ratio of half wave to full wave deflections was found to be 0.511. When, however, the circuit was rearranged, as shown in Fig. 13, so as

to divide the resistance R between the two halves of the circuit, the results of Table IV are obtained, showing that the ratio for half wave to full wave deflection of the galvanometer is very close to 0.5. In these circumstances capacity (up to one microfarad) may be shunted to r or R without affecting the ratio 0.5 of half wave to full wave. The position of the brushes was usually set for maximum deflection, although the method of setting for zero deflection and then shifting 90 electrical degrees was sometimes used.

For further study of the influence of capacity, the connections shown in Fig. 14 were used. Connection *I* gives complete rectification and normal alternating current through the resistance R. Connection *II* gives complete rectification with pulsating current through R. Connection *III* is the simple series connection for both R and the galvanometer and therefore has pulsating current in R with alternate half waves eliminated. Connection *IV* is ordinary shunt connection with normal alternating current in R. In all cases current is introduced into the circuit through a step-down transformer giving very low voltage in the galvanometer circuit.

Table V gives the readings taken with each of the methods of connections shown in Fig. 14, for various positions of the commutator brushes. The results are plotted in Fig. 15. It is of interest to note that in this case in which capacity has been eliminated as far as possible, the ratio of the half wave to the full wave deflection is very closely equal to 0.5 for all positions of brushes, independent of the method of connection.

Fig. 16 shows the effect of shunting the resistance R with 0.02 microfarad. In this case the ratio of the maximum value for connection *IV* to the maximum

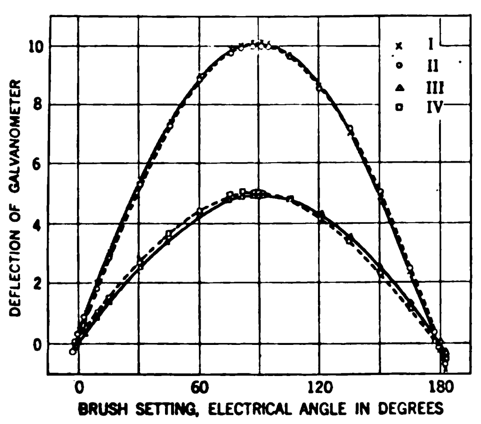

FIG. 15—DEFLECTION OF GALVANOMETER FOR VARIOUS POSITIONS OF BRUSHES, CONNECTION FIG. 14. CAPACITY ELIMINATED AS FAR AS POSSIBLE

value for connection *I* is 0.498, thus indicating the reliability of the shunt method of connection. On the other hand, the ratio of the maximum value for connection *III* to the maximum value for connection *I* is only 0.105, showing the unreliability of the series commutator connection when the circuit contains any capacity.

In order to compare the disturbance introduced in the series connection by the presence of capacity when using continuous and alternating currents, observations were taken with very small values of capacity by making the connections to R with two lengths of

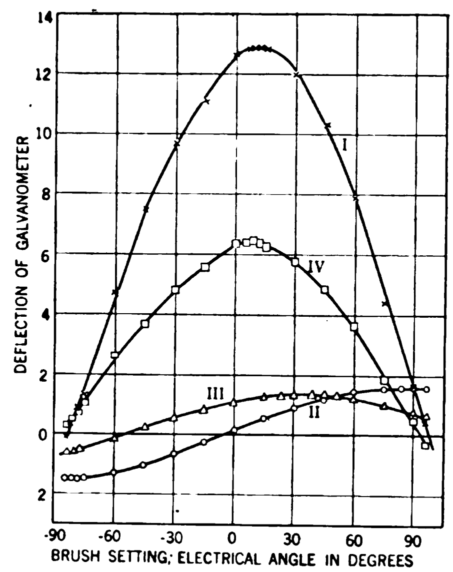

FIG. 16—DEFLECTION OF GALVANOMETER FOR VARIOUS POSITIONS OF BRUSHES, CONNECTION FIG. 14. RESISTANCE R SHUNTED BY 0.02 MICROFARAD CAPACITY

twisted lamp cord, introducing capacities of 0.002 and 0.006 microfarads respectively. The observations were taken at 60 cycles and the results are given in Table 6. The upper line gives the ratios of half wave to full wave for alternating current, as determined by connections *III* and *II*, respectively, and the lower line the ratio of running to standstill deflection using continuous current.

TABLE VI
INFLUENCE OF CAPACITY ON HALF WAVE READING

Capacity m.f.	0	0.002	0.006	0.02
A.C.	0.496	0.509	0.616	0.849
D.C.	0.51	0.602	0.741	0.907

It will be noticed, while that generally in the same direction, the disturbing effect of the capacity is less for alternating than for continuous current.

DISCUSSION

Small alternating currents may be measured by means of a synchronous commutator with a high sensitivity D'Arsonval galvanometer. The combination

may be placed directly in the circuit, or perferably may be used in conjunction with high non-inductive series resistance to measure the voltage drop over a relatively low non-inductive resistance carrying the current to be measured.

The commutator may be connected in series with the galvanometer so as to open and close its circuit during alternating half waves, in shunt so as to short-circuit the galvanometer during alternate half`waves, or it may be connected so as to completely rectify the alternating wave, thus making use of both half waves. In the two former methods of connection the commutator is spoken of as a suppressor.

In all methods of connection under steady conditions the galvanometer reads the average value of current passing through it in terms of its continuous current calibration. With either type of suppressor, since the instrument receives current during only one-half cycle, the value of the reading is multiplied by two in order to obtain the average value of the alternating current as based on the continuous current calibration.

Using the series suppressor, serious errors may arise due to relatively small values of capacity in the resistances and connections of the galvanometer and commutator circuit. Owing to the interruption of the circuit the capacity charges and discharges in such a way as to increase the instrument current during the closed half cycle and to raise it above zero value in the open half cycle. This source of error may be avoided if during the open half cycle the source of alternating current or electromotive force is kept closed by a second circuit equivalent to that of the galvanometer. This may be done by using the opposite segments of the commutator. (See Fig. 10).

The shunt suppressor is far more reliable and with careful elimination of capacity from the galvanometer circuit the errors may be reduced to negligible values.

If it is desired to use the series suppressor the circuit conditions may be tested by taking the ratio of the deflections due to the pulsating current, consisting of alternating half waves, and that due to the completely rectified alternating current by means of connections similar to those in Fig. 14. This ratio should be 0.5. This test should be followed by one applying a continuous e.m.f. with the commutator connected as either a series or a shunt suppressor. The test lies in the ratio of the running to standstill deflections of the galvanometer. This ratio should be 0.5. For the simple series suppressor the value will be always higher than 0.5 unless an auxiliary circuit is used. With the shunt suppressor the value 0.5 may be very closely reached.

In using rectifying vacuum tubes in place of a commutator, two tubes and two resistances must be placed in the alternating circuit. The voltage drop over either resistance may be used for measuring the current. In this case the e.m.f. applied to the galvanometer is the pulsating unidirectional e.m.f. due to alternate half waves. Since no commutator is used, the galvanometer circuit with its series resistance is closed at all times and the presence of capacity introduces no error.

Following is a summary of the conclusions from the tests:

(1) In the use of the synchronous commutator as a series suppressor, serious errors may arise due to relatively small amounts of capacity in the commutator and galvanometer circuits.

(2) Used as a shunt suppressor the commutator is far more reliable and this method of connection is always to be preferred.

(3) The galvanometer should be calibrated with continuous current with the commutator both at standstill and running as an ordinary make and break. If the ratio of these two readings is 2, the circuit cont ditions will introduce no error with alternating currenr.

(4) Several sources of error due to the commutato- are eliminated by the use of vacuum tube rectifiers.

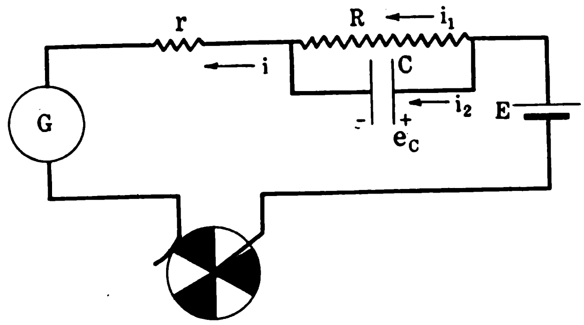

FIG. 17

(5) A number of wave forms of alternating current of very low value are given.

APPENDIX

The following mathematical analysis of the case of the series suppressor as described in the paper gives results in close agreement with those observed.

I. Series suppressor in which the high resistance R is shunted by capacity C and continuous electromotive force E applied. No other capacity in circuit.

Referring to Fig. 17, let i, i_1 and i_2 be the instantaneous currents through galvanometer, R, and C (charging current) respectively, and e_c the instantaneous value of the voltage over C, and let their positive directions be those shown by arrows.

Consider the interval (half cycle) during which the circuit is closed by the commutator. Let us call this interval "closed half cycle". During this half cycle C is charged.

We have

$$i r + i_1 R = E \tag{1}$$

$$i_1 R = e_c = 1/C \int i_2 \, dt \tag{2}$$

$$i_1 + i_2 = i \tag{3}$$

Eliminating i and i_2 from these equations we obtain

$$\frac{d i_1}{dt} + \frac{g}{C} i_1 = \frac{E}{C R r} \tag{4}$$

where $$g = \frac{R + r}{R r} = \frac{1}{R} + \frac{1}{r}$$

The solution of this differential equation is

$$i_1 = A \epsilon^{-\frac{g}{C} t} + \frac{E}{R + r} \tag{6}$$

where A is an integration constant to be determined by boundary conditions.

From (2) and (6)

$$e_c = A R \epsilon^{-\frac{g}{C} t} + E \frac{R}{R + r}$$

If we take the instant of the closing of the circuit as $t = 0, t = \dfrac{1}{f}$ at the instant of opening, f being the frequency, and the value of e_c at these two instants are respectively

$$|e_c|_{t=0} = A R + \frac{E}{R + r} \tag{7}$$

$$|e_c|_{t=\frac{1}{2f}} = A R \epsilon^{-\frac{g}{2fC}} + E \frac{R}{R + r} \tag{8}$$

Next consider the interval (half cycle) during which the circuit is open. Let us call this interval "Open half cycle."

During this half cycle the charge of C discharges through R and the equation of the circuit is

$$\frac{d e_c}{dt} + \frac{e_c}{C R} = 0 \tag{9}$$

the solution of this equation is

$$e_c = A' \epsilon^{-\frac{t}{CR}}$$

where A is an integration constant to be determined by boundary conditions.

If we take the instant of the opening as $t = 0$, the instant of the closing is $t = \dfrac{1}{2f}$ and the values of e_c at two instants are respectively

$$|e_c|_{t=0} = A' \tag{10}$$

$$|e_c|_{t=\frac{1}{2f}} = A' \epsilon^{-\frac{1}{2fCR}} \tag{11}$$

After the steady state of the circuit is established, the values of $|e_c|_{t=0}$ and $|e_c|_{t=\frac{1}{2f}}$ of the closed half cycle must be equal to the values of $|e_c|_{t=\frac{1}{2f}}$ and $|e_c|_{t=0}$ respectively of the closed half cycle, so that (10) and (11) must be identical with (8) and (7) respectively, *i. e.*,

$$A' = A R \epsilon^{-\frac{g}{2fC}} + E \frac{R}{R + r}$$

and $$A' \epsilon^{-\frac{1}{2fCR}} = A R + \frac{R}{R + r} R$$

Eliminating A' from these two equations, we have

$$A = - \frac{E}{R + r} \frac{1 - \epsilon^{-\frac{1}{2fCR}}}{1 - \epsilon^{-\frac{g + 1/R}{2fC}}}$$

Putting this value of A into (6) and replacing g by $1/R + 1/r$ we have for the value of i_1 during the closed half cycle·

$$i_1 = \frac{E}{R + r} \left\{ 1 - \frac{1 - \epsilon^{-\frac{1}{2fCR}}}{1 - \epsilon^{-\frac{1}{2fC}(2/R + 1/r)}} \epsilon^{-1/C\,(1/R + 1/r) t} \right\} \tag{12}$$

From this equation and (1), we have for the closed half cycle

$$i = \frac{E}{R + r} \left[1 + \frac{R}{r} \frac{1 - \epsilon^{-\frac{1}{2fCR}}}{1 - \epsilon^{-\frac{1}{2fC}(2/R + 1/r)}} \epsilon^{-1/C\,(1/R + 1/r)\,t} \right] \tag{13}$$

If I be the value of steady current through galvanometer or the value of i when there is no interruption of circuit, then

$$I = \frac{E}{R + r}$$

Therefore the ratio of i and I or instantaneous current to steady current through galvanometer for any particular time t during the closed half cycle is

$$\frac{i}{I} = 1 + \frac{R}{r} \frac{1 - \epsilon^{-\frac{1}{2fCR}}}{1 - \epsilon^{-\frac{1}{2fC}(2/R + 1/r)}} \epsilon^{-1/C\,(1/R + 1/r)\,t}$$

$$= 1 + \alpha \frac{1 - \epsilon^{-\frac{1}{2fCR}}}{1 - \epsilon^{-\frac{1}{2fCR}(2 + \alpha)}} \epsilon^{-\frac{1}{2fCR}(1 + \alpha)\,2ft} \tag{14}$$

where $\alpha = R/r$

If we denote the time by degrees of the electrical angle D,

$$t = \frac{1}{2f} \frac{D}{180}$$

Putting this value of t into (**14**) we have

$$\frac{i}{I} = 1 + \alpha\, \frac{1 - \epsilon^{-\frac{1}{2fCR}}}{1 - \epsilon^{-\frac{1}{2fCR}(2+\alpha)}}\, \epsilon^{-\frac{1}{2fCR}(1+\alpha)\frac{D}{180}} \qquad (15)$$

This equation gives the ratio of instantaneous to steady current through galvanometer for any particular

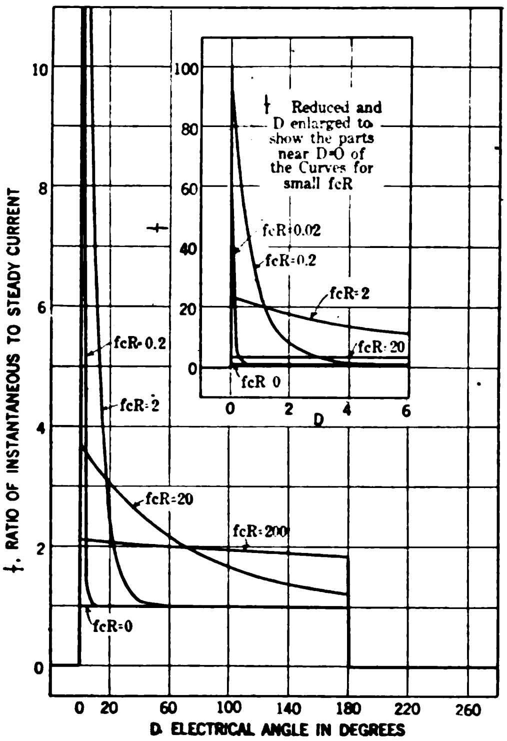

FIG. 18—WAVE FORM OF CURRENT THROUGH GALVANOMETER, R SHUNTED BY C, COMMUTATOR IN SERIES. CALCULATED BY EQUHTION (15.) $\alpha = R/r = 100$.

position of brush during closed half cycle. The value of this ratio for the open half cycle is, of course, zero.

This equation shows that i/I for any particular value of D is function only of $f\,C\,R$ and α.

In Fig. 18 curves between D and i/I computed from equation (**15**) for $f\,C\,R = 0.02, 0.2, 2, 20$ and 200 farad ohm sec.$^{-1}$ and $\alpha = 100$ are given. Corresponding curves as observed are given in Figs. 7 and 8.

The ratio of mean value of i during one cycle to steady current I, or the ratio of running to standstill deflection, S, is as follows:

$$S = \int_0^{1/2f} \frac{i\,d\,t}{I\,1/f}$$

$$= f\int_0^{1/2f} \left[1 + \alpha\, \frac{1 - \epsilon^{-\frac{1}{2fCR}}}{1 - \epsilon^{-\frac{1}{2fCR}(2+\alpha)}}\, \epsilon^{-\frac{1}{2fCR}(1+\alpha)2ft}\right]dt$$

by (**14**)

$$\therefore S = \frac{1}{2}\,\frac{f\,C\,R}{1 + 1/\alpha}\,\frac{\left(1 - \epsilon^{-\frac{1}{2fCR}}\right)\left\{1 - \epsilon^{-\frac{1}{2fCR}(1+\alpha)}\right\}}{1 - \epsilon^{-\frac{1}{2fCR}(2+\alpha)}} \qquad (16)$$

It is seen from equation (**16**) S is also a function only of $f\,C\,R$ and α.

Fig. 19 shows the close agreement between the observations and theory, the drawn curve shows the values

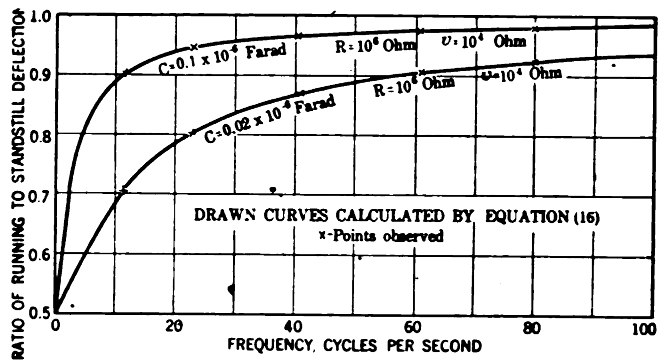

FIG. 19—CURVES BETWEEN FREQUENCY AND RATIO OF RUNNING TO STANDSTILL DEFLECTION. COMMUTATOR IN SERIES

calculated by formula (**16**) and the points marked are those taken from Fig. 4, the results of observation. The values of capacity are 0.02, and 0.2 microfarad which is so large that the capacity between commutator segments does not cause appreciable error.

II. A similar analysis shows that capacity between the leads to the commutator has very closely the same effect as capacity in shunt to R; see Figs. 4 and 5.

PICTURES AT THE SEA'S BOTTOM

Details of the method by which a remarkable photograph of the wrecked Laurentic was taken at the bottom of the Atlantic Ocean, off the Donegal coast, are given in a recent issue of *The London Times*. The camera was inclosed in a water-tight iron tank, tested to stand pressure twenty fathoms deep in water, and fitted with a vessel's porthole glass. A diver took it down, and electric bulbs were lowered from the Admiralty salvage steamship to provide light for the picture. After exposure of an hour and a half it was found that an admirable photograph of the wreck had been obtained. The experiment is regarded as a unique instance of successful deep-sea photography.

It is announced that the world's greatest radio station, with aerials swung upon eight 900-ft. steel towers, was completed at Bordeaux by the United States and will be in operation next Spring.

The Accuracy of Commercial Electrical Measurements

BY H. B. BROOKS

Physicist, U. S. Bureau of Standards

MEASUREMENT runs through the whole structure of engineering. A sufficient degree of maintained accuracy of measurement is essential. Uniform and logical guarantees or statements of accuracy should be used.

Maintained accuracy requires that instruments of the most suitable operating principle be procured from a competent and experienced maker, and be correctly installed and properly used, maintained and tested. These points are discussed in detail. The advantages of uniform wattmeter scales and square-law voltmeter scales are given, with experimental data.

The accuracies stated or guaranteed by American makers range from 2 per cent of full scale value in small switchboard instruments up to 0.1 per cent in laboratory standard instruments.

Electrical instruments have relatively delicate parts and small operating forces, and must be carefully handled if accuracy is required. They should not be overloaded nor exposed to strong magnetic fields.

The effect of room temperature changes on the accuracy varies from nearly 0.4 per cent per degree cent. in millivoltmeters having the circuit almost entirely of copper to a practically negligible value in the moving iron ammeter and in properly compensated d-c. voltmeters and electrodynamic wattmeters. Self-heating of instruments will cause errors unless suitable ventilation is provided.

Stray magnetic fields affect the accuracy of instrument readings, in some types to a serious extent. Induction and hot-wire instruments are only slightly affected. Methods of eliminating errors from this source are given, and curves showing the magnitude of the errors (up to 1.5 per cent) in d-c. instruments due to stray fields from neighboring instruments. Modern American practise is to surround the operating systems of electrodynamic instruments with a soft-iron shield to protect them from stray field. An unshielded electrodynamic voltmeter or wattmeter may be used to determine the strength of the field at any point.

Errors may arise from electrostatic forces acting on the moving parts of instruments. Various ways are described and means of obviating the trouble are given.

Unbalance in the moving system of instruments introduces errors. Means for checking the balance and for balancing the system are described. Maintenance of balance in service is favored by high torque, light weight, rigidity of construction, and avoidance of excessive temperatures.

Permanent magnets in instruments and meters should have the minimum possible reluctance in the air gap. A formula is given for the minimum relation for satisfactory permanence.

Springs should not have a fiber stress exceeding 600 kg. per cm.[2] Zero shift may be transient or slowly progressive. Zero adjusters are becoming general, but introduce danger of errors unless limited in their action.

Torque-weight ratio in indicating instruments should not be below 0.05 in portable instruments, 0.15 in switchboard instruments (units, g. and g-cm.)

Instruments should be designed with the smallest possible losses compatible with adequate torque. When the losses in instruments need to be taken into account, the method of connection should be such as to minimize the error if losses are not allowed for.

Good connections within instruments are essential. Poor connections are revealed by bridge measurements. Contact keys, spring abutments and scales are important details.

The permanent-magnet moving-coil voltmeter is the standard for d-c. measurements. Commercial instruments are available with full scale deflection as low as 20 millivolts and as high as 15 kilovolts, but both extreme values have limitations.

A voltmeter draws current and disturbs the potential difference which it is desired to measure. By taking a second reading with the voltmeter shunted by a resistance equal to its own, the true potential difference may be found by a simple formula. The "pyrovolter" and the "compensated indicator" accomplish the same result in different ways.

The moving-iron voltmeter seems to have the preference for switchboard use. The electrodynamic voltmeter is better for laboratory work. Hot-wire and thermocouple instruments are necessary for radio frequencies. Low-range a-c. voltmeters take an excessive current, which is often difficult to allow for. A two-range ammeter may be used as a compensated ammeter when such low-range voltmeters are used in parallel with a load.

Voltage (potential) transformers up to 30 kilovolts are tested by the potentiometer method for ratio and phase angle. Above 30 kilovolts the accuracy obtainable falls off, and the ratio cannot be computed accurately from winding data obtained at lower voltages. The "tertiary coil" is not believed by the writer to be a solution of the difficulty. Crest voltage measurements are becoming of increasing importance, and there is reason to believe that the corona voltmeter is an accurate instrument for this purpose.

The permanent-magnet moving-coil ammeter is the standard for all direct-current measurements but dry-cell and automobile work. Self-contained ammeters have no leads to cause trouble, but separate-shunt ammeters are more flexible in use. Shunts should be adjusted to standard drops. Ammeters are regularly listed with full scale value from 600 micro-amperes up to 20,000 amperes.

Abstract of a paper to be presented at the Midwinter Convention of the A. I. E. E., New York, February 20, 1920.

When an ammeter is connected into a circuit, the current previously flowing is altered to an unknown extent by its resistance. By taking a second reading after inserting an added resistance equal to that of the ammeter, the original value of current may be readily found.

Moving-iron ammeters are the most generally used for switchboard work. Above 600 amperes, current transformers must be used. The ratio of the currents varies with frequency, current strength, and the connected impedance (secondary burden). Current transformers of higher quality are required for power or energy measurements. Interconnection of secondaries is undesirable for accurate work.

The electrodynamic wattmeter is the standard instrument for a-c. power measurements. Compensated wattmeters automatically correct for instrument losses, but need to be carefully checked to see that the compensating coil is properly located with respect to the fixed coil. Self-inductance produces an error at low power factors. The usual correction factor is given, also the Drysdale additive correction, which the writer considers superior to the correction factor. Numerical examples are given, using actual wattmeter data. The method of compensating for self inductance by capacity is described and its limitations examined. A correction factor is derived for the effects of both self and mutual inductance, and illustrated by examples. The effect of eddy currents in the fixed parts of the wattmeter is two-fold, one part simply tending to reduce the reading, the other acting in opposition to the self inductance.

Polyphase wattmeters cannot be made as accurate as the corresponding single-phase wattmeters, on account of slight differences in the scale law of the two elements. Polyphase measurements are usually made with the two-wattmeter method. Corrections may in general be made more readily if three wattmeters are used, but for balanced loads there is no advantage in using more than two. The use of instrument transformers with wattmeters requires corrections for the ratio and phase angle errors of the transformers. The phase angles of the transformers may be lumped with those of the wattmeter.

Voltage transformers tested over a period of ten years by the Bureau of Standards showed phase angle errors ranging from 2 min. to 69 min. at no load, —38 min. to + 62 min. at full load. Current transformers should not have phase angles exceeding 1 deg. to 1 deg. 30 min. at 60 cycles, 1 deg. 30 min. to 3 deg. at 25 cycles, both at 0.5 ampere secondary. Good current transformers with small secondary burden will average about one-half the above values.

Some of the principal factors affecting the accuracy of electrical energy measurements are briefly discussed. Accuracy curves of both d-c. and a-c. watthour meters droop at overloads, the former because of heating of the armature by the field coils, the latter because of the braking action of the flux from the current magnet. Change of room temperature by 1 deg. cent. should not affect the accuracy of a good d-c. watthour meter more than 0.1 per cent, and a still smaller amount for the induction watthour meter. Direct-current watthour meters are seriously affected by stray field; induction meters to a very much smaller extent. Both d-c. and a-c. watthour meters run more slowly at higher voltages, the former because of heating of the voltage circuit, the latter because of increased braking by the flux from the voltage magnet.

The induction meter can be made fairly independent of frequency changes at unity power factor or of power factor changes at a fixed frequency, but errors result when both frequency and power factor vary. Changes of wave form may cause errors; values of 3 per cent and 15 per cent are cited.

Ratio and phase-angle errors of instrument transformers affect energy measurements just as they do power measurements, but the watthour meter can be adjusted to correct for an average value of each of these errors.

Portable watthour meters are equivalent to service meters except as to register, connections, and case. They should be carefully handled and frequently checked. The d-c. meter is sensitive to local fields, and should be oriented (by means of a compass) so as to avoid error due to such fields. Portable a-c. watthour meters have much better operating characteristics than the d-c. meters.

Further developments which are desirable are briefly discussed, as follows: The user should have a better understanding of accuracy requirements, and the maker should give more data on the subject, and more definite statements or guarantees of accuracy. All instruments should be marked with a symbol to show the operating principle. There should be an American specification for instrument accuracy similar to the one put out by the British Engineering Standards Committee. Desirable materials include a magnet steel of greater coercive force and spring materials having less elastic fatigue. Voltage transformers for high voltages should be smaller and less expensive, and means for obviating or allowing for electrostatic effects on ratio and phase angle should be found. Current transformers as now made are the most unsatisfactory link in the chain of devices used for metering a-c. energy, and much better ones should be made available, so that meters could be adjusted to be accurate on the secondary energy. Special instruments are needed for plant acceptance tests, which will do for a-c. power what the deflection potentiometer does for direct current and voltage. Radical improvements are needed in the d-c. commutator meter. For important a-c. metering installations a much more accurate meter should be made, even at the expense of much greater weight and cost. To accomplish this, the braking flux due to permanent magnets should be very largely increased, and a very much higher grade of steel should be developed for use in the voltage magnet.

Introductory Remarks on Present Theories of Atomic Structure

BY SAUL DUSHMAN

Research Laboratory, General Electric Company, Schenectady, N. Y.

Introduction

THERE is probably no problem in physics and chemistry at the present time that is of greater interest than that of the structure of the atom. During the past few years especially, a number of the foremost investigators in both physics and chemistry have been speculating upon this problem, and while their views cannot by any means be stated to be in agreement, yet they are of exceeding interest and probably contain in each case an element of the great truth which will probably emerge in the next few years.

It has recently been stated that, "A theory in physics is a policy, not a creed." This is the point of view from which we must regard at the present time all theories of the structure of the atom. In the ultimate analysis, a theory is a generalization that correlates a number of experimentally observed facts. The more numerous the facts "explained" by a theory, the more useful it becomes as a means for the further advancement of scientific knowledge, but it may yet be far from the real explanation of all the phenomena which it is intended to correlate.

In approaching the problem of atomic structure, we must therefore first of all attempt to obtain a perspective, as it were, over the immense number of facts that we know about the atom, and knowing these it may perhaps be possible to draw some conclusions as to the values of the different theories which have been proposed for the structure of the atom. While this problem has, until recently, been attacked almost altogether from the point of view of the physicist, and chemical considerations have been given secondary place, it will simplify the discussion of the subject if we reverse the order in the following remarks and deal with the chemical point of view first.

Periodic Law

Chemical Evidence of Complexity of Atomic Structure. For the chemist, the atom itself has hitherto represented the ultimate unit in the structure of matter in which he was interested, and naturally a large number of observations have accumulated with regard to the properties of the atoms of the different elements. Now the most significant fact about all these elements is that it is possible to arrange them in groups so that the members of any one group are much more alike in physical and chemical properties than any two members from two different groups. The periodic law enunciated by Mendeljeff in 1871 states that the properties of the elements, and the properties and compositions of compounds, vary periodically with the atomic weights of the elements. The arrangement of the elements, based on this law, and including those which have been discovered since the above date, is shown in Fig. 1.

There is probably no series of observations bearing on the question of atomic structure that is of greater importance than those which are embodied in the periodic table of the elements.

When the elements are arranged in order of increasing atomic weight, it is observed that among the first twenty elements, there is a repetition to a large extent of physical and chemical properties at every eighth element. Thus sodium resembles lithium; phosphorus, nitrogen and chlorine, fluorine. Beginning with argon, we have to pass over eighteen elements before we come to an element similar to it, and then we have another group of eighteen before we reach xenon which is the next homologue to krypton and argon. Thus, leaving hydrogen and helium out of consideration for the present, we have two series of eight elements and then two series of eighteen. In the series beginning with xenon, however, there occurs a sort of pleiadic system between cerium and tantalum. All these elements are known as the "rare earths." Most of them are so nearly alike chemically and physically that their separation is a matter of extreme difficulty. Evidently there is some fact connected with the structure of the atom which makes the existence of such a group possible when we get to elements whose atoms are heavier than those of cerium. As the atoms increase in mass, the structure becomes more and more complex and finally we obtain a series of elements whose atoms are capable of spontaneous disintegration and thus form the group of radioactive elements.

When Mendeljeff arranged his elements in order of increasing atomic weight, he found that tellurium and iodine apparently did not follow in the order which they should follow according to their chemical and physical properties. Thus, while iodine is very similar to chlorine and fluorine, and tellurium is similar to oxygen and sulphur, the latter has an atomic weight greater than that of iodine. The same discrepancy occurs in the case of argon and potassium. For a long time it was thought that the discrepancies were due to wrong atomic weight determinations, but innumerable investigations have shown that the values as given in Fig. 1 are accurate to less than one-tenth per cent.

The most significant fact brought out by Mendeljeff's arrangement is the gradual change in valency

Address delivered before a joint meeting of the A. I. E. E. and the Am. Phys. Soc., Philadelphia, Pa., October 10, 1919.

as we pass in each series from the elements of low atomic number to those of higher numbers. The elements of group O are chemically inert; they cannot so on. The elements of the fifth, sixth and seventh groups possess two kinds of valencies. With H they form compounds of the types EH_3, EH_2 and EH

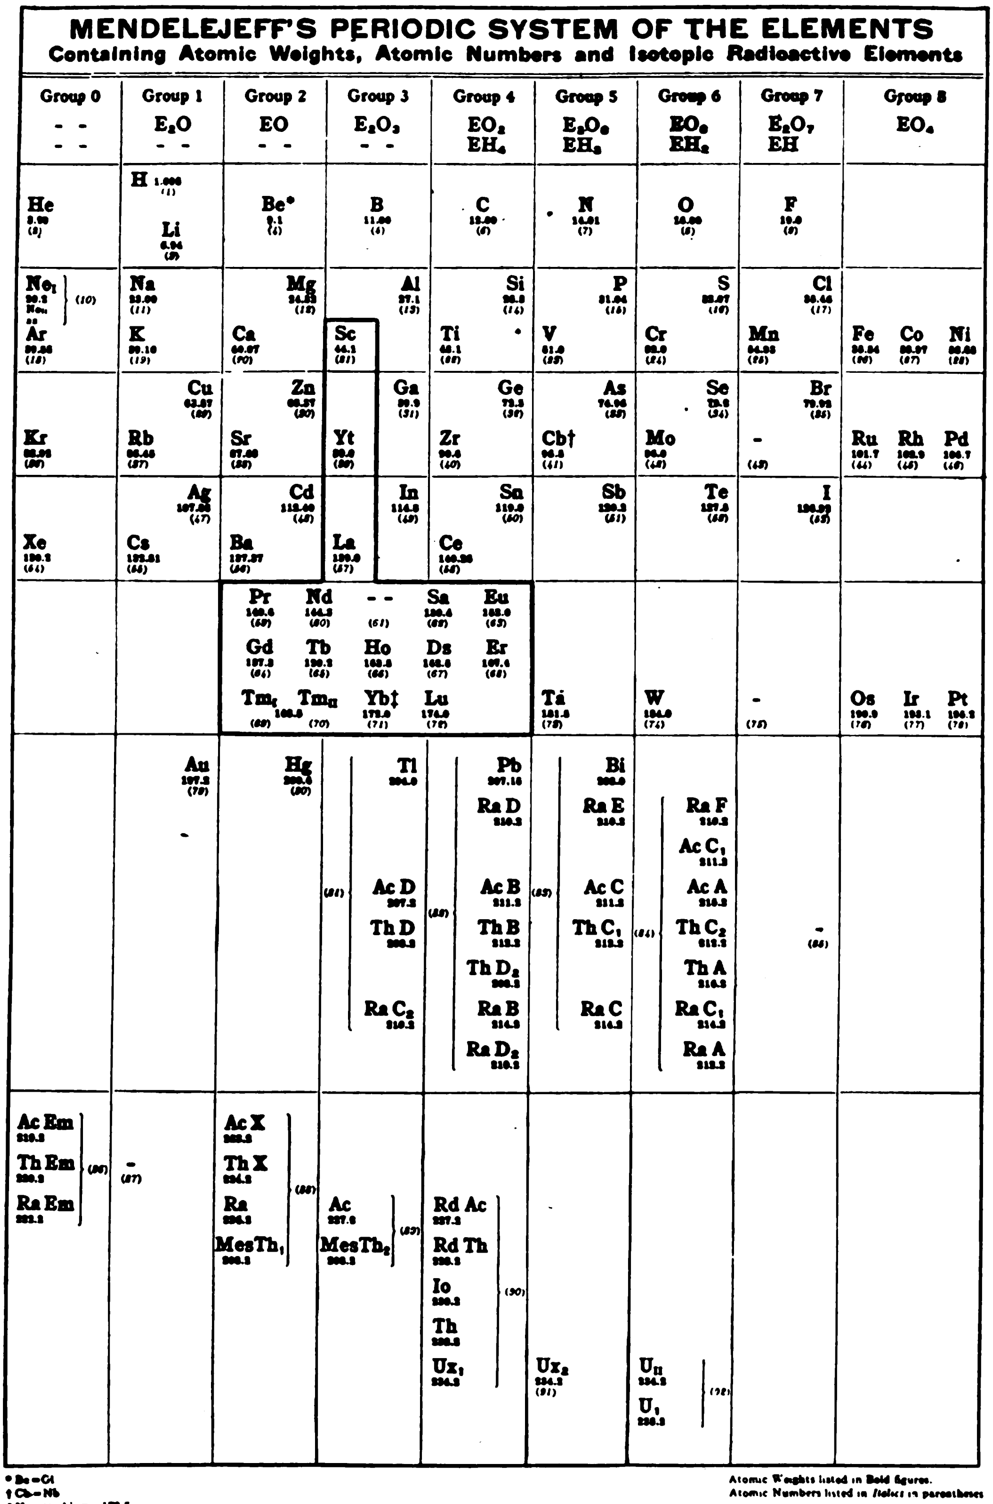

FIG. 1

be made to react with any other elements. They are therefore assigned the valency O. Elements of Group 1 are monovalent (forming compounds of the general type E_2O); those of Group 2 are divalent, and respectively, while with oxygen and more electro-negative elements they are able to form compounds of the types E_2O_5, EO_3 and E_2O_7 respectively.

Not only do the elements exhibit this periodical

recurrence of chemical properties, but they exhibit the same periodic recurrence in most of their physical properties. Fig. 3 illustrates this in the case of the cohesional properties. Those elements which belong to the same group in the periodic table occupy corresponding positions on each of the curves.

When a solution of copper chloride is electrolyzed, copper is deposited at the cathode, that is, the electrode which receives negative electricity, while chlorine is liberated at the anode. Copper is therefore said to be electro-positive, while chlorine is electro-negative. In a Daniel cell, when the plates are joined by a wire, the zinc goes into solution and the copper becomes plated with more copper from the solution. Since the current flows in the wire from the copper to the zinc, we say that the copper is electro-positive with respect to the zinc.

Now it is extremely significant that the most electro-positive elements occur in Group 1, while the most electro-negative ones occur in Group 7; furthermore, in each group the electro-positive property increases with increase in atomic number, so that Cs is much more electro-positive than Li, while I is much less electro-negative than F. Also, the elements of Group 1 combine readily with those of Group 7, the reaction being often quite energetic. The compounds so produced are extremely good electrolytes in aqueous solution and react readily, when in solution, with other salts. As we proceed from Group 1 to Group 7, the electro-positivity decreases, and in Group 5 we find more or less pronounced electro-negative elements, the electro-negativity finally reaching a maximum in Group 7.

Not only do the elements exhibit this periodical recurrence of chemical and electrochemical properties, but they exhibit the same periodic recurrence in most of their physical properties. The Journal of the American Chemical Society in 1915 published a series of curves illustrating cohesional properties of the elements, showing that those elements which belong to the same group in the periodic table occupy corresponding positions on each of the curves.

The Periodic Table thus represents a summary of all the facts that we know about the properties of the chemical elements and their relationships. It is evident that the periodicity exhibited by the elements must be due to some periodicity in the structure of the atom itself. However, the chemist was until very recently not very much interested in pursuing the problem any further, and even if he were interested, the ordinary chemical methods are not adapted for attacking the problem.

Physical Evidences of Complexity of Atomic Structure

The physicist, on the other hand, has found himself confronted all the time by observations which are explicable only by assuming the atom itself to be more or less complex. Naturally, as the facts have accumulated, previous theories have been found to be no longer tenable and these have been either modified or discarded completely. It is impossible in a brief review such as this to deal with all these theories at length, or even to discuss all the fundamental facts, the observation of which have led to the transition from one theory to another. All we can attempt is to review briefly the more prominent facts upon which present views of atomic structure have been based.

The first observations which led physicists to speculate on the structure of the atom were probably those made on the emission and absorption spectra of the different elements. Here we see the atoms emitting and absorbing different types of electromagnetic radiations, and the most obvious suggestion from the physicist's point of view would be that these spectra are due to electric charges executing periodic orbits in the atom.

Atomic Theory of Electricity

The Electron. However, the experiments of Crookes on the electric discharge in gases at very low pressures may be considered as the pioneer investigation in developing our present theory of the constitution of the atom. "He found that, regardless of the nature of the residual gas in the exhausted tube or the nature of the cathode, the rays which are given off at the cathode consist of particles moving in straight lines, that they produce a brilliant glow on phosphorescent subtances, that they exert a mechanical force and generate heat rapidly when intercepted, and that their trajectory is altered by the influence of a magnet."[1]

These discoveries were published in 1879. In 1895 came the discovery of X-rays by Roentgen. When the cathode rays are stopped by matter of any kind, X-rays are produced. The interest in the cathode rays became greater than before, and J. J. Thomson set himself to investigate the nature of the carriers of electricity in these rays. He was able to show that the cathode rays actually consist of *negatively charged* corpuscles (as he designated them), which, starting from the cathode, move with very high velocities in straight lines and produce a vivid fluorescence wherever they strike the glass walls of the tube. Now it was shown a long time ago by Rowland that a charged particle in motion must produce the same effects as are observed in the case of a wire carrying current. In other words, the direction of motion of a charged particle will be effected by magnetic and electrostatic fields, just as a wire carrying current. Furthermore, the magnitude of the effects observed depends upon the ratio of the charge (ϵ) to the mass (m) of the particles and upon their velocity. By observing the amount of de-

1. W. L. Hardin. "The Nature of the Chemical Atom," *Science*, November 10, 1916.

flection suffered by the cathode rays when subjected to magnetic and electrostatic fields, J. J. Thomson concluded that for the negatively charged corpuscles constituting these rays, ϵ/m has a value of about 1.2×10^7 e.m.u. per gm. Later experiments have led to the more accurate value 1.766×10^7. The velocity of the corpuscles was found to vary from 10^7 to 10^9 cm. per sec.

Now let us consider what these results mean. In the case of the electrolysis of a solution of HCl, it requires 96,500 coulombs, or 9650 e.m.u. to liberate 1.008 gm. of hydrogen. The ratio ϵ/m for hydrogen ion ($\overset{+}{H}$) in electrolytes is therefore 9573 e.m.u. per gm. Hence, either the unit electric charge on the corpuscle is almost 2000 times greater than on a hydrogen atom in electrolysis, or the mass of the corpuscle is 2000 times smaller than that of a hydrogen atom.

Now, apart from the evidences obtained by a large number of investigators that the corpuscles constituting the cathode ray beams must have masses much smaller than that of a hydrogen atom, there are definite reasons for believing that the unit electric charge in the cathode ray discharge has the same value as that possessed by the charged hydrogen atom in electrolytic conduction. We must therefore conclude that the mass of the negatively charged corpuscle is

$$\frac{9573}{1.7666 \times 10^7} = \frac{1}{1845}$$

of that of the hydrogen atom.

The most accurate determinations of the charge on an electron are those obtained by Prof. Millikan at the University of Chicago.
According to his measurements

$$\epsilon = 1.591 \times 10^{-20} \text{ e.m.u.}$$

Hence, the mass of the cathode ray corpuscle

$$m = 9.01 \times 10^{-28} \text{ gm.}$$

whereas the mass of a hydrogen atom is

$$M^H = \frac{1.008}{6.062 \times 10^{23}} = 1.663 \times 10^{-24} \text{ gm.}$$

Electron Emission from Hot Bodies

Photo-Electric Effect. The cathode rays of an ordinary discharge tube such as is used for the production of X-rays, is not the only case in which these negatively charged corpuscles, or *electrons*, as they have been designated, are obtained in the free state. O. W. Richardson and others have shown that heated metals emit negatively charged corpuscles with the same value of ϵ/m as that obtained for cathode rays. The number of electrons emitted per unit area of surfaces increases with the temperature according to a relation which has the same form as that which expresses the rate of variation with temperature of the number of molecules given off by a liquid (vaporization). This would indicate that the electrons may be regarded as "evaporating" from a heated metal, and as a matter of fact, the latent heat of vaporization of the electrons has been measured for a number of metals. The interesting fact has been observed that when the metals are arranged in the order of increasing latent heats, we obtain the order of the metals in the ordinary Volta series, the most electropositive metals having the highest values for the latent heat of vaporization.

Electrons are also emitted from all metals under the influence of ultra-violet light. This is the well known photo-electric effect. The more electro-positive the metal, the lower the frequency of the light that is capable of causing photo-electric emission, and in the case of the alkali metals photo-electric currents of considerable magnitude are obtained even when ordinary light is used as a source of illumination.

These facts lead to the conclusion that the atom of all metals must contain electrons as an essential constituent.

Radioactive Phenomena

We must now turn to the consideration of another series of discoveries which has served to indicate the complex structure of the atom.

Shortly after the discovery of X-rays by Roentgen, a number of elements were discovered by Becquerel, Mme. Curie and others which possess the exceedingly interesting property of blackening a photographic plate. Further investigation showed that in general these elements emit three distinct types of radiation, characterized by the following properties:

(1) *β-rays.* From the magnitude of the deflection of these rays in a magnetic field, the conclusion was drawn that they are essentially the same as cathode rays, that is, they consist of streams of electrons, but their velocities are very much greater, so that in a number of cases they approach the velocity of light.

(2) *α-particles.* These are deflected in a magnetic field in the opposite direction to β-rays, and must therefore be *positively* charged. Further investigations have shown that these α-particles have the same mass as the helium atom, and carry *twice* the electric charge possessed by an electron.

(3) *Y-rays.* Recent investigations have led to the conclusion that these are of the same nature as X-rays, that is, electromagnetic radiations, but their wave lengths are much shorter than those of ordinary X-rays.

A study of the behavior of these so-called radioactive elements by Rutherford and Soddy led them to suggest the theory that the atoms of these elements are continually undergoing spontaneous disintegration and forming atoms of elements which possess totally different chemical and physical properties from those of the parent elements.

After a certain average period of existence, which

may range from over 10^9 years, as in the case of uranium (U_1), to less than 1 minute, as in the case of thorium emanation, the atom undergoes a sudden explosion and yields another atom which possesses totally distinct properties. Further investigation has shown that the rate at which these atoms disintegrate is absolutely uninfluenced by any of the factors, such as temperature, pressure, illumination with ultra-violet or X-rays, etc., which are used in controlling the rate of ordinary chemical reactions.

It has been found that each of the radioactive products belongs to one of three well-defined disintegration series whose starting points are uranium, thorium, and actinium respectively. The most noteworthy feature about these products is the fact that individual members of each series appear to be chemically indistinguishable from certain members of the other series. Hence, according to the chemist's definition, they belong to the same element. Owing, however, to the difference in previous history of these atoms, they possess different atomic weights and also differ in period of existence. Soddy, who has drawn attention to these cases, has named these products isotopes, since they occupy the same place in the periodic table. As shown in the table in Fig. 1, there are three other isotopes of thallium, and no less than six isotopes of lead.

These observations point to the conclusion that not only are the atoms of a large number of elements extremely unstable, but also that the atomic weight is not as important a characteristic of any one element as has been previously considered. In fact, the atomic weight of an element is of secondary importance, and there is some other property of the atom which is of much greater significance.

Nuclear Theory of the Structure of the Atom

Light was thrown on this problem by a number of classical investigations in Rutherford's laboratory in 1911. When high velocity electrons or alpha particles are projected at a thin piece of gold foil, they are deflected in such a manner as to indicate that some of them have been subjected to very intense electric fields within the atoms of gold. Furthermore, observations on the angles at which these electrically charged particles are deflected lead to the conclusion that in some cases anyway they must have penetrated to within 10^{-12} cm. from the centre of the atom before being deflected. Now as the average atomic radius is about 10^{-8} cm., this result would indicate that the atom consists of a very intense positive charge of extremely small dimensions (less than 10^{-12} cm.), or nucleus, at the center, and a number of electrons equivalent to this total positive charge situated at different distances from the latter, thus forming, as it were, a miniature solar system. From the measured deflections, Rutherford also concluded that the number of electrons present in any atom is about one-half the atomic weight.

The most signal confirmation of Rutherford's nuclear theory of atomic structure was obtained by Moseley in 1913. As has been mentioned already, X-rays are produced by the projection of high velocity electrons against a metal used as anti-cathode or anode. It was suggested by Laue that these X-rays are really of the same nature as ordinary light waves and the electromagnetic waves used in wireless transmission, but of such extremely short wave-lengths that even the finest diffraction grating cannot be used to measure these, and in order to confirm this theory he thought of making use of a crystal surface in which presumably the atoms are arranged at regular distances. Such a crystal would therefore present a natural grating whose lines instead of being 10^{-4} or 10^{-5} cm. apart are 10^{-8} cm. apart, or 1000 times closer than in the most delicate grating that can be ruled by machine. By this means Laue was able to demonstrate that X-rays are simply an extension of electromagnetic radiation to extremely short wave-lengths about 1000 times smaller than those of ordinary or visible light. Bragg extended Laue's work and showed how the wave-lengths of the X-rays could be measured very accurately.

Now Moseley set himself to investigate the nature of the X-rays emitted by all the elements from aluminum to gold when these are made anti-cathodes in an X-ray tube. With sufficiently high voltages, each element emits two characteristic bands of X-rays which have been designated the *K*- and *L*- radiations respectively. Moseley measured photographically the wave-lengths of the two lines (α- and β-lines) which compose the *K*-radiations of the different elements, and found this remarkable relation: For either the α- or β-radiation, the frequency (velocity of light/wave-length) increases in passing from any one element to one of higher atomic weight, and the order in which the elements can be arranged according to increase in frequency is the same as that which has been found to hold for the elements in the periodic table. Moreover, if N denotes the order of the element in the table ($H = 1$, $He = 2$, and so forth), the frequency of any one line may be expressed by a relation of the form

$$\sqrt{\nu} = a(N - N_0)$$

where a and N_0 are characteristic constants for this radiation.

The fact that such a relation exists which enables us to determine the atomic number, N, for each element and that this atomic number coincides in all cases with the order in which the element must be placed in the Periodic Table in accordance with its physical and chemical properties, must be regarded as one of the most important discoveries in recent years. Not only does it add a new significance to the Periodic Table, but it also throws much light upon the whole problem of atomic structure. For, according to Rutherford the atomic number signifies nothing more or less than the magnitude of the positive charge

on the nucleus of the atom, and hence N corresponds also to the actual number of electrons in the atom, since the number of negative charges in a neutral atom must be equal to the total positive charge.

GENERAL CONCLUSIONS REGARDING ATOMIC STRUCTURE

On the basis of these observations and from what we know of the chemical properties of the elements, we may therefore attempt to draw some conclusions with regard to the structure of the atom itself.

Firstly, the atom must be constituted of a positive nucleus of extremely small dimensions (but approximately equal in mass to the atom itself), and a number of electrons distributed presumably in one or more rings or spherical shells outside the nucleus, the total number of electrons being equal to the positive charge on the latter. Secondly, all the physical and chemical properties of the atom (excepting radioactive and gravitational) are governed solely by the magnitude of this charge on the nucleus (or atomic number).

This conclusion is based on the observations, already mentioned, that in the case of radioactive elements, we may have atoms of different atomic weights, but occupying the same place in the Periodic Table (isotopes), thus indicating that the members while possessing different atomic weights are identical in all their chemical properties and most of their physical properties as well.

Since the disintegration of any atom always yields an atom occupying a different place in the periodic table, we must conclude that the change actually occurs in the nucleus itself. Furthermore, as electrons and alpha particles are emitted during the disintegration, it follows that the nucleus, small as it is, consists of negatively charged corpuscles and helium nuclei, packed close together. How is it possible for positive and negative charges to remain in equilibrium under such conditions? Probably Coulomb's law fails completely for distances as small as those which exist inside the nucleus. It may indeed become reversed; that is, positive and negative charges repel each other at distances which are less than 10^{-13} cm.

Thirdly, in order to explain chemical combination and periodic properties, we must assume that there are two classes of electrons, an inner and outer set. The outer ones are the electrons which are active in chemical combination and conduction of electricity through metals. They are the so-called valency electrons. The number of electrons in this outer set undergoes periodic changes in value as the atomic number increases, and the maximum number of electrons which are stable on the outer surface of the atom is eight, or eighteen, thus accounting for the periodicity of eight and eighteen in Mendeljeff's table.

The outer electrons are also those which are active in the production of ordinary emission spectra. If Lorentz's explanation of the Zeeman effect is right, and it is the only one that explains the phenomenon quantitatively, then we must conclude that the lines visible in ordinary emission spectra are due to the vibration of electrons with frequencies ranging around 10^{15} per second. The fact that these emission spectra are modified by method of excitation and also differ with different compounds, shows that the electrons producing these phenomena are near the surface of the atom and therefore probably the same as the valency electrons.

On the other hand, the inner electrons are unaffected by ordinary methods, but high velocity electrons may stimulate them and thus produce the high-frequency spectra observed by Moseley and others. As pointed out by Kossel[2], the continuity of the K-line spectra for the different elements from the lowest atomic number to the highest, shows that the periodicity observed in the outer electrons does not extend to the innermost.

It will be observed that in drawing these conclusions, we have merely made use of a number of experimental facts, and tried to correlate them by means of a simple physical representation. Such questions as the exact distribution of the electrons, whether in two dimensions or three, whether rotating or stationary, and furthermore the question of the law of force which must subsist between electrons and nucleus in order that the atom shall remain stable—all these problems have not been touched upon at all. It is therefore natural that different theories of atomic structure should diverge in regard to the answers suggested for these questions.

The first atom model which represented a serious attempt to correlate the structure of the atom with its chemical and physical properties was due to Lord Kelvin. It was subsequently extended and developed by J. J. Thomson. Assuming the atom to "consist of concentric rings of negative electrons in a sphere of homogeneous positive electricity of the size of the atom," Thomson was able to show that such a model would be in complete accord with the known periodic properties of the elements.

The observations on scattering of alpha and beta particles mentioned above led Rutherford to propose a nuclear structure such as has already been described, and the work of Moseley, Darwin, and others have confirmed Rutherfords' views.

Now a similar atom model had been suggested some years ago by Nagaoka, but at that time the objection was raised that such an arrangement of electrons rotating around a positively charged center would be dynamically unstable. On the other hand, no such objection could be raised against the model of J. J. Thomson. Thus arose a strange situation in scientific speculations, that the actual observations led to conclusions which were apparently at variance with the classical laws of dynamics.

2. Ann. d. Physik, 49, 229 (1916).

Atom Model of Bohr

The most successful attempt to bridge this difficulty has been made by N. Bohr. In a series of classical papers which appeared in 1913 in the *Philosophical Magazine*, he showed that by introducing certain reasonable assumptions on the nature of the forces between the electrons and the positive nucleus, it is possible to deduce a very definite picture of the structure of atoms and molecules.[3]

After stating the nature of the difference between the atom-models proposed by Thomson and Rutherford, and the objections raised against the latter, Bohr continues as follows:

"The way of considering a problem of this kind has, however, undergone essential alterations in recent years, owing to the development of the theory of energy radiation, and the direct affirmation of the new assumptions introduced in this theory, found by experiments on very different phenomena, such as specific heats, photoelectric effect, Roentgen-rays, etc. The result of the discussion of these questions seems to be a general acknowledgment of the inadequacy of the classical electrodynamics in describing the behavior of systems of atomic size. Whatever the alteration in the laws of motion of the electrons may be, it seems necessary to introduce in the laws in question a quantity foreign to the classical electrodynamics, *i.e.*, Planck's constant, or as it is often called, the elementary quantum of action. By the introduction of this quantity (h) the question of the stable configuration of the electrons in the atoms is essentially changed."

In other words, Bohr reasons that just as it has been found necessary to introduce a quantum theory of energy emission in order to acccount for the observed laws of distribution of energy in the spectrum of a black body, even so it is reasonable to assume that in the case of electrons vibrating in the atom, there exists some sort of discontinuity in the emission and absorption of energy. In this manner, Bohr is able to give a mechanical basis to the atom-model proposed by Rutherford.

The principal assumptions made by him are as follows:

(1) That the electrons revolve in circular orbits about the positive nucleus, with an angular momentum which is the same for all the electrons in the atom, and that during such revolutions the electrons do not emit any energy, although such an emission is to be expected from ordinary electro-dynamics. These states in which the electrons are merely revolving are known as "stationary" states of the system under consideration, and in these states the relation between the frequency of rotation, the average kinetic energy of the electron, and the radius of the orbit (r) can be calculated by the laws of ordinary dynamics.

(2) When, however, an electron passes from one stationary state to another, that is, from one orbit to another, there is an emission or absorption of energy, and the radiation emitted during such a transition is homogeneous and possesses a frequency (ν) which is determined by the relation

$$h\nu = A_1 - A_2$$

where h is Planck's constant, and A and A_2 are the energies of the system in the two stationary states.

From these assumptions, Bohr deduces a number of interesting results. He is able to account qualitatively at least for the Rydberg-Ritz law for the frequency of the lines in the ordinary spectrum of an element, and in the case of the hydrogen spectrum he derives the well-known Balmer formula for the series

$$\nu = K\,(1_2/T_2 - 1_2/T_{11})$$

where T_1 and T_2 are integers and K is the Rydberg constant. Bohr's calculated value of this constant is 3.284×10^{15}, while the observed value is 3.29×10^{15}. The agreement must be considered one of the most wonderful achievements of the theory.

Bohr also shows that on the basis of his assumption, the configuration of any system of electrons, *i.e.*, the frequency and linear dimensions of the rings, is completely determined when the nuclear charge and the number of electrons in the different rings are given. The physical and chemical properties thus depend upon the nuclear charge. In this conclusion, Bohr therefore agrees with Moseley and indeed he shows that Moseley's relation between the frequency as derived from measurements of the X-ray spectrum, and the nuclear charge follows directly from his assumptions.

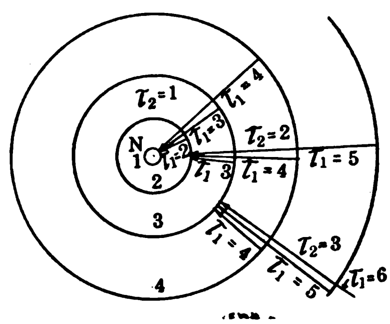

Fig. 2

The physical picture which Bohr would assign to the hydrogen atom may be illustrated by referring to Fig. 2.[4] "N represents the nucleus of the atom. The rings 1, 2, and 3 correspond to the orbits of the electron in the various steady states of motion. When an electron falls from one steady state to the next

3. *Phil. Mag. 26*, 1, 477, 857 (1913) also *30*, 394 (1915). An excellent review of the work of Bohr and Nicholson on the structure of the atom has been given by W. D. Harkins and E. D. Wilson, *J. Am. Chem. Soc. 37*, 1396 (1915). A summary of Bohr's theory has also been given by the writer in "Recent Views on Matter and Energy." *General Electric Review 17*, 1199 (Dec. 1914).

4. W. D. Harkins and E. D. Wilson, loc. cit.

one of small radius of vibration, one quantum of energy is liberated. In the fundamental spectral series, all the lines are formed by electrons falling from the second ring and beyond, all the way to the first ring. The first line in the series is due to an electron falling from the second to the first ring; the second line to an electron falling from the third to the first ring, and so on."

The different hydrogen series may be accounted for by assigning different values to T_1 and T_2 in the Balmer formula given above, and in the diagram Fig. 1, three such possible series are indicated. If $T_2 = 1$, and the values 2, 3 and 4 are assigned to T_1, we get a series which was not known at the time Bohr wrote his first papers, but which has since been found by Lymen in the Schumann region. "If $T_2 = 2$, and a series of values be assigned to T_1, the ordinary Balmer series for hydrogen results. For $T_2 = 3$, there results an infra-red series which was discovered by Paschen."

Bohr's most successful results have been obtained in dealing with atoms of hydrogen and helium. He has not extended his calculations much beyond the lithium atom, but he suggests the following possible scheme for the arrangement of the electrons in the lighter atoms. For each element the different numbers give the number of electrons in each ring, proceeding from the center outwards.

H	1				
He	2,	*Ne*	8, 2	*Ar*	8, 8, 2,
Li	2, 1	*Na*	8, 2, 1	*K*	8, 8, 2, 1
Bi	2, 2	*Mg*	8, 2, 2	*Ca*	8, 8, 2, 2
B	2, 3	*Al*	8, 2, 3	*Sc*	8, 8, 2, 3
C	2, 4	*Si*	8, 2, 4	*Ti*	8, 8, 4, 3
N	4, 3	*P*	8, 4, 3	*V*	8, 8, 4, 3
O	4, 2, 2	*S*	8, 4, 2, 2	*Cr*	8, 8, 4, 2, 2
F	4, 4, 1	*Cl*	8, 4, 4, 1	*Mn*	8, 8, 4, 4, 1

It will be observed that the elements are made to exhibit a recurring periodicity in the configuration of the electrons, which corresponds to the periodicity of chemical and physical properties. Also the number of electrons in the outermost ring corresponds in each case to the normal valency of the element.

While Bohr's assumptions have been questioned by a number of physicists and other views have been suggested notably by Nicholson and Thomson, yet it has been applied with a certain measure of success by Kossel to explain the periodic properties of the elements and the formation of chemical compounds and more recently Sommerfield, Born and Lande have attained marked success with it by showing how the elastic properties may be deduced from the Bohr model with only slight modifications in its assumptions.

However, Bohr's theory was certainly intended primarily to explain the origin of spectral series. As such it represents in the main the point of view of the physicist, and naturally fails in certain respects when tested from the chemist's point of view.

Theory of Atomic Structure by Lewis and Langmuir

In general, the chemists prefer to consider the valency electrons as fixed on the surface of the atom in definite positions, in contradiction with the assumptions made by Bohr and other physicists. There are innumerable observations in the field of organic chemistry, such as the existence of the asymmetric carbon atom and the phenomena of stereochemical hindrance, which lead to the conclusion that the valency electrons are stationary in the atom.

Moreover, some recent observations made by Dr. A. W. Hull of this Laboratory, on the structure of the iron atom, lend support to this theory.[5] He concludes from measurements of the intensities of the lines produced by allowing monochromatic X-rays to strike iron crystals, that "the electrons are displaced from the center of the iron atom along the diagonals of a cube in four groups of 2, 8, 8, 8, at distances 1/32, 1/16, 1/8, and 1/4 respectively of the distance to the nearest atom." That is, 24 electrons are arranged at the corners of three cubes, one fitting inside the other, with two electrons close to the center.

It is important to emphasize the fact that the choice by the physicists of an atom with rotating or vibrating electrons is due primarily to two causes: Firstly, in order to meet the requirements of dynamical stability, it is necessary to balance the attractive force between the electrons and the nucleus by some other force, and Bohr does this by assuming a centrifugal force due to the rotation of the electrons. This is quite similar to the case of the solar system where the gravitational force of attraction between the sun and the planets is balanced by the centrifugal force acting on the latter. Secondly, the assumption of rotating electrons offers a simple explanation of spectral series and as already shown above, Bohr has attained very marked success in this direction by such an assumption. On the other hand, if we assume the electrons to be stationary, it is necessary to assume that the electrostatic forces in the atom are balanced by some other forces than those due to rotation, and the most obvious assumption is that these are of electromagnetic nature.

A theory along these lines has been advanced by Parson.[6] He assumes that the electron itself is a rotating ring of negative electricity and is therefore a small permanent magnet; hence, the name *magneton*. The magneton at the surface of the different atoms exert magnetic and electrostatic forces on each other and thus lead to chemical combination. This theory necessitates, however, the existence of a uniformly charged sphere of positive electricity, as in the case of J. J. Thomson's model. Thus the arguments for

5. The method has been described by Hull in the *Physical Review* and by the author in "The Structure of the Atom," *General Electric Review*, 1917, pp. 496-7.

6. Smithsonian Inst. Report.

the atom with stationary electrons are weak from the physicist's standpoint, but very strong from the chemist's point of view. The latter has therefore frankly ignored this question of stability and is content to leave it for future solution.

The theory of an atomic structure with stationary electrons has been advanced tentatively by chemists at different times, but the first effort which attained any marked success is due to G. N. Lewis.[7] In order to account for the observed periodicity of the elements and the mode of formation of compounds, Lewis assumes that "the electrons arrange themselves in a series of concentric shells, the first shell containing two electrons, while all the other shells tend to hold eight. The outermost shell, however, may hold 2, 4, or 6, instead of 8. The eight electrons in a shell are supposed to be placed symmetrically at the corners of a cube or in pairs at the corners of a regular tetrahedron. When atoms combine they usually hold some of their outer electrons in common, two electrons being thus held for each chemical bond. These electrons may form parts of both atomic shells of eight electrons. By means of these postulates Lewis is able to give an extraordinarily satisfactory explanation of the periodic arrangement of the elements and to explain in detail most of their chemical properties. He confines his attention, however, exclusively to the inert gases, the alkali and the alkaline earth metals, the halogens, boron, aluminum, scandium, carbon, silicon, nitrogen, phosphorus, arsenic, antimony, bismuth, oxygen, sulfur, selenium, and tellurium, a total of 35 out of the 88 known elements."

Lewis' theory was published a couple of years ago, but did not attract the attention it deserves until very recently when Dr. Langmuir developed it still further and extended it to apply to all the elements.

"In attempting," he writes, "to determine the arrangement of electrons in atoms, we must be guided by the numbers of electrons which make up the atoms of the inert gases, in other words, by the atomic numbers of these elements, namely, helium 2, neon 10, argon 18, krypton 36, xenon 54, and niton 86."

Rydberg had pointed out that these numbers are obtained from the series

$$N = 2\,(+ 2^2 + 2^2 + 3^2 + 3^2 + 4^2 +)$$

The factor two suggests a two-fold symmetry and Langmuir therefore assumes:

Postulate 1. "That the electrons in the atoms of the inert gases are arranged about the nucleus in pairs symmetrically placed with respect to a plane passing through the nucleus which we may call the equatorial plane."

In order to account for the occurrence of the terms 1^2, 2^2, 3^2 and 4^2 in Rydberg's relation, it is necessary to assume:

Postulate 2. "That the electrons in the atoms are distributed through a series of concentric spherical shells. All the shells in a given atom are of equal thickness. If the mean of the inner and outer radii be considered to be the effective radius of the shell, then the radii of the different shells stand in the ratio 1: 2: 3: 4 and the effective surfaces of the shells are in the ratio 1: 4: 9: 16."

Postulate 3. "Each spherical shell is divided into a number of cellular spaces. The thickness of these cells measured in a radial direction is equal to the thickness of the shell and is therefore the same (Postulate 2) for all the cells in the atom. In any given atom the cells occupy equal areas in their respective shells. All the cells in an atom have therefore equal volumes. The first postulate, regarding symmetry applies also to the location of the cells. The first shell therefore contains two cells obtained by dividing the shell into two equal parts by the equatorial plane. The second shell having 4 times the surface (Postulate 2) contains 8 cells. The third shell thus contains 18 while the fourth contains 32 cells. Or if we consider only one hemisphere the numbers in the successive shells are 1, 4, 9 and 16."

Postulate 4. "Each of the two innermost cells can contain only one electron,[8] but each of the other cells is capable of holding two. There can be no electrons in the outside shell until all the inner shells contain their maximum numbers of electrons. In the outside shell two electrons can occupy a single shell only when all other cells contain at least one electron. We may assume that two electrons occupying the same cell are at different distances from the nucleus. Each shell, containing its full quota of electrons, thus consists of two 'layers.' We will find it convenient to refer to these layers of electrons by the symbols *I*, *IIa*, *IIb*, *IIIa*, *IIIb*, and *IVa* where the Roman numerals denote the shell containing the layer. Helium, neon, argon, krypton, or xenon, contains, respectively, the first 1, 2, 3, 4, or 5 of these layers, while niton contains all six."

These four postulates give us a definite conception of the electrons in the atoms of the inert gases. The arrangement of the cells in the different layers is seen more clearly from the following table, in which n represents the number of cells in the shell:

Layer	Radius	n	No. of cells: In axis	No. of cells: In zones
I	1	2	2	0
IIa	2	8	0	8
IIb	2	8	0	8
IIIa	3	18	2	16
IIIb	3	18	2	16
IVa	4	32	0	32

7. *J. Am. Chem. Soc.* 38, 762 (1916). This theory has also been discussed rather fully by the writer in the *General Electric Review*, 1917, pp. 403-406.

8. If, as Rydberg believes, there are two undiscovered elements of atomic weights less than that of hydrogen, then this exception in the case of the innermost cells may be avoided.

It will be observed that with this arrangement, the atom is symmetrical with respect to a polar axis passing through the nucleus and perpendicular to the equatorial plane, and since the cells all occupy equal areas in their respective shells, the atom as a whole presents four symmetrical planes passing through the polar axis and making 45 deg. angles with each other.

In attempting to arrive at the arrangement of the electrons in the outside layers of atoms other than the inert gases, Langmuir assumes three more postulates:

Postulate 5. "It is assumed that electrons contained in the same cell are nearly without effect on each other. But the electrons in the outside layer tend to line themselves up (in a radial direction) with those of the underlying shell because of a magnetic field probably always to be associated with electrons bound in atoms. (Parson's magneton theory). This attraction may be more or less counteracted by the electrostatic repulsion between the outside electrons and those in the underlying shell. The electrons in the outside layer also repel each other and thus tend to distribute themselves among the available cells so as to be as far apart as possible. The actual positions of equilibrium depend on a balance between these three sets of forces together with the attractive force exerted by the nucleus."

Postulate 6. "When the number of electrons in the outside layer is small, the magnetic attraction exerted by the electrons of the inner shells tends to predominate over the electrostatic repulsion, but when the atomic number and the number of electrons in the outside layer increase, the electrostatic forces gradually become the controlling factor. As a result when there are few electrons in the outer layer, these arrange themselves in the cells over those of the underlying shell, but where the outside layer begins to approach its full quota of electrons, the cells over the underlying electrons tend to remain empty."

Postulate 7. "The properties of the atoms are determined by the number and arrangement of electrons in the outside layer and the ease with which they are able to revert to more stable forms by giving up or taking up electrons, or by sharing their outside electrons with atoms with which they combine. The tendencies to revert to the forms represented by the atoms of the inert gases are the strongest, but there are a few other forms of high symmetry such as those corresponding to certain possible forms of nickel, palladium, erbium and platinum atoms towards which atoms have a weaker tendency to revert (by giving up electrons only)."

By means of these seven postulates it is possible to arrive at definite concepts with respect to the arrangement of the electrons in all the atoms.

The hydrogen atom contains a single electron and a nucleus of unit positive charge. The electron would on the average be situated on the polar axis of the atom. When we come to helium, the positive charge on the nucleus is two, and there are two electrons each situated at one end of the polar axis.

With lithium we begin the formation of a second shell and with each succeeding element up to neon, we add on one electron to those already present until with neon we have eight electrons situated symmetrically on the surface of a sphere and therefore resembling a cube in appearance. Thus, if we leave out of consideration the two electrons corresponding to helium, we can represent the elements from lithium to fluorine as cubes with one or more corners not filled by electrons, as shown in Fig. 3.

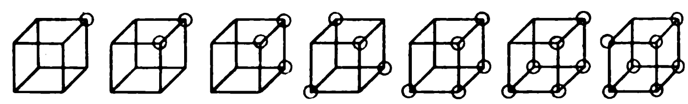

FIG. 3

Thus carbon would have two electrons in the inner shell (corresponding to the structure of helium) and four electrons on the outer ones, thus completing the six negative charges corresponding to the positive charge 6 on the nucleus. In order to account for tetrahedral symmetry of carbon, the four outer electrons are most probably situated on the four opposite corners of the cube, so that the lines joining them form a tetrahedron.

It is evident that this arrangement coupled with postulate 7 gives a very satisfactory representation of the chemical and physical properties of these elements. Thus lithium would tend to give up its single electron and revert to helium. This accounts for the high electropositive character of the element. On the other hand, fluorine may either take on an electron and thus resemble neon, or it may give up all its seven electrons to revert to helium. As the first alternative is much easier, we obtain a simple explanation of the electro-negative character of this element.

The mode of formation and properties of *LiF* are equally well accounted for. The lithium atom gives up its electron to the fluorine, leaving an atom which has a structure similar to helium with the addition of one more positive charge, while the fluorine atom in taking up the electron assumes a structure similar to that of neon, but with one less positive charge on the nucleus. Thus we form a substance which in the molten state is a good conductor of electricity; for the positively-charged helium atom (lithium ion, $\overset{+}{Li}$) will migrate towards the cathode, or negative terminal, while the fluorine atom with one extra negative charge (fluorine ion, $\overset{-}{F}$) will migrate towards the anode.

In a similar manner we can account for the formation of CH_4, NH_3, H_2O, and HF. In each case the atom of C, N, O, or F forms a system of eight by sharing the extra electrons with the hydrogen nucleus as

shown in Fig. 4 for NH_3. The white circles indicate the electrons belonging to N, while the black dots represent the electrons belonging to H. This view also accounts readily for the existence of ammonium ion as in NH_4F. (See Fig. 4) The hydrogen nucleus

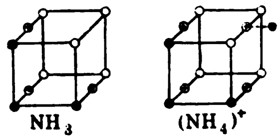

FIG. 4

belonging to the fourth H atom is shared by two of the electrons in the nitrogen atom, while the extra electron is held by relatively weak forces, just as the single electron in the case of lithium.

The elements in group *IIb* from neon to argon are quite similar to those in group *IIa*. The electrons in this layer tend to line themselves up with those of the underlying layer (see Postulate 5) and thus the elements are very similar to the corresponding elements of group *IIa*.

Beyond argon we begin the formation of a third shell. Until we reach iron the electrons arrange themselves symmetrically over the underlying electrons, so that the last mentioned atom has the structure assigned to it by Dr. Hull. That is, there are two electrons in the innermost shell and outside of this are three concentric cubes with eight electrons at the corners of each cube. In the case of cobalt and nickel the added electrons go into the polar axis, as they can no longer be arranged over underlying electrons, so that the main structure (that of the concentric cubes) remains quite similar to that of iron.

With the addition of another electron (to form the atom of Cu), the electrostatic forces of repulsion tend to overbalance the magnetic forces of attraction between electrons situated over each other and there is brought about a rearrangement of the electrons, so that the square containing the four electrons in each hemisphere tends to revolve 45 deg. about the polar axis. This arrangement, which Dr. Langmuir designates as the β-form of the Ni atom, has a higher degree of symmetry than the α-form previously considered, and thus represents the stable form towards which all the succeeding elements tend to revert (see Postulate 7). Consequently the atoms of the elements above nickel in giving up electrons tend to revert to this β-form of nickel. This is in accord with the fact that copper in the cuprous state has a valency of one, zinc has two, gallium three, etc., right up to selenium, six.

Arsenic, selenium and bromine, however, also tend to take up electrons (just as the corresponding elements N, O, and F in layer *IIa*) to form the very stable system constituting the atom of krypton.

When we come to deal with the electrons in the outer layer of shell *III* beyond krypton, we have an arrangement similar to that in layer *IIIa*, so that the elements beyond Pd tend to revert to a β-form of this element in which the electrons are situated immediately over those constituting the β-form of Ni.

With xenon the outer layer of the third shell is completed and the next series of elements is obtained by filling in successively each of the 32 cells which are present in the fourth shell. The first three or four elements beyond xenon tend to revert to the latter and thus show predominantly electro-positive character. These electrons and the successive additional ones tend to arrange themselves over the 18 of the underlying shell, "but by the time the 18 electrons have been added the electrostatic forces have begun to oppose the magnetic attraction degree. Therefore, when in tantalum an additional electron is added, the whole outside tends to rearrange itself so that the empty cells will come opposite the electrons of the underlying shell. The most symmetrical arrangement of this kind will occur when there are 18 empty cells opposite the 18 underlying electrons. The atomic number of niton in which the fourth shell is complete is 86— therefore an element having 18 empty spaces in the fourth will have an atomic number 68 corresponding to erbium. The structure of this β-form of erbium has the same kind of stability for large, nuclear charges that we found in the cases of B-nickel and B-palladium. We may therefore expect that the atoms beyond lutecium will show a marked tendency to revert to β-erbium. Thus tantalum with an atomic number 73 tends to lose five electrons and tungsten to lose six. The properties of tantalum and tungsten thus resemble those of columbium and molybdenum but because of the complexity of the atom to which they revert, and in general because of the large numbers of electrons in their outside shell, their secondary valence forces are more highly developed."

A remarkable feature of this point of view is the manner in which it accounts for the existence of the so-called "rare earth" elements beginning with cerium and ending with lutecium (*Lu*). These are shown enclosed in the dark lines in Fig. 1. They are all chemically similar in properties and show no characteristic valency, so that it has been apparently impossible to group them with any other elements.

The present theory, however, would lead to the conclusion that after the third or fourth electron is added in the fourth shell, the succeeding elements would exhibit just this kind of resemblance and lack of definite valency. Furthermore, this family resemblance ought to cease with the addition of the eighteenth electron, which as a matter of fact corresponds to lutecium, and this marks definitely the last of the rare earths.

From the point of view of this theory, the rare earth group of elements is just a repetition on a larger scale of a similar interesting fact observed in the case

of the elements *Ti, V, Cr, Mn, Fe, Co, Ni* and *Cu* whose electrons are situated in layer *IIIa*. All these elements show more or less similar chemical properties and lack of characteristic valency.

"The β-form of the erbium atom contains 18 empty cells arranged over the 18 cells of the third shell. When electrons are added as we pass to elements of large atomic number, the first eight of them naturally tend to arrange themselves at the corners of a cube, because of the magnetic attraction of the eight electrons in the second shell. The next two electrons for reasons of symmetry then arrange themselves in the polar axis. We thus have the three eight group elements osmium, iridium and platinum.

"The next elements gold, mercury, etc., are distinctly diamagnetic. The same sharp break occurs here as we found between nickel and copper, palladium and silver, lutecium and tantalum, although its magnitude is much less. We may therefore assume that beyond platinum the electrons tend to rearrange themselves in a β-form in which the ten electrons that have been added since erbium endeavor to get farther away from those of the underlying electrons. The eight empty cells tend to take symmetrical positions in the atom probably at corners of a cube, and the cells containing electrons, space themselves as best they can. The fact that an arrangement of this kind does not have nearly the symmetry which we found for the β-form of the nickel atom is probably the explanation of the fact that the tendency of the succeeding elements to revert to this β-form of platinum is much less marked than we observed in the cases of reversion to nickel, palladium and erbium. Thus we find that gold and mercury have variable valence differing in this respect from silver and cadmium. Thallium forms univalent and tervalent ions whereas indium forms only tervalent. Lead only exceptionally is quadrivalent, while this seems to be normal condition of tin compounds. Thus stannous salts are strong reducing agents, but divalent lead salts are not. Bismuth is normally tervalent and forms only a few very unstable compounds in which it is quinquivalent. Antimony on the other hand has about equal tendencies to be tervalent or quinquivalent.

"With niton the first layer of electrons in the fourth shell is completed. As we add more electrons we should expect to go through the same cycle as that of the rare earth period. The properties of the first two or three elements are determined primarily by the ease with which they give up electrons. Thus radium very closely resembles barium, differing from it in chemical properties only by its slightly greater secondary valence which manifests itself here by slightly decreased solubility of its salts.

"Thorium resembles cerium and zirconium, the elements of similar constitution."

The last shell of electrons beginning with niton (atomic number 86) is incomplete. This must be due to increasing instability of the nucleus, as is shown by the fact that the elements beyond thallium exhibit the phenomena of nuclear disintegration.

Langmuir shows that by means of this theory of atomic structure it is possible to explain not only the periodic properties of all the elements, but also the magnetic properties, and a large number of the so-called physical properties such as boiling points, freezing points, electrical conductivity, etc.

Mention has already been made of the manner in which the theory can be applied to explain the mode of formation and properties of some of the simpler chemical compounds. As well known, the ordinary theory of valence which has been found so useful in accounting for the formation of just these kinds of simple compounds, is found to be inapplicable in a large number of cases, notably those of inorganic compounds. Langmuir's theory, however, leads to a simple theory of valence which applies equally well to all kinds of compounds. This theory, which may be designated as the theory of octets, is based upon the following simple equation:

$$e = 8n - 2p,$$

where e is the total number of electrons available in the outer shells of all the atoms in a molecule; n is the number of octets forming all outside shells, and p is the number of pairs of electrons held in common by the octets.

On this basis, the single bond of the ordinay theory is replaced by a pair of electrons. Thus, in the case of CO_2, if we place $n = 3$, $e = 4 + 2 \times 6$, and solve for p, we find that four pairs of electrons must be held in common, and the molecule must therefore be represented by some such structure as that shown in Fig. 5.

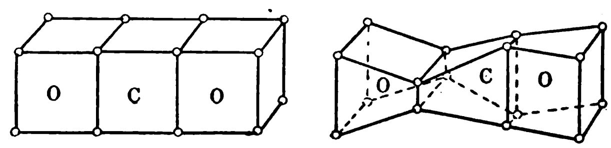

FIG. 5

According to the classical theory we would assign four bonds to the carbon atom so as to satisfy the two bonds belonging to each of the oxygen atoms. Similarly two atoms of fluorine would combine, according to the octet theory, to form a molecule, F_2, by sharing one pair of electrons. In his paper Langmuir shows how the theory can be applied to explain the mode of formation of different compounds of *N, P, S*, and other elements for which the ordinary theory is entirely inadequate.

An interesting theory is suggested of the structure of the molecules of N_2, CO, HCN, and NO. In these four cases it is assumed that the kernels of both atoms in the molecule are contained within a *single octet*. Thus of the 14 electrons available in two atoms of nitrogen or in the atoms of carbon and oxygen, eight

form an octet and contain inside this octet the other six, together with the corresponding kernels. "This accounts for the practically identical physical properties of nitrogen and carbon monoxide and for the abnormal inertness of molecular nitrogen."

Conclusion

There is no doubt that Langmuir's theory of atomic structure has proved extremely successful from the chemist's point of view. That its conclusions are apparently at variance with Bohr's theory, may prove in the near future to be not quite as much the case as it looks at present. It must be observed that all of Langmuir's conclusions would be just as valid if we assume that the electrons are not actually stationary, but rotating or vibrating about mean positions which are located at the points in the atom corresponding to the centers of Langmuir's electronic cells. As stated by Langmuir, "Bohr's stationary states have a rather close resemblance to the cellular structure postulated in the present theory. There are also striking points of similarity with J. J. Thomson's theory of the structure of atoms, in which he assumes that the attractive forces are limited to certain tubes of force. It is probable, however, that the cellular structure is not so much a property of space as of the electron. It seems that the electron must be regarded as a complex structure which undergoes a series of discontinuous changes while it is being bound by the kernel or nucleus of an atom. There seems to be strong evidence that an electron can exert magnetic attractions on other electrons in the atom even when not revolving about the nucleus of the atom."

It is quite probable that a complete theory of atomic structure will not only reconcile the chemical properties of the atom with the fundamental truth enunciated in Bohr's derivation of the Rydberg constant, but also will, at the same time, give us a physical concept of the quantum theory which we lack at present.

ELECTRON TUBE GENERATORS

The determination of the output characteristics of electron tube generators is the subject of Scientific Paper No. 355 of the Bureau of Standards. The paper points out that owing to saturation and rectification effects in three-electrode vacuum tubes, the currents which they deliver to any type of output circuit, when used as a generator, are heavily loaded with harmonics. Experimental results indicate that the frequency of the oscillating currents generated is the natural frequency of the output circuit. Hence this circuit behaves as a filter in series with the tube and the d-c. power system, and the useful output current is approximately sinusoidal, whatever the distortion of the tube currents, depending in amplitude solely upon the fundamental constituents of the tube currents.

General expressions are derived for the power and current output in terms of static characteristics of the generating tube, and are corroborated by experimental results obtained with a particular tube.

Copies of the paper may be obtained by addressing a request to the Bureau of Standards, Washington, D.C.

APPRECIATION

The following excerpts are taken from some of the many letters of appreciation which have recently been received by the Secretary and the Editor in regard to the new Journal of the A. I. E. E.:

I just want to add a personal word and a word to the officers expressing my pleasure at the publication of the new Journal of American Institute of Electrical Engineers. It seems to me to be a remarkably creditable publication, and I hope that you will not have too great difficulty in the future living up to the standard which has been set.

F. B. Jewett, New York.

The first copy of your new Journal arrived on my desk this morning and I wish to offer my hearty congratulations to you on the splendid publication which you have produced. It is a credit to yourself and to the Institute and I trust that the change you have inaugurated will be of great benefit to the Institute.

Fraser S. Keith, Montreal, Can.

I take this occasion to congratulate you upon the excellent appearance of your January Journal, and upon the significance of the new policy which its appearance represents.

W. F. M. Goss, New York.

I want to take this opportunity to congratulate you upon the Journal, of which the Institute has just issued its first copy. It is a splendid piece of work, and reflects credit on all who had anything to do with it.

Fred'k C. Bates, New York.

I wish to express my appreciation of the quality of the material in the first issue of the Journal of the American Institute of Electrical Engineers. If this excellence is maintained, I predict that the Journal will become the most valued of any publication in the electrical field. The articles are all practical and are written within the comprehension of the average reader.

D. E. Carpenter, Scranton, Pa.

The new form of the Journal pleases me very much, and I wish to express to you my appreciation of the new publication. Surely it has made a splendid beginning, and I look forward to enjoying the coming issues immensely.

Good luck to the Journal, and more power to your elbow!

C. H. Sanborn, Allston, Mass.

Permit me to congratulate you and your editor, Mr. Metcalfe, upon the very pleasing appearance of the Journal of the American Institute of Electrical Engineers in its new form.

Alfred D. Flynn, New York.

I want to congratulate you on the splendid appearance of the January issue of your Journal. It is certainly a credit to any association. I was particularly interested in the lower half of page 5 of the advertising section.

Rodman Gilder, New York.

Essential Statistics for General Comparison of Steam Power Plant Performance

BY W. S. GORSUCH

Engineer, Economics, Interborough Rapid Transit Co., New York, N. Y.

This paper briefly outlines a method for preparing statistical reports relating to power generation in steam power plants, whereby fairly close comparisons can be made of the efficiencies between different plants, without going into a detailed study of the thermal characteristics of the plants, or the intricate subject of power costs.

The essential items of steam power plant performance that should be recorded and a uniform method of expressing them, are given in tabular form, followed by an illustration demonstrating the advantage of the proposed method.

THE principal difficulty with operating statistics of steam power plants as published today by various State and Governmental bodies is that they are wholly inadequate for the purpose of determining the efficiency of a plant or making general comparisons between different plants. In practically every case the bare figure of coal consumption per kilowatt-hour is given without any reference whatever to the quality of coal and without a clear understanding as to the character of the load on the station. When load factors are given, the figures are often misleading because they are computed upon different bases. No uniformity exists in reporting the output of the power plant, the gross output being used in some cases and the net output in others. Because of these facts the reports as at present published are limited in their use, principally serving to show the total amount of power generated and the total quantity of coal consumed.

The object of this paper is to point out the essential items of steam power plant performance which should be recorded in statistical reports, and to suggest a uniform method of expressing them for the purpose of making a general comparison between different plants, without going into an analysis of the thermal characteristics or cost of generation.

It must be conceded that the proper criterion for comparing power plants is the commercial efficiency, that is, the total cost per kilowatt-hour sent out from the a-c. power station bus, which is the ultimate test of design and operation. To make such a comparison, a uniform system of accounting would have to be adopted, and suitable correction factors would have to be established whereby the operating results and conditions can be reduced to a more or less common basis, all of which is beyond the scope of general statistical reports. For this reason, the discussion of costs in this paper will be limited to that of coal which is the largest single item in the cost of generation.

What is said here refers particularly to steam power plants using coal as fuel and in which all the output is in the form of electrical energy, but the principles relate in their broad application to steam power plants using fuel other than coal and where both steam and electrical energy are supplied.

For the purpose of obtaining a better knowledge of what a plant is doing and for judging the relative merits of different plants, it is recommended that the following items be recorded in statistical reports relating to power generation in steam power plants, and that they be expressed in a uniform way as indicated. These items reflect the influence of station design and arrangement of apparatus, method of operation and management, load, quality and kind of fuel used, and at the same time indicate the character of the load imposed upon the station. For convenience the items are divided into two groups, coal characteristics and load characteristics.

I. *Coal Characteristics of the Plant*
- (1) Average B.t.u. supplied to plant per kw-hr. net output.
- (2) Thermal efficiency of plant in per cent.
- (3) Average B.t.u. per dollar, coal as received (moist basis).
- (4) Coal factor or pounds of coal per kw-hr. net output (moist basis).
- (5) Average B.t.u. per pound of coal as received (moist basis).
- (6) Cost of coal per ton (2240 pound) delivered alongside the plant.
- (7) Kind and character of coal.
- (8) Cost of coal in cents per kw-hr. net output.

II. *Load Characteristics of the Plant*
- (9) Average daily load factor of load
- (10) Maximum load for the year.
- (11) Yearly load factor of load.

  (Items 9–11:) Interval of maximum load 15 minutes or 1 hour depending upon character of load.
- (12) Kilowatt-hours net output for the year—(kilowatt-hours sent out from the a-c. bus).
- (13) Installed rated capacity, that is, the aggregate maximum continuous rating of the generators in kilowatts.
- (14) Average kilowatt-hours net output per kilowatt installed rated capacity.

Items 1, 2, 3, 8, 11 and 14 can readily be computed from items 4, 5, 6, 10, 12 and 13.

Coal Characteristics. The fundamental basis of determining and comparing steam power plant efficiencies as to coal consumption should be the average B.t.u. supplied per kilowatt-hour net output at the power station bus. This will give a basis for discussing and comparing plant efficiencies upon which there can be no misunderstanding. With this factor and a knowledge of the character of load, we have a very good criterion by which to judge the merits of a plant both as to design and operation. The average B.t.u.

To be presented at the Midwinter Convention of the A. I. E. E., New York, February 18, 1920.

supplied to the plant per kilowatt-hour net output for the year is determined by dividing the kilowatt-hour net output for the year into the product of the total pounds of coal used during the year by the average B.t.u. per pound of coal as received, (moist basis). This measure of efficiency can be expressed in thermal efficiency or what is generally termed over-all plant efficiency, by dividing it into 3415.

Before a very close comparison can be made between two plants each of which uses a different grade of coal, the coal characteristics of both plants will have to be placed on the basis of coal having the same quality. This involves the effect of quality of coal on the boiler capacity and efficiency which must be taken into account if the object sought is to make an analysis of the thermal characteristics of the plants. However, since the purpose of this paper is to deal with general comparisons which can be made from statistical records without going into a detailed study of the plants, it is proposed to make fairly close comparisons which correct for the difference in the B.t.u. value of the coal itself, but which neglect the effect on the boiler capacity and efficiency. Notwithstanding this inaccuracy which will be relatively small, even with a large difference in the quality of coal, the comparisons as outlined are much more useful than any that can possibly be made from the statistical information published today.

Two plants can be directly compared as outlined above on the basis of the average B.t.u. supplied per kilowatt-hour net output, because both the coal factor and quality of coal are taken into account. A comparison however, cannot be made between the coal factors as given without first correcting for the difference in the B.t.u. value of the coal used. This can be done by multiplying the coal factor of either plant by the ratio of the B.t.u. value of the coal used by that plant, to the B.t.u. value of the coal used by the other plant, thus placing the coal factors on the same basis in so far as the B.t.u. value of the coal itself is concerned.

Because of the lack of laboratory facilities it may not be possible for some small plants to determine the average B.t.u. value of all the coal consumed during the year. In such cases the results of periodic tests should be recorded with an explanatory foot-note, as they will serve to give a general idea of the conditions under which the plant is being operated. There is nothing that upsets the boiler room force so much as changing the grade of coal without notice, since every change necessitates a readjustment of methods of firing. With a knowledge of just what kind of coal is being supplied, the cause of the change in efficiency can more readily be traced.

Generally speaking, the highest thermal efficiency is obtained when burning the highest quality of coal. On the other hand, a low grade of coal purchased at a low price may result in a better commercial efficiency. The B.t.u. per kilowatt-hour net output together with the B.t.u. per dollar will, therefore, give an index of the commercial efficiency of the plant, since coal is by far the largest item in the cost of power production.

Where mixed fuel is used, the relative amount of anthracite and bituminous coal should be recorded, together with the average B.t.u. value of each.

Load Characteristics. The character of load carried has a marked influence on plant efficiency, a fluctuating load and a load with sharp peaks and low load factor require more coal than an equally steady load or a load with a high load factor. In comparing plant performance therefore, it is essential to know the load conditions. These are best indicated by the ratio of the average load to the maximum load for the same period, which is known as the load factor of load and is usually expressed in percentage. Industrial and railway loads are less affected by seasons and daily weather conditions than lighting loads. For this reason it is recommended that the interval for the maximum load be fifteen (15) minutes for stations supplying an appreciable lighting load, and one (1) hour for all other stations.

Much confusion is caused throughout the electrical industry, due to the fact that a uniform method has not been used in determining the load factor. For the purpose of comparing the load conditions of various generating stations, the daily load factor seems to be most suited, and it should be the ratio of average net output during 24 hours to the net maximum load, multiplied by 100 to express in percentage. The load factor should be computed on the basis of 24 hours for the reason that it represents the relation between the actual and possible hours use of the maximum load. In comparing power station statistics which are usually on a yearly basis, the average daily load factor should be used because it is more representative of the operating conditions in the plant itself than a load factor based on the maximum of the month or year.

The fundamental basis of determining and comparing those items of power plant performance that are expressed in terms of unit output of the plant, should be the kilowatt-hour net output. This will eliminate any difference in power consumption of auxiliaries or power used for other purposes in the plant. The result will be that all the factors will be on the basis of the character of load imposed upon the plant.

The plant factor which is the ratio of the average hourly load for the year to the rated capacity of the plant is a measure of the utilization of the installed capacity. This is obtained by dividing 8760 into Item 14.

For the purpose of illustrating the advantage of the proposed over the present method for preparing statistical reports relating to power generation in steam power plants, the following comparison is made between a few of the items of two plants, A and B, which have similar load characteristics, but which use coal differing in quality and price.

	Plant A	Plant B
I. *Coal Characteristics of the Plant*		
1. Average B.t.u. supplied to plant per kw-hr. net output	22,400	25,600
2. Thermal efficiency of plant in per cent	15.24	13.34
3. Average B.t.u. per dollar, coal as received (moist basis)	5,226,666	5,734,400
4. Coal factor, or pounds of coal per kw-hr. net output (moist basis)	1.60	2.00
5. Average B.t.u. per pound coal, as received (moist basis)	14,000	12,800
6. Cost of coal per ton (2240 lb.) delivered alongside plant	6.00	5.00
7. Kind of coal	Bituminous	Bituminous
8. Cost of coal in cents per kw-hr. net output	0.428	0.446
II. *Load Characteristics of the Plant*		
9. Average daily load factor of load. } Interval of maximum load one hour	50	54
10. Maximum load for the year. } Interval of maximum load one hour	90,000	80,000
11. Yearly load factor of load. } Interval of maximum load one hour	40	38
12. Kw-hr. net output for the year.—(kw-hr. sent out from the a-c. bus)	315,460,000	217,248,000
13. Installed rated capacity, that is, the aggregate maximum continuous rating of the generators in kw	125,000	100,000
14. Average kw-hr. net output per kw. installed rated capacity	2,525	2,173

A comparison of Items 1 and 2 shows that on the basis of plant *A*, plant *B* has a 12.5 per cent lower plant efficiency and requires 14 per cent more B.t.u. per kilowatt-hour net output at the station bus. If the effect on boiler capacity and efficiency due to quality of coal are neglected, the lower efficiency for plant *B* can be attributed principally to a difference either in station design or method of operation or both since the load characteristics are practically the same.

The equivalent coal factor of plant *B* based on coal having 14,000 B.t.u. per pound, is 1.83 pound or 0.23 pounds more per kw-hr. net output than that required for plant *A*. This means that for the same output and with coal having the same B.t.u. value, plant *B* consumes approximately 14 per cent more coal than plant *A*.

With the present method of recording power plant statistics, Item 4 showing the coal factors would be given, but Items 1, 2, 3, and 5 would not. In this case it would be impossible to tell whether or not any part of the difference in the coal factors was due to the quality of coal. If the relative merits of the two plants were judged from the coal factors alone, the comparison would be misleading for the reason that while the coal factor for plant "*B*" is 25 per cent higher than that for plant "*A*", the B.t.u. supplied per kw-hr. net output is only 14 per cent higher. This very clearly brings out the fact that a general comparison cannot be made between the coal factors of two plants without a knowledge of the relative B.t.u. value of the coals used.

Other interesting comparisons can be made from the above tabulations, one of which is the cost of coal per unit of output. The figures given in item 8 show that the cost of coal per kw-hr. net output for plant "*B*" is approximately 4.2 per cent higher than that for plant "*A*".

The above discussion demonstrates the need of a uniform standard method of recording the fundamental factors of steam power station performance in statistical reports, and this paper is presented with the hope that some action will be taken to adopt such a method.

RECENT PROGRESS OF ELECTRIC PROPULSION IN U. S. NAVY

The Navy has recently announced the award of a number of new contracts for electrical machinery to propel the new Battle Cruisers and Battle Ships.

The Battle Cruisers are to have a displacement of about 44,000 tons, a maximum speed of 34 knots and fractional speeds at which the economy will be very good. To achieve this high speed will require about 180,000 horse power per ship. This power will be derived from four large steam turbines, each driving a 40,000. kv-a. three-phase, 5000-volt generator at 1835 rev. per min. There will be four propeller shafts on each of which will be mounted two three-phase induction motors of 23,000 h.p., each having 22 poles and running at 331 rev. per min. These motors are designed to operate also with 44 poles giving 6800 h.p. at 170 rev. per min., the condition for half speed.

The new Battle Ships are larger than the New Mexico, being designed for a displacment of 43,000 tons and require 60,000 h.p. to drive them at their contract speed of 23 knots. The power for the battle ships will be derived from two turbine-driven electric generators rated as 22,000 kv-a., two-phase, 5000 volts, 1800 rev. per min. There will be one induction motor on each of the four propeller shafts, each motor rated as 15,000 h.p. at 225 rev. per min. with 16 poles. For fractional speed running the motors will be arranged with 24 poles giving 3600 h.p. at 150 rev. per min.

The contracts for the power plants for these ships have been awarded to the General Electric and the Westinghouse companies respectively.

The Bureau of Census states that according to a report about to be issued showing results of census of telephones covering the year 1919, there are 53,234 separate telephone systems and lines. These lines and systems operated 28,827,188 miles of wire in United States, and connected 11,716,520 telephones and 21,175 public exchanges. Messages sent over these wires aggregated total of nearly 22,000,000,000.

Inherent Regulation of Continuous Current Circuits

BY A. L. ELLIS

Thomson Laboratory, General Electric Company, Lynn, Mass.

AND

B. W. ST. CLAIR

Standardizing Laboratory, General Electric Co., Lynn, Mass.

This paper discusses the voltage changes, inherent in d-c. circuits, upon change of load. These variations are independent of i r drops or speed of prime movers. A simple means of mitigating their effect is given.

Introduction

IN developing a device to measure time to one millionth of a second we were at one time confronted with the question, how is the voltage of a "flat" compounded generator affected by an increase or decrease of load? We were not interested in what happened as indicated by a voltmeter, (as the generator was carefully compounded for the range of load under consideration), but what happened at the instant the load was changed. We were surprised at the extent of the voltage drop, indicated by the oscillograph, when the load was increased. The very interesting oscillograms and data resulting from further investigation of this drop form the basis of this paper.

The principles governing this drop are set forth in elementary text books on engineering, and while simple in this form their application to a network of conductors supplied with current by a generator is difficult to follow, and when mathematically stated lead to very complex equations that can be comprehended only by a painstaking study of the problem.

The result is that the busy engineer with insufficient time to concentrate upon this subject frequently encounters, in practise, manifestations of this drop without realizing the cause or recognizing the principle.

We find very little written on the subject; a suggestion of it here and there in articles referring to transients, and with the exception of reference made to it in Lamme's paper[1] on commutation, no comprehensive statement of the case has come to our notice.

The simple explanation of this dip in voltage given in Lamme's paper follows verbatum: "Assume, for instance, a 100-volt generator supplying a load of 100 amperes—that is, with one ohm resistance in circuit. The drop across the resistance is, of course, 100 volts. Now, assume that a resistance of one ohm is thrown in parallel across the circuit. The resultant resistance in circuit is then one-half ohm. However, at the *first instant* of closing the circuit through the second resistance, the total current in the circuit is only 100 amperes, and therefore the line voltage at the first instant momentarily must drop to 50 volts. However, the e. m. f. generated in the machine is 100 volts, and the discrepancy of 50 volts between the generated and the line volts results in a very rapid rise in the generator current to 200 amperes. If the current rise could be instantaneous, the voltage dip would be represented diagrammatically by a line only; that is, no time element would be involved. However, *the current cannot rise instantaneously in any machine*, due to its self-induction, and therefore, the voltage dip is not of zero duration, but has a more or less time interval. The current rises according to an exponential law, which could be calculated for any given machine if all the necessary constants were known. However, such a great number of conditions enter into this that it is usually impracticable to predetermine the rate of current rise in designing a machine; and it would not change the fundamental conditions if the rate could be predetermined, as will be shown later."

Lamme points out that, "If a given load is thrown on a machine, the dips will be relatively less the higher the load the machine is carrying. Also, if the *same percentage* of load is thrown on each time, then the dips should be practically the same, regardless of the load the machine is already carrying." He also gives a table of test results to substantiate this taken from oscillograph curves which were considered too faint to be reproduced in the paper.

In our investigation of the "dip" we were able to get very good oscillograms though the phenomenon is a difficult one for the oscillograph to record. It is the purpose of this paper to extend the evidence by oscillograph records and plots drawn up from a mathematical consideration of a range of ideal circuits, which give at a glance a better understanding of the relative importance of various conditions than would be disclosed in pondering over a word picture.

Load Increments

Several types of generators were examined and the "dip" found in all in accordance with the theory within the limitations of the oscillograph.

The following oscillograms were obtained from the same generator under various conditions of load and may be considered to represent fairly the performance of any continuous-current generator, making due allowance for generator constants.

The performance of any continuous-current generator in this regard can be more easily understood by considering what happens when

A non-inductive load is added to a generator carrying no load........................(Case one);

An inductive load is added to a generator carrying no load........................(Case two);

To be presented at the 8th Midwinter Convention of the A. I. E. E., New York, February 19, 1920.

1. B. G. Lamme, "Physical Limitations in D-C. Commutating Machinery." TRANS. A. I. E. E. 1915, Part II.

A non-inductive load is added to a generator carrying a non-inductive load.............(Case three);
An inductive load is added to a generator carrying a non-inductive load..............(Case four);
A non-inductive load is added to a generator carrying an inductive load..................(Case five);
An inductive load is added to a generator carrying an inductive load..................(Case six).

CASE ONE

If an ideal non-inductive resistance is thrown on the circuit of a separately excited generator carrying no load, there will be an instant demand for current of value $\frac{E}{r_1}$ where E is the voltage at the terminals to which load is applied and r_1 is the resistance of the applied load.

Owing to the inductance of armature and leads, current cannot be supplied instantly, and as no current was flowing before load was applied and did flow afterward, obviously it must have increased from zero value. As $E = IR$ the voltage must drop to zero at the instant the load is applied, and increase along a simple exponential curve depending only upon the time constant of the circuit, to the value equal to the generated voltage minus the internal IR drop.

The drop to zero is therefore, fundamental and is independent of the type of the generator, its size, its generated voltage, or the value of the applied load. These variables influence only the time of recovery to normal voltage and the form of the recovery curve.

Considering the inductance of the circuit to be confined to the armature: The instant demand for current gives rise to an e. m. f. of self-induction which opposes any increase of current (at that instant zero) and with respect to the generated voltage is therefore a counter e. m. f. The value of this counter e. m. f. with respect to the value of the generated voltage at any instant during the transient, is just sufficient to allow current to flow into the circuit at a rate such that the e. m. f. of self-induction ($L \frac{di}{dt}$) at any instant added to the IR drop at that instant equals the generated voltage. Therefore, at the instant when load was applied and the current was zero the counter e.m.f. of self-induction just equaled the generated voltage in value, consequently the voltage of the circuit reduces to zero.

If, as in all practical cases, part of the inductance is in the leads of the external circuit, the voltage at the generator terminals should drop instantaneously to a value approaching zero as the inductance of the external circuit approaches zero.

Capacity effects greatly complicate matters and their consideration precludes a simple presentation of the phenomena. This is particularly so in the case of underground cable distribution where we find distributed capacity and inductance to a considerable extent. However, in the case of isolated plants, overhead distribution, and branches of underground systems shut off, as it were, by the inductance of protection devices, instruments, meters, etc., the available capacity is, in general, so small as compared to the instant demand for energy that capacity effects have been neglected. Those who wish to consider capacity effects in connection with this phenomenon can refer to such standard works as "Transient Phenomena" by C. P. Steinmetz, and "Propagation of Electric Waves Along Telegraph Conductors" by J. A. Fleming.

The following conclusions and equations assume lumped constants that remain constant during the time necessary for the readjustments to take place, and are applicable also to battery circuits where there is a series inductance that would correspond to the inductance of the generator armature, as for instance, the series coils of a circuit breaker or watt-hour meter.

As previously pointed out, applying a non-inductive load to an unloaded generator results, at the generator terminals, in an instantaneous drop of voltage to zero. From this point the voltage returns to normal value according to an exponential curve.

$$e = E\,(1 - \epsilon^{-\alpha_1 t}) \qquad (1)$$

where

e is voltage at any instant
E = normal voltage
t = time since application of load.

$$\alpha_1 = \frac{r}{L_a}$$

where

r = complete resistance of circuit.
L_a = inductance of armature.

Equation **1** can be developed from

$$e = i r_1 \qquad (2)$$

where i is instantaneous value of current
r_1 = resistance of applied load.
and

$$i = I\,(1 - \epsilon^{-\alpha_1 t}) \qquad (3)$$

where $$I = \frac{E}{r_1}$$

At $t = 0$, that is at the instant of closing the switch $\epsilon^{-\alpha t}$ reduces to 1, and equation **3** becomes

$$i_{(t=o)} = 0 \qquad (4)$$

which substituted in (**2**) reduces (**2**) to

$$e_{(t=o)} = 0$$

From the foregoing it will be seen that the voltage drop is independent of the value of the resistance applied, also that the velocity of return to normal is a function of the resistance, and an inverse function of the inductance.

The natural question as to the whereabouts of the voltage generated by the rotating armature of the

machine, which is dependent only upon the speed of rotation and the strength of field, can be answered by a study of the reactions of the armature itself, the instant of closing the circuit.

Because the armature is inductive it resists any attempt to change the value of current flowing in it by a counter e. m. f. $= e_c$

$$e_c = L_a \frac{di}{dt} \tag{5}$$

which by differentiating (3) with respect to t, and substituting in (5) becomes

$$e_c = rI\,\epsilon^{-\alpha_1 t} \tag{6}$$

$$= E\,\epsilon^{-\alpha_1 t} \tag{7}$$

which at $t = o$ becomes

$$e_{c\,t=o} = E$$

From **7, 3,** and **2** it is seen that the sum of the external ir_1 voltage and the armature reactance voltage neglecting armature resistance, is always equal to the generated voltage, that is

$$ir_1 + L_a \frac{di}{dt} = E$$

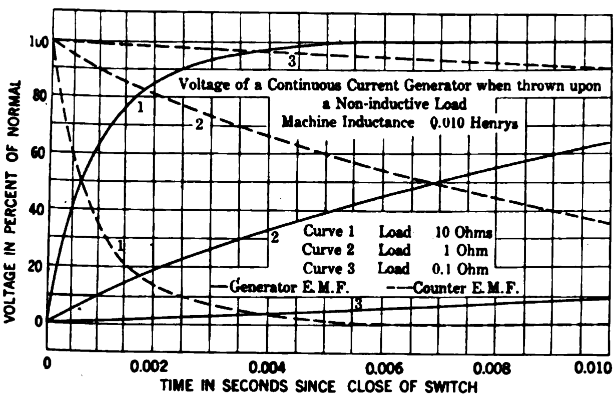

Fig. 1

Fig. 1 is a plot from calculated values and illustrates how a change in the value of the applied non-inductive load affects the shape of the voltage recovery curve and the time of recovery. The solid lines represent current increase as well as generator e. m. f. The broken lines represent the decrease in counter e. m. f. as the current approaches its steady value. The sum of the generator voltage and the counter e. m. f. at any instant during the transient equals 100 per cent of the generator voltage when the transient terminates.

Some oscillograms from actual tests are shown in Fig. 2. None of these show the voltage drop completely to zero, as should be expected, for a simple calculation is sufficient to show that in every case, the rate of rise of voltage was such that, assuming a natural period of 4000 cycles per second for the oscillograph vibrator, the voltage would be sufficiently great to give measurable deflections before the vibrator could return to zero. The table of test results given in Lamme's paper, taken from oscillograph curves, does not indicate sufficient drop in cases where the added load was a large part of the combined load, particularly where a load of 417 amperes was added to a 1200-volt generator carrying no load. The volt "dip" from 1200 to 500, there recorded, we believe due to the limitations

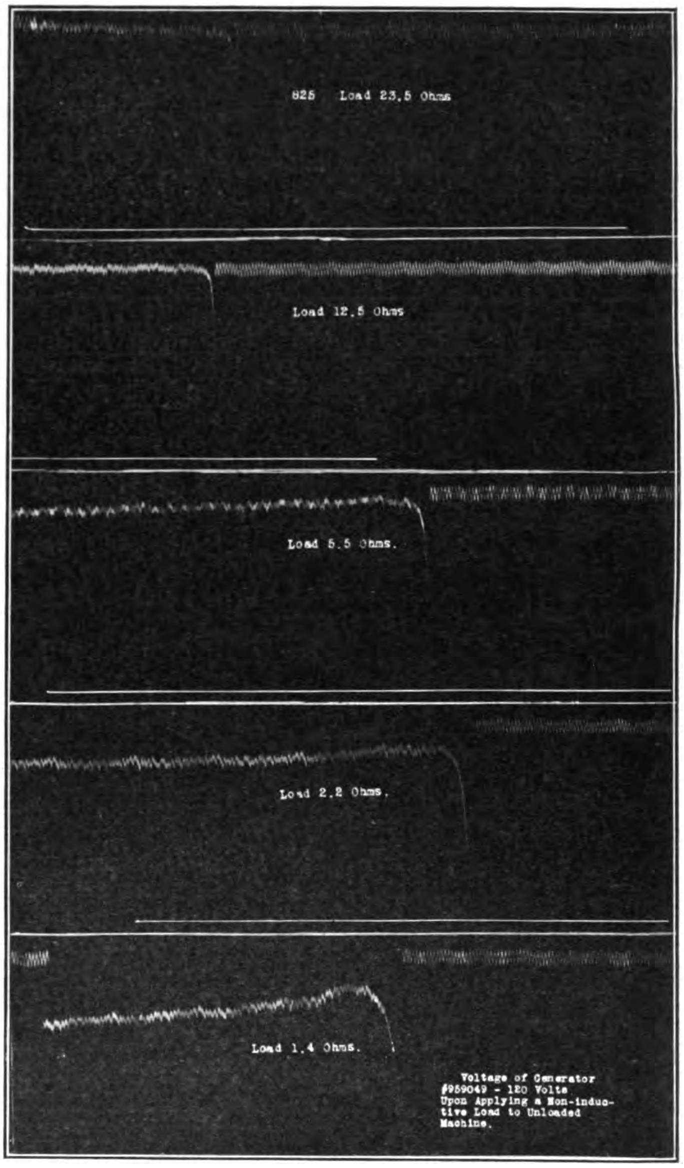

Fig. 2

of the oscillograph (mentioned by Lamme), should have been substantially to zero volts.

The oscillograms show clearly the variation in the rate of recovery and time of recovery with varying demand upon the generator. The distance between each peak represents an elapsed time of approximately 0.001 second. Some of the detail in the original oscillograms has disappeared due to the several photographic processes necessary to reduce them to print. None have been retouched for any purpose.

Case Two

An inductive load thrown upon an unloaded machine.

Under these conditions the voltage can never drop to zero, since

$$e = ir + \frac{di}{dt} L_1 \qquad \textbf{(9)}$$

where L_1 is inductance of load.

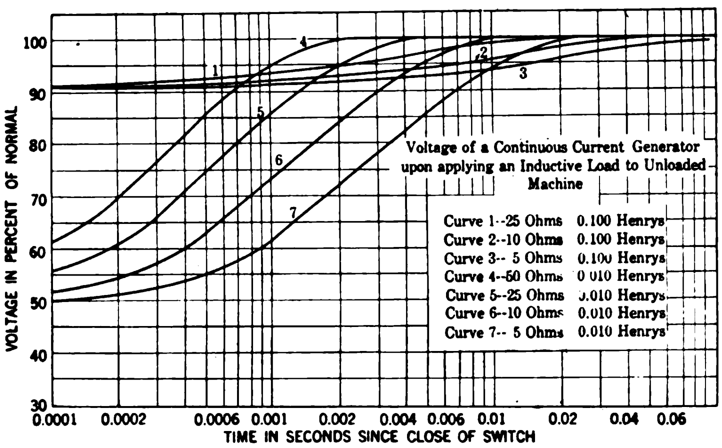

Fig. 3

As in equation (**3**) the current will rise according to an exponential law,

$$i = I(1 - \epsilon^{-\alpha_2 t}) \qquad \textbf{(10)}$$

where
$$\alpha_2 = \frac{r_1}{L_a + L_1}$$

differentiating we get

$$\frac{di}{dt} = \frac{r_1 I}{L_a + L_1} \epsilon^{-\alpha_2 t} \qquad \textbf{(11)}$$

$$= \frac{E}{L_a + L_1} \epsilon^{-\alpha_2 t} \qquad \textbf{(12)}$$

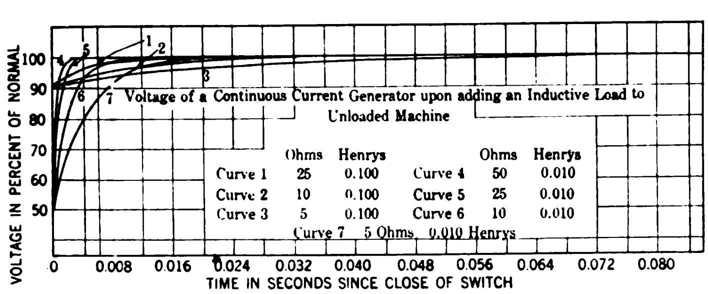

Fig. 4

substituting (**10**) and (**12**) in **9** we get

$$e = E(1 - \epsilon^{\alpha_2 t}) + \frac{L_1 E}{L_a + L_1} \epsilon^{-\alpha_2 t} \qquad \textbf{(13)}$$

which at $t = o$ becomes

$$e_{t=o} = \frac{L_1}{L_a + L_1} E \qquad \textbf{(14)}$$

That is, at the instant of closing the circuit the voltage of the machine divides in the ratio of the inductance of the external and internal circuits, and there is an instantaneous drop to this value. The instantaneous voltage drop depends upon the ratio of the inductances, and is independent of their absolute value, or of the resistance of the circuit. The velocity of return to normal voltage, however, depends, upon the resistance, since at the instant of closing the switch

$$\frac{dt}{dt} = \frac{rI}{L_t}$$

where
$$L_t = L_a + L_1 \qquad \textbf{(15)}$$

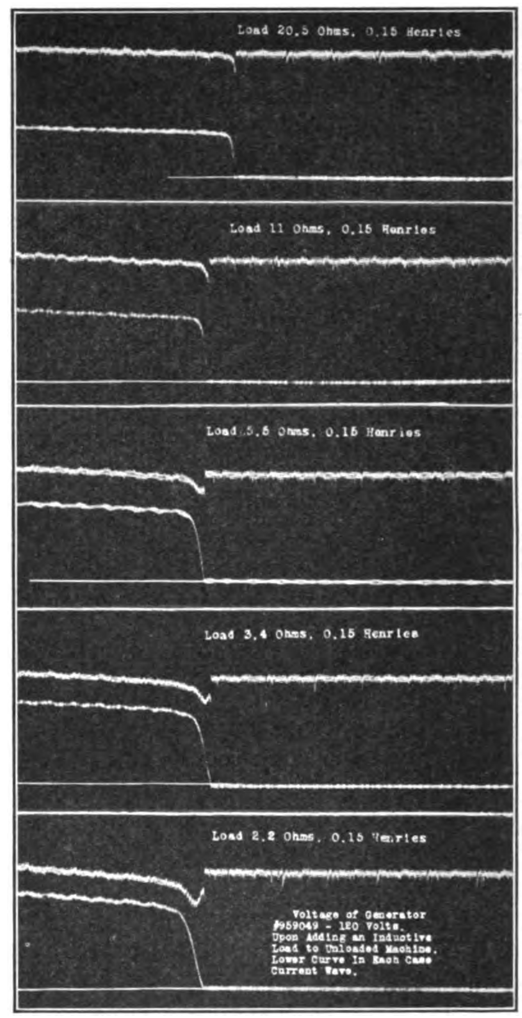

Fig. 5

Fig. 3 is a plot of calculated values on semilogarithmic paper and shows how a change in the value of resistance and inductance of applied load affects the extent of voltage drop and the rate of rise to normal.

Fig. 4 gives the same data plotted on cross section paper.

Oscillograms from tests under several conditions of load are shown in Fig. 5.

Case Three

A non-inductive load added to a machine carrying a non-inductive load.

In this case there is an instantaneous drop of voltage to a value that is equal to the combined resistance of

the circuits, times the current furnished by the machine at the instant of closing the switch,—that is

$$e_{t=o} = \frac{I_1 (r_1 + r_2)}{r_1 r_2} \tag{16}$$

where

r_1 = steady load.
r_2 = added load.

$$I_1 = \frac{E}{r_1}$$

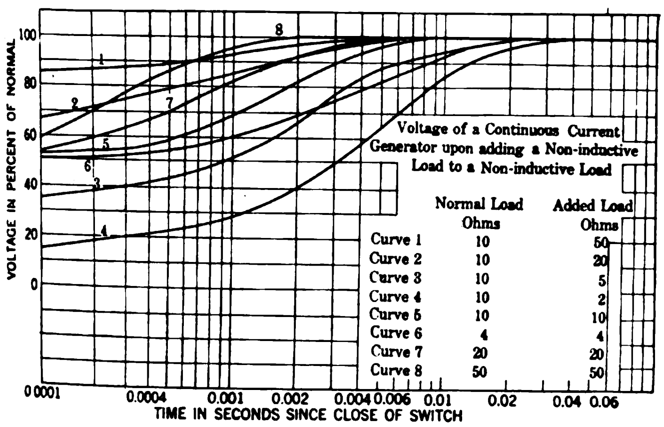

FIG. 6

The current builds up along an exponential law.

$$i = I_1 + I_2 (1 - \epsilon^{-\alpha_3 t}) \tag{17}$$

where

$$I_2 = \frac{E}{r_2}$$

$$\alpha_3 = \frac{(r_1 + r_2)}{r_1 r_2 L_a}$$

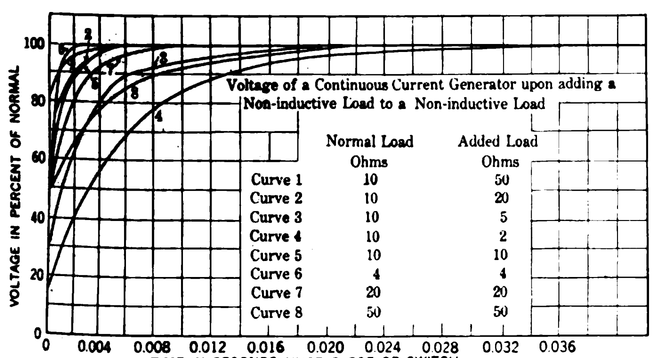

FIG. 7

and the voltage is

$$e = iR \tag{18}$$

where

$$R = \frac{r_1 + r_2}{r_1 r_2}$$

$$e = I_1 R + R I_2 (1 - \epsilon^{-\alpha_3 t}) \tag{19}$$

Fig. 6 is a plot of calculated values to logarithmic abscissas for several values of steady load and added load.

Fig. 7 gives the same data plotted to rectilinear coordinates.

Oscillograms from tests under several conditions of load are shown in Fig. 8.

Oscillograms for similar values of load added to a generator under no load (case one) are shown for comparison.

CASE FOUR

The machine carrying a non-inductive load, and an inductive load added.

In this case there is no instantaneous drop of voltage but the voltage falls on an exponential curve, and rises

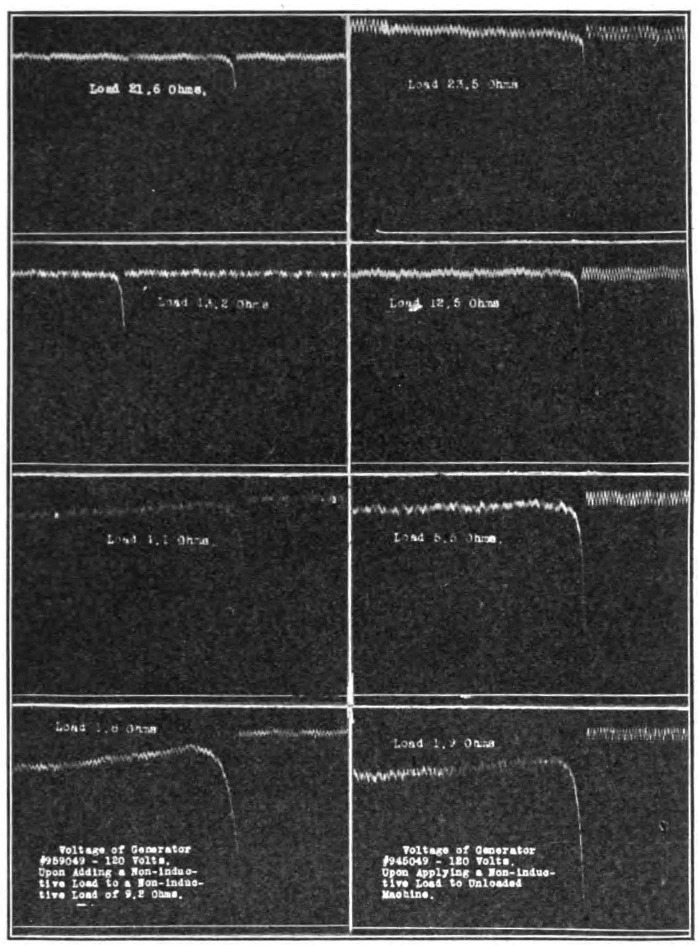

FIG. 8

on a similar curve of smaller exponent value. The voltage across the two branches is alike at every instant and is

$$e = i_1 r_1 = i_2 r_2 + \frac{d i_2 L_2}{dt} \tag{20}$$

where i_1 is the instantaneous value of current in branch 1, i_2 the instantaneous value of current in branch 2. L_2 = the inductance of branch 2.

$$i_1 = I_1 + K\epsilon^{-\alpha_4 t} - K\epsilon^{-\alpha_5 t} \tag{21}$$

where

$$K = (r_2 - \alpha_4 L_2) B$$

where

$$B = \frac{\alpha_5 I_2 - E}{r_1 (\alpha_5 - \alpha_4)}$$

where

$$\alpha_4 = \frac{S - q_1}{2\, L_2\, L_a}$$

and

$$\alpha_5 = \frac{S + q}{2\, L_a\, L_2}$$

where

$$q_1 = \sqrt{S - 4\, r_1\, r_2\, L_a}\, L_2$$

where

$$S = L_a\,(r_1 + r_2) + L_2\, r_1$$

At $t = o$ (**21**) of course reduces to

$i_{1_{t=o}} = I_1$ and the voltage becomes **(22)**

$$e_{t=o} = I_1\, r_1 = E \qquad \textbf{(23)}$$

Fig. 9 is a plot of calculated values for several conditions of steady and added load.

Oscillograms from tests under several conditions of load are shown in Fig. 10 in comparison with similar values of non-inductive load added to a generator carrying non-inductive load. (Case three).

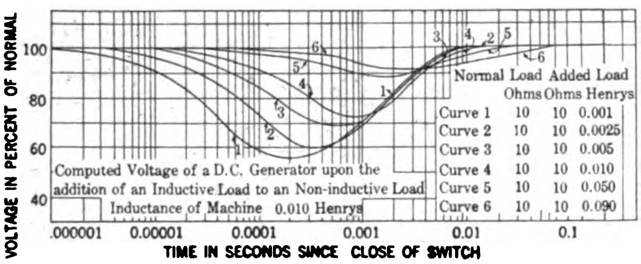

Fig. 9

Case Five

The machine carrying an inductive load, and a non-inductive load added.

In this case there is an instantaneous drop to zero and a building up from there on an exponential curve.

$$e = i_1\, r_1 + L_1 \frac{d i_1}{dt} = i_2 r_2 \qquad \textbf{(24)}$$

where

$$i_2 = I_2 + K_2\, \epsilon^{-\alpha_6 t} + K_3 \epsilon^{-\alpha_7 t} \qquad \textbf{(25)}$$

where

$$\alpha_6 = \frac{S_2 - q_2}{2\, L_a\, L_1}$$

$$\alpha_7 = \frac{S_2 + q^2}{2\, L_a\, L_1}$$

$$S_2 = L_a\,(r_1 + r_2) + L_1\, r_2$$

and

$$q_2 = \sqrt{S^2 - 4\, r_1\, r_2\, L_a\, L_1}$$

$$K_2 = B_2\,(r_1 - \alpha_6\, L_1)$$

$$K_3 = (I_2 + K_2)$$

where

$$B_2 = \frac{I_2}{L_1\,(\alpha_6 - \alpha_7)}$$

Substituting **25** in **24** we get

$$e = r_2\,(I_2 + K_2\, \epsilon^{-\alpha_6 t} + K_3\, \epsilon^{-\alpha_7 t}) \qquad \textbf{(26)}$$

which on equating $t = o$ becomes

$$e_{t=o} = 0 \qquad \textbf{(27)}$$

since in (**26**) both K_2 and K_3 are negative numbers and $-K_2 - K_3 = I_2$.

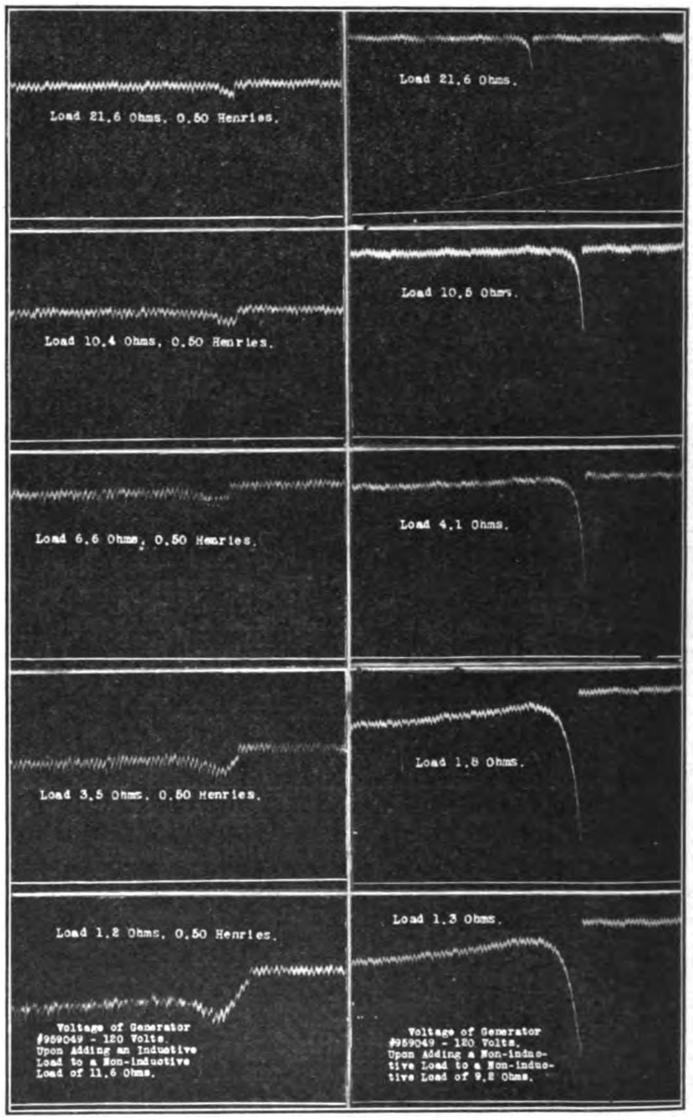

Fig. 10

Fig. 10-A is a calculated plot of several values of load added to a 10-ohm load of variable inductance.

Oscillograms from tests under several conditions of load are shown in Fig. 11 in comparison with similar values of non-inductive load. (Case three.)

Case Six

An inductive load added to an inductive load.

There is in this case an instantaneous drop in voltage, but never to zero. The instantaneous drop is approximately equal to the voltage of the machine, times

the ratio of the added inductance to the sum of the added load and machine inductances. The voltage builds up from this value along an exponential curve of four terms. The current builds up from zero according to an exponential curve of two terms.

$$e_1 = e_2 = i_1 r_1 + L_1 \frac{di_1}{dt} = i_2 r_2 + L_2 \frac{di_2}{dt} \tag{28}$$

$$i_1 = I_1 + K_4 \epsilon^{\alpha_9 t} - K_4 \epsilon^{-\alpha_8 t} \tag{29}$$

where

$$K_4 = B_3 (r_2 - \alpha_9 L_2)$$

$$B_3 = \frac{- I_2 (r_2 - \alpha_8 L_2)}{(r_1 L_2 - r_2 L_1)(\alpha_9 - \alpha_8)}$$

$$\alpha_8 = \frac{S_3 - q_3}{2 L_z}$$

$$q_3 = \sqrt{S_3{}^3 - 4 L_z r_1 r_2}$$

$$S_3 = L_a (r_1 + r_2) + L_1 r_2 + L_2 r_1$$

$$L_z = L_1 L_2 + L_a L_1 + L_a L_2$$

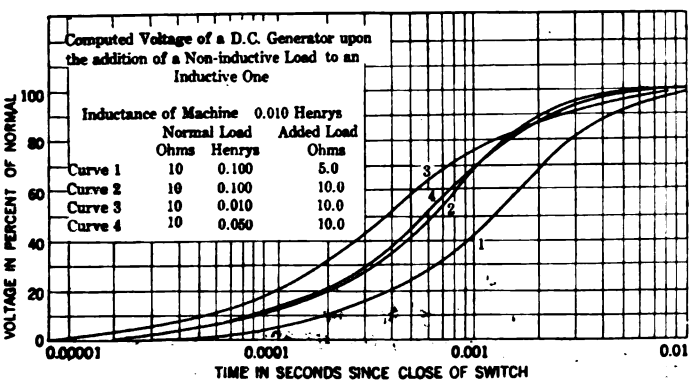

FIG. 10-A

Differentiating (29) we get

$$\frac{di_1}{dt} = - \alpha_8 K_4 \epsilon^{-\alpha_8 t} + \alpha_9 K_4 \epsilon^{-\alpha_9 t} \tag{30}$$

Substituting (29) and (30) in (28) reduces it to

$$e_1 = r_1 \{ I_1 - K_4 [\epsilon^{-\alpha_9 t} - \epsilon^{-\alpha_8 t}] \}$$

$$+ L_1 K_4 (\alpha_8 \epsilon^{-\alpha_8 t} - \alpha_9 \epsilon^{-\alpha_9 t}) \tag{31}$$

This at $t = 0$ becomes

$$e_{1\,t=0} = r_1 I_1 + L_1 K_4 (\alpha_8 - \alpha_9) \tag{32}$$

$$= E + L_1 K_4 (\alpha_8 - \alpha_9) \tag{33}$$

The second term of this expression is always a negative quantity since α_9 is always greater than α_8.

Fig. 12 is a plot of calculated values for several conditions of steady and added load.

Oscillograms from tests under several conditions of load are shown in Fig. 13 in comparison with similar values of inductive load added to a generator carrying non-inductive load. (Case four).

Load Decrements

A load removed from the circuit produces effects opposite to those when load is added, namely, a voltage rise instead of dip.

It is well-nigh impossible to express mathematically such cases or analyze them experimentally, due to our inability to assign proper value to the increasing resistance of the arc that forms when the load is removed.

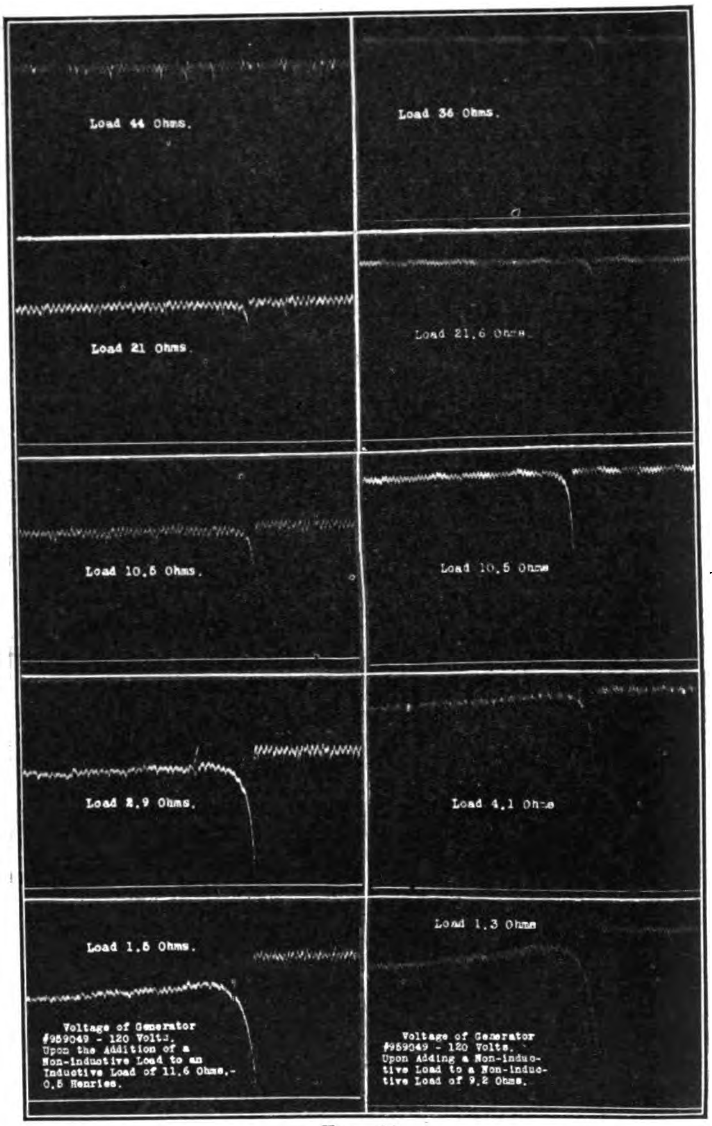

FIG. 11

Conclusion

The foregoing equations can of course be at best but first approximations especially at values well along the recovery curve. No allowance has been attempted for the variation of permeability with flux density, or for the individual characteristics and reactions of machines themselves. However, the equations will be found valuable and reliable for the computation of voltages near the start of the transient, which should make them of value in the determinations of those conditions that would cause flicker of lamps upon the loading of a generator or circuit.

The principles and equations already laid down lead

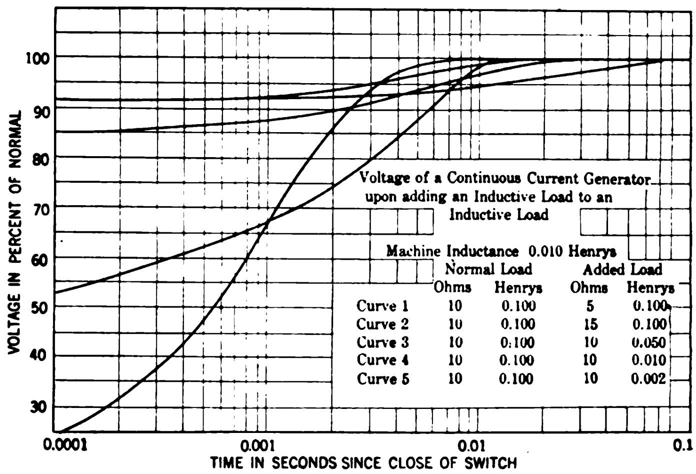

Fig. 12

to some rather unusual conclusions regarding the means of improving the instantaneous regulation of circuits where flickering of lamps is objectionable. The voltage changes that have been discussed are inherent in such circuits, and in general, in large measure are independent of the cross section of feeder or service lines. No matter how large the cross section there will be a voltage dip that is inherent in the circuit, and if the inductance of the series circuit is large enough the application of a load will cause flicker. Being dependent upon the inductance of the circuit for their duration, attempts at their elimination by the compounding of machines are obviously steps in the wrong direction. Better instantaneous regulation will be obtained from shunt machines, than from compounded ones due to the lesser inductance of the former. Not only does compounding lead to a greater duration of transient conditions but the extra windings have no effect on the generated voltage of the machine until the current has risen well along the recovery curve.

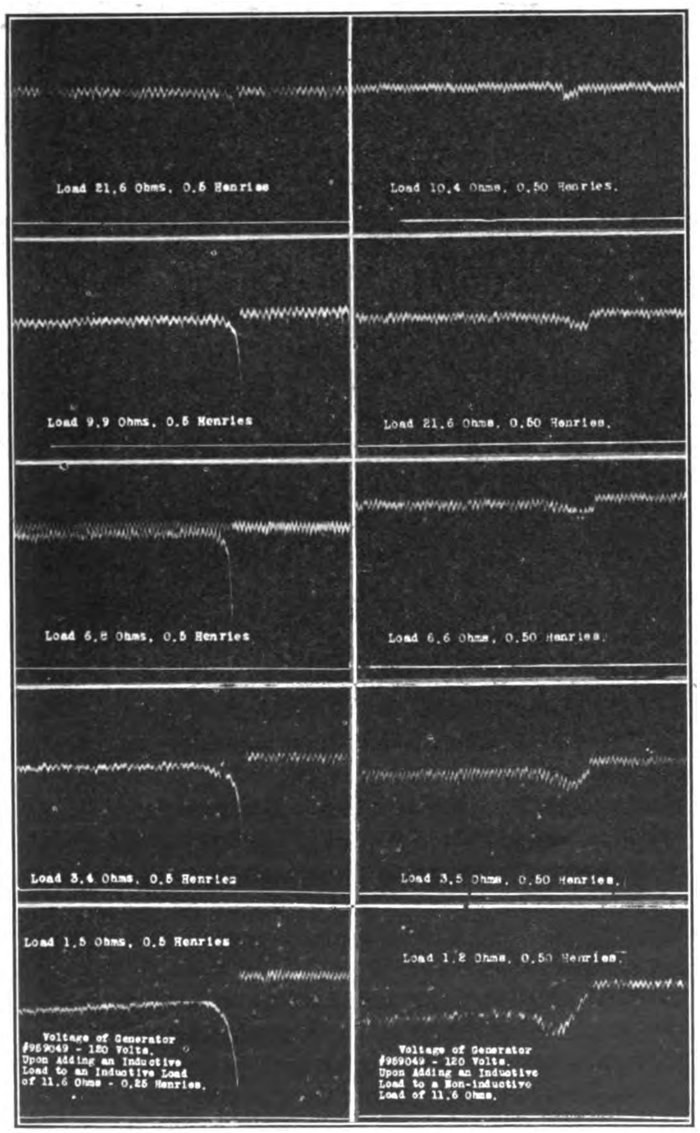

Fig. 13

The disturbances of large loads applied to lines can be mitigated by the insertion of suitable values of inductance coils of low resistance in series with the applied loads. In general the larger the value of the inductance applied the smaller will be the effect of a given load on the rest of the line. The fundamental principles involved in this application were discussed under the second case of load increments. It was there shown that the greater the ratio of the applied inductance to the machine inductance, the less will be the instantaneous drop. The other cases, that of inductance added to loads already on the lines, follow this same principle though the analytical treatment of them is not so simple.

RESEARCH GRADUATE ASSISTANTSHIP

The University of Illinois maintains fourteen Research Graduate Assistantships in the Engineering Experiment Station and two other assistantships have been established under the patronage of the Illinois Gas Association. These assistantships, for each of which there is an annual stipend of $500 and freedom from all fees except the matriculation and diploma fees, are open to graduates of approved American and foreign universities and technical schools.

An appointment to the position of Research Graduate Assistant is made for two consecutive collegiate years, at the expiration of which the degree of Master of Science will be conferred. Not more than half of the time of a Research Graduate Assistant is required in connection with the work of the department.

Nominations to these positions are made from applications received by the Director of the Station each year not later than the first day of March. Preference is given those applicants who have had some practical engineering experience following the completion of their undergraduate work.

The work of the Engineering Experiment Station is closely related to that of the College of Engineering, and the Heads of Departments in the College constitute the Executive Staff of the Station.

Additional information may be obtained by addressing the director, Engineering Experiment Station, University of Illinois, Urbana, Illinois.

Oscillograms and their Tests

BY A. E. KENNELLY, Professor of Electrical Engineering, Harvard University, and the Mass. Inst. of Technology

R. N. HUNTER, Engineering Department, American Telephone and Telegraph Co.

and A. A. PRIOR, Instructor Case School of Applied Science

OSCILLOGRAPHS, as used in electrical laboratories, are divisible into two classes; namely, first, those that employ mechanical vibratory systems, and second, those that employ no mechanical vibratory systems. In the first class, are the great majority of electrical engineering oscillographs. In the second class are Braun cathode-ray tubes. The paper here presented deals only with the first class, or mechanical vibrators.

All mechanical-vibrator oscillographs behave differently to different frequencies, owing to their inherent elasticity and inertia. In other words, their specific deflections[1] and calibrations differ at different frequencies. These differences affect both magnitude and phase. An oscillograph calibrated at, say, 60～ must have a different calibration at other frequencies. In some instruments, the difference may be small, and for many purposes it is often negligible. In other instruments, or for other purposes, the difference may be very serious. But whether the error due to a change in frequency is small or large, it should be measurable, and the amount of it should be either known or determinable to the desired degree of precision.

When the oscillogram of a complex alternating wave form is analyzed, in one of the usual ways, for its Fourier components; *i. e.*, into a fundamental wave and its harmonics, these different harmonics call for their proper corrections, both as to amplitude and to relative phase position. It is not possible for the same calibration to apply to them all. If the instrument has been calibrated at, or near, the fundamental frequency, the apparent harmonic components require correction. The correction factors may be greater or less than unity. They may not be serious, but they should be capable of determination.

These errors of harmonic analysis in oscillograms have been known for some years, as the bibliography of the paper indicates; but no technique for determining the correction factors of an oscillograph at various impressed frequencies has yet been published, so far as the authors are aware.

The paper discusses (1) the theory of an oscillograph with relation to the purpose in view, (2) a device called an oscillograph-meter, which is an auxiliary compact vibrator for determining the resonant frequency of the tested oscillograph, and (3) a number of measurements obtained in this way upon oscillographs in the laboratory.

Theory. The paper points out that there is a complete and valuable analogy between an oscillographic vibrator, or the working part of an oscillograph, and a simple alternating-current branch circuit ($C\ L\ R$ circuit), containing a fixed capacitance C, a fixed inductance L, and a fixed resistance R, all in series across a pair of constant-potential mains, operated at variable impressed frequency. The capacitance C corresponds to the looseness or inelasticity of the mechanical suspension, the inductance L to the mechanical moment of inertia, and the resistance R, to the mechanical torque of frictional resistance to motion in the vibrator. Again, the alternating e.m.f. of the mains corresponds to the alternating torque imposed by a given r. m. s. current passed through the vibrator, and the alternating current strength in the $C\ L\ R$ branch to the angular velocity of the vibrating mirror. This analogy is helpful, because electrical engineers are more likely to be familiar with the electromagnetics of alternating-current circuits than with the dynamics of vibratory mechanical systems.

What the oscillographer desires to ascertain is the maximum angular displacement of the vibrating mirror under constant impressed vibratory torque, but with variable frequency. This displacement bears the same relation to vibratory angular velocity that alternating quantity, or electric displacement in the $C\ L\ R$ branch, bears to alternating current.

It is shown that just as there is the well known impedance Z to alternating current in a $C\ L\ R$ circuit, such that, by Ohm's law, $I = E/Z$; so there is also an impedance Z' to alternating electric quantity, or electric displacement, such that the maximum cyclic displacement is E/Z'. Attention is therefore directed to this "displacement impedance" in a simple branch circuit, which corresponds, in the mechanic analogy, to displacement impedance in the oscillograph.

Bluntness of Resonance. Any mechanical oscillograph, like any $C\ L\ R$ branch circuit, has a certain "bluntness of resonance" B. This quantity may be defined in various ways; but the definition selected in the paper is the ratio of the damping factor to the resonant angular velocity. A vibrator, or a branch circuit, has a bluntness of unity, when its resistance is just sufficient to make it critically aperiodic. If the bluntness is, say, 0.5, then the resistance is half that necessary for critical aperiodicity. Such a vibrator, or circuit, would have a "sharpness of resonance" of $1/0.5 = 2.0$. A bluntness of $B = 3$ would mean three times as much resistance as would be necessary for critical aperiodicity. An air-damped oscillograph ordinarily has a very small bluntness, or a large sharpness of resonance ($B = 0.01$ perhaps). A vibrator damped in castor oil may, on

1. The specific deflection of an oscillograph may be defined as the ratio of its deflection to the r. m. s. current producing the same.

Abstract of a paper to be delivered at the Midwinter Convention of the A. I. E. E., New York, February 20, 1920.

the other hand, have a bluntness greater than unity ($B = 1.2$ perhaps). The most suitable bluntness for an oscillograph, in order to operate with uniformity over a wide range of frequency, is probably near $B = 0.6$. The best value depends on the range of frequency to be covered.

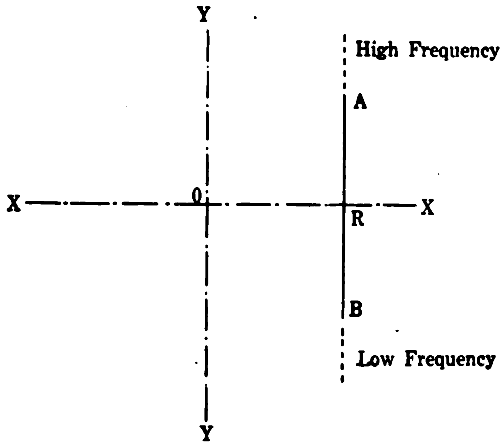

FIG. 1—VECTOR LOCUS OF IMPEDANCE TO ALTERNATING CURRENT IN A $C\ L\ R$ BRANCH, OR TO ANGULAR VELOCITY IN A VIBRATOR

If the resonant frequency f_0 of an oscillograph, and its bluntness B_0, are known, then its correction factor as regards amplitude and phase can be readily computed or tabulated for any or all impressed frequencies.

Displacement Impedance. Whereas the impedance Z of a branch circuit to electric current, at varying

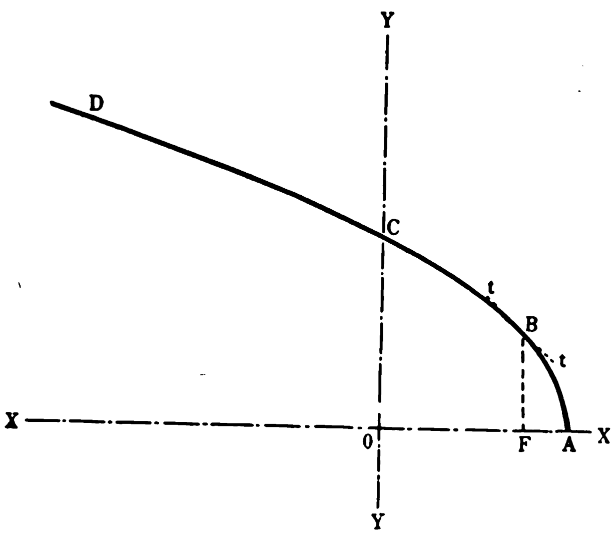

FIG. 2—VECTOR PARABOLIC LOCUS OF DISPLACEMENT IMPEDANCE IN A $C\ L\ R$ BRANCH CIRCUIT OR IN A VIBRATOR

impressed frequency, is a straight line, $A\ R\ B$ Fig. 1, parallel to the Y axis, and passing through the point R on the resistance or X axis at the resonant frequency, the impedance Z' of the branch, to displacement, is a simple parabola $A\ B\ C\ D$ Fig. 2, having its axis on the real axis $X\ O\ X$. At zero frequency, the displacement impedance is $O\ A = 1/C$, and is equal to the reciprocal of the capacitance. As the impressed frequency increases, the vector displacement impedance is OB, OC, OD, and so on. At resonance, it is OC, along the Y axis. The focus F of the parabola lies below the point B, at which the tangent $t\,t'$ is equally inclined to the X and Y axes. Branches or vibrators of sharp resonance have a sharp vector displacement-impedance parabola, and the focus F lies to the right of the origin O. Branches or vibrators of blunt resonance, have a blunt displacement-impedance parabola, and the focus F lies to the left of the origin O. The ratio of the ordinate $F\ B$ through the focus, to the ordinate $O\ C$ through the origin, is equal to the bluntness B_0 of the branch or vibrator.

Displacement Admittance. If we plot the reciprocal of the parabolic vector displacement impedance, we obtain a "displacement admittance" curve, or reciprocal of a parabola, which indicates the magnitude and phase of the displacement produced by unit impressed

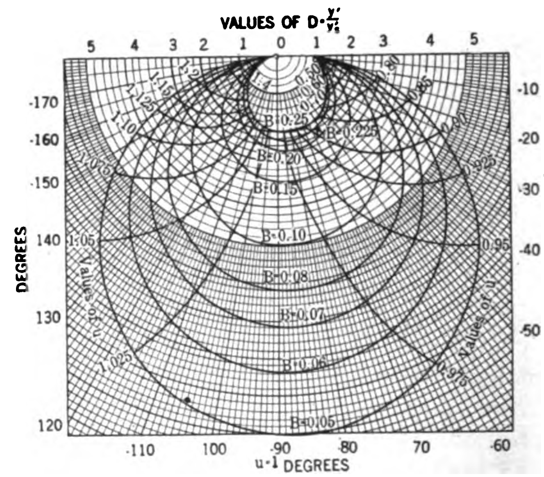

FIG. 3—PLANEVECTOR CHART OF THE DEVIATION FACTOR D FOR ANY OSCILLOGRAPH WHOSE BLUNTNESS LIES BETWEEN $B = 0.25$ AND $B = 1.0$, AND WHOSE RESONANT FREQUENCY IS GIVEN.

EXAMPLE: IF $B = 0.6$, AND $u = 0.3$,
THEN $D = 1.022 / 21.6$ DEG.

e. m. f. in the branch circuit as the impressed frequency is varied. A group of these curves are presented in Fig. 3, between the limits $B = 0.25$ and $B = 1.0$, for various ratios u of impressed to resonant frequency. From these curves, the behavior of any ordinary oscillograph can be read off, by inspection, when the bluntness B, and the resonant frequency f_0 of its vibrator are known. Thus, an oscillograph of bluntness $B = 0.3$, and calibrated at, or near, 60~, would over-indicate in the ratio 1.24 $\nwarrow$ 22 deg. at $0.5\,f_0$, or at an impressed frequency half of its resonant frequency. Its maximum cyclic deflections would be 24 per cent too great at this frequency, and they would lag 22 deg. in phase behind the impressed torque. At $0.8\,f_0$, it would over-indicate in the ratio 1.65 $\nwarrow$ 53 deg., and so on, following the curve for $B = 0.3$.

Technique for Measuring f_0. In order to measure the resonant frequency, which, as indicated in Fig. 3,

is not the frequency of maximum displacement, an optical method is used; *i. e.*, the method of Lissajous figures. An auxiliary permanent-magnet air-damped vibrator, shown in Fig. 4, is supported close in front of the tested oscillograph vibrator, as in Fig. 5. Both vibrators are connected to the same high-frequency source—a Vreeland oscillator or triode vacuum-tube oscillator. The frequency impressed from this source

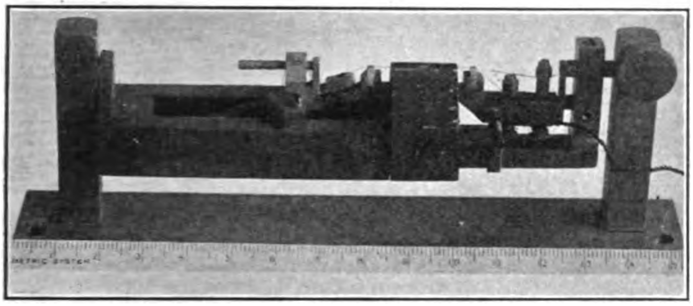

FIG. 4—OSCILLOGRAPHMETER OR AUXILIARY VIBRATOR, LENGTH OF MIRROR 2.3 MM. BREADTH 0.9 MM.

on the vibrators is raised, until the resonant frequency of the tested oscillograph is reached. Then, provided that the auxiliary vibrator is not also nearly resonant, the phase displacements of the two mirrors will be in quadrature. At resonance, the phase of a vibrator always lags 90 deg. behind the impressed torque. The auxiliary vibrator mirror, being air damped, and of very sharp resonance, will be very nearly in phase with

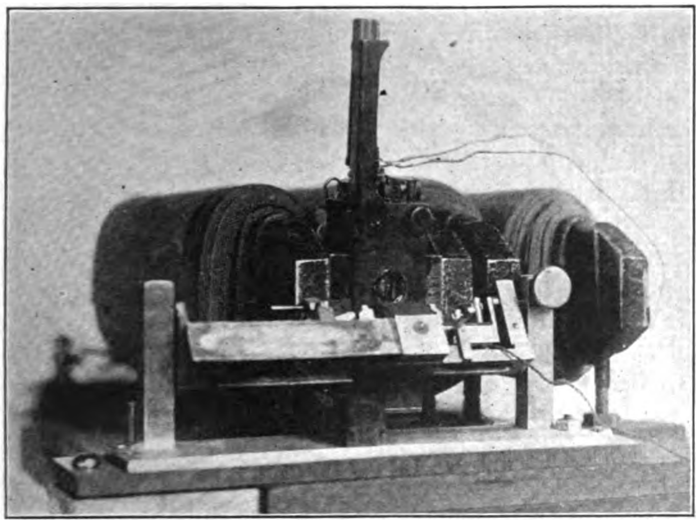

FIG. 5—OSCILLOGRAPHMETER APPLIED TO OSCILLOGRAPH FOR TEST OF LATTER

the impressed torque until the impressed frequency is close to its resonant point. The condition of quadrature between the two vibrating mirrors is easily detected, by throwing a small arc-light beam, first on to the tested vibrator mirror, and then to the auxiliary vibrator mirror, and finally on a fixed screen, the two mirrors having their axes mutually perpendicular. The optical figure perceived on the ground glass or paper screen reveals the quadrature relation.

Technique for Measuring B. Having ascertained the resonant frequency f_0 for the tested oscillograph, as above described, the auxiliary vibrator is withdrawn, and the tested oscillograph is then calibrated at any very low frequency, such as 60~, and again at its resonant frequency f_0. The ratio of the specific deflection at 60 ~, to twice the specific deflection at f_0 is then the bluntness B of the vibrator. This relation can be observed from an inspection of Fig. 3.

Having thus ascertained the fundamental constants f_0 and B of the oscillograph, its behavior at any impressed frequency may be ascertained, either by graphic approximation from Fig. 3, or by means of a formula given in the paper. These fundamental constants f_0 and B should be measured, whenever an oscillogram of a periodic wave form is secured for accurate work, and they may advantageously be recorded, for reference, on the oscillogram itself. Both constants are subject to variation with the temperature of the damping liquid; but, at constant temperature, they appear to be fairly permanent.

Results of Observations. The observations above described have been checked upon a number of vibrators, with satisfactory results. Oscillographic vibrators have resonant frequencies ordinarily lying between 1200~ and 5000~. Their bluntness B depends very largely upon the viscosity of the damping liquid. A vibrator, for example, which in air, had $f_0 = 2635\sim$ and $B_0 = 0.055$, developed in glycoline $f_0 = 1675\sim$ and $B_0 = 0.125$. In mineral oil, these values became $f_0 = 1614\sim$ and $B_0 = 0.288$; while in castor oil, they became $f_0 = 1196 \sim$ and $B_0 = 0.83$.

Tables and curves are presented in the main paper, giving the results obtained on various instruments in the laboratory.

SLAG AS AN AGGREGATE FOR CONCRETE

The results of the investigation made by the Bureau of Standards during the past two years on this subject are summarized as follows: Crushed slag as a coarse aggregate produced concrete of as high or higher strength than gravel. The tests have not been extensive enough to determine the durability of slag, but so far as they have gone, no signs of disintegration have been observed due to sulphide sulphur. Slag sand, because of its lack of fine material, does not produce easily workable concrete when used as fine aggregate. If it must be used, its working qualities can probably be improved by the addition of small amounts of fine sea sand, hydrated lime, or other similar material. In all probability, a larger amount of fine aggregate to replace some of the coarse aggregate would aid workability. Provisions in specifications for slag aggregates calling for a maximum sulphide sulphur content of 1½ per cent and a minimum weight per cubic foot of 70 pounds have been tentatively recommended.

Daylight Saving

BY PRESTON S. MILLAR

General Manager, Electrical Testing Laboratories, New York

"Daylight Saving" is found to reduce the total output of certain central stations and of one gas company by about 3 per cent during the seven summer months. Reduction in output for lighting alone is found to average 8 per cent. Applying these fragmentary data to the country as a whole there is estimated an annual saving by the public of $19,250,000 in expenditure for artificial light and a reduction of about 495,000 tons per annum in consumption of coal.

The principal advantages of "Daylight Saving" are promotion of outdoor recreation, saving in expenditure for artificial light and saving of fuel. Disadvantages are experienced principally by farmers, dairymen, truck gardeners and miners. Economic losses probably far outweigh the gains.

Custom in allocating hours for work, sleep and play has been evolved through experience. It is undesirable to alter it by arbitrary legislation. Since advancement of clocks, while serving the interests of one part of the population, has proved so disadvantageous to another part as to compel return to correct time, it seems obvious that those who benefit by advanced time in summer should adjust their habits as desired without disturbing the practise of the remainder of the population.

IN accepting the invitation of the Lighting and Illumination Committee to present a paper on "Daylight Saving," the author stipulated that in order to consider the subject comprehensively, a considerable part of the paper would have to be devoted to matters remote from electrical engineering. The economic and sociological aspects of daylight saving surpass in importance the effect upon use of artificial light. Any treatment which should ignore these important features would lack perspective and would be likely still further to increase confusion on a subject which is greatly in need of clarification. Accordingly this paper includes a brief survey of daylight saving in its several aspects.

Postponing for the latter part of the paper discussion of the advantages and disadvantages of daylight saving, consideration is first given to the effect upon output of electric plants and upon use of artificial light.

PART I

Reduced Use of Electricity

Effort has been made to secure from central stations and from private plants information which will indicate the effect of daylight saving upon output.

No organized data concerning private plants have been located.[1] The general view of those best informed seems to be that the saving is not of great moment.[2]

Statistics have kindly been supplied by several large central station companies. This opportunity is taken to express the author's appreciation of the cooperation accorded in this connection. These companies operate in the northeastern part of the United States in the region bounded on the south by the Potomac and Ohio Rivers (roughly 38 deg. N.) and on the west by the Mississippi River. Differences in latitude within this region are considerable and doubtless have an appreciable effect upon the use of artificial light. Differences in longitude may of course result in something like one hour greater or less use of artificial light, depending upon location east or west of the meridian with reference to which local time is fixed. However, the variable conditions under which these stations operate and the fluctuations in weather conditions are such as to make impracticable a detailed analysis with reference to latitude and longitude.

The central station statistics have been compiled partly from comparison of output in the years prior to 1918 with the two more recent years, allowance being made for growth of business, and partly from study of daily load curves and daily kilowatt-hours just before and just after change of clocks at the beginning and at the end of the daylight saving periods of 1918 and 1919. Such daily load curves have been reduced to percentages of total daily send-out and have been combined to obtain the composite curves shown respectively in Figs. 1, 2, 3 and 4. The autumn curves differ from the spring curves characteristically due in part to earlier darkness. Beyond this the several composite load curves bear no inter-relation being formed from the data made available for each period of time change, and including in each case different groups of central stations. It is not significant for our purpose, for example, that the ratio of day to evening peak in Fig. 3 is greater than that in Fig. 1. It is significant, however, that in spite of the independence of the four curves they exhibit certain features in common. There is a slight increase in consumption in the early morning under advanced time; a conspicuous valley in the evening; a later and diminished evening peak; and in most cases a slightly increased output in the late evening. The daily load factor is not affected in cases where industrial power absorbs the maximum output. For lighting, as shown later, the output is reduced to about the same extent as the lighting maximum and therefore the daily load factor for such loads is not materially influenced.

In Table I there is a summary of the central station statistics which enter into the construction of the composite load curves in Figs. 1 to 4 inclusive. These

To be presented at the 8th Midwinter Convention of the A. I. E. E., New York, February 18, 1920.

1. For references see end of paper.

show for the time of advancing or retarding clocks in both 1918 and 1919, the number of central stations contributing statistics and the average changes in daily send-out for the entire plants. Certain other information not attributable to particular dates is included as "miscellaneous."

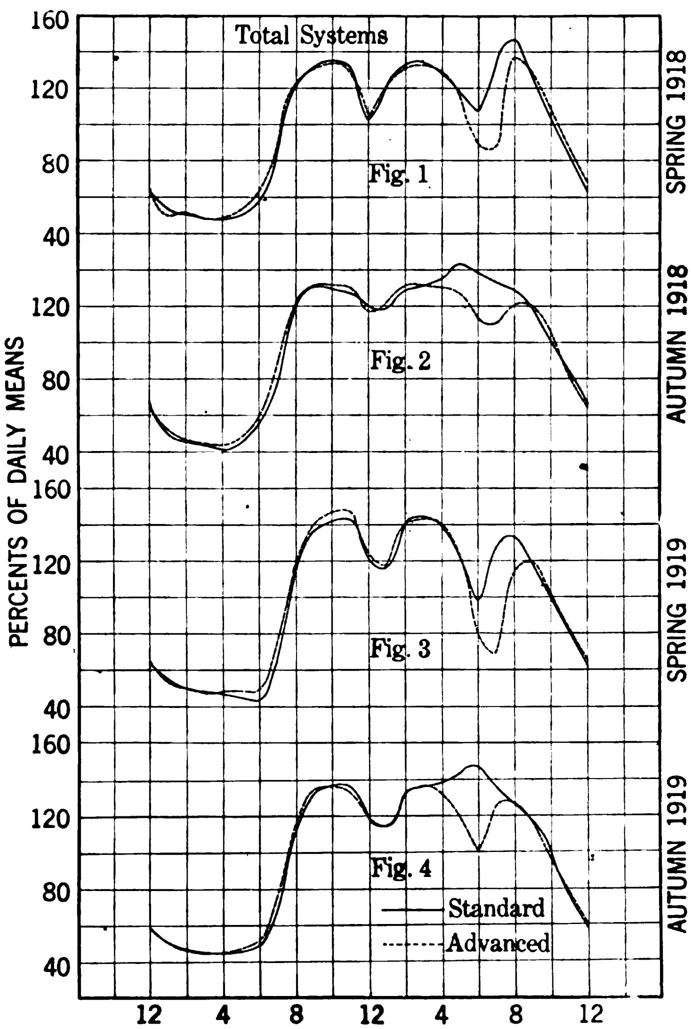
TABLE I
Change in Weekday Output of Central Stations under Daylight Saving

Period	Number of companies	Differences	
		Range	Average
Spring, 1918	16	+ 0.3 to − 9.0	− 3.0
Autumn, 1918	4	+ 4.4 to − 5.7	− 2.0
Spring, 1919	6	+ 3.4 to − 8.0	− 2.5
Autumn, 1919	7	+ 0.7 to − 6.3	− 3.1
Miscellaneous	4	− 0.8 to − 5.5	− 2.4

Variations due to other causes are greater than the average reduction due to daylight saving, some data actually showing increases of output for certain days under daylight saving. The differences are derived principally from comparison of equivalent weekdays ranging in number from one to five before and after change of clocks. No allowance has been made for the natural decrease in use in the first week of advanced time in April as compared with the last week of standard time in March, nor for the corresponding actual increase in use under normal time in the first week of November as compared with that of the last week of October. The effect of ignoring this variable in both cases is slightly to exaggerate the indicated reduction in use of electricity due to daylight saving.

The average data for the several periods yield reasonably concordant indications as to the extent of the effect upon daily send-out at the beginning and end of advanced summer time. The average reduction in daily kilowatt-hours is shown to be of the order of 3 per cent. There is reason to believe that in the interval between these periods the reduction is not markedly different. Accepting 3 per cent therefore as representative of the extent to which in our general latitude during the seven summer months the kilowatt-hour output of central station plants is decreased, it is possible to form a rough estimate of the amount of coal saved by central stations and of the amount of money saved by the public through the less use of electric light.

In ordinary circumstances good judgment would probably dictate that one refrain from hazarding estimates of these kinds due to the inadequacy of information and to the wide range of conditions throughout the country, many of which depart materially from the conditions of operation of the companies included in this survey. Much unreliable information has been published, however, purporting to indicate the extent of saving in fuel and money growing out of advanced summer time, and it would appear desirable therefore to offer a reasonable estimate based upon the data here made available. In undertaking to do so it is to be emphasized that the data in this paper are quite meager. Of the many central stations in the country only a very few are represented. In consequence these estimates are to be regarded as only rough approximations which are probably well indicated by the available information but which may depart considerably from real accuracy when made the basis of assumptions for other localities or for the country as a whole.



Estimate of Reduction in Expenditure for Electric Light.

One estimate of saving to the public in cost of electric light is made by estimating the total output of central stations, under normal time, considering 3 per cent to have been saved, and assuming a rate of six cents per kilowatt-hour as applicable to such savings. Another estimate is made by pro-rating over the entire country estimates of total annual savings in particular cities.

Estimated total annual output of steam central stations for light and power if normal time had prevailed in 1918 or 1919[3]	14,375,000,000	kw-hr.
Ditto for seven summer months	8,000,000,000	"
3 per cent of above	240,000,000	"
At six cents		$14,400,000

	Range	Mean
Published estimates per capita[4]	21 cents to 24 cents	22 cents
Private estimates per capita[5]	14 cents to 21 cents	19 cents
Assigned		21 cents

Estimated total annual savings at 21 cents of 60,000,000 people in communities served by steam and water plants	$12,600,000
Assigned annual value of reduced expenditure for electric light supplied by central stations	$14,000,000

How much of this is to be considered actual saving to the public is an unanswered question. The long

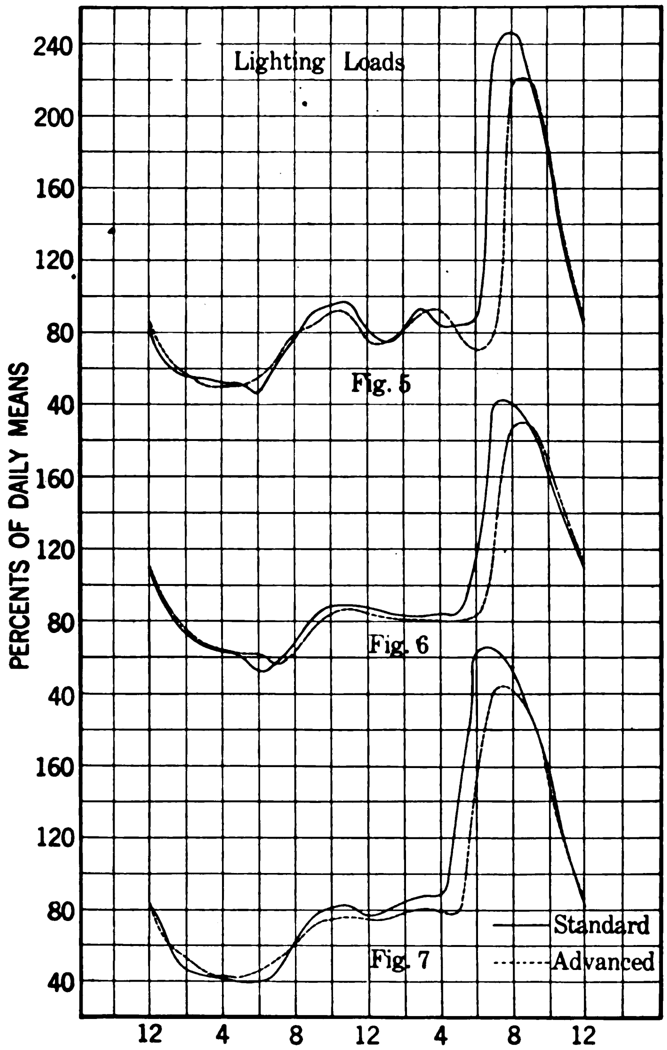


Fig. 5
Fig. 6
Fig. 7

continued downward trend of rates for electricity was halted by increased costs growing out of the World War. The effect upon central stations of daylight saving has been in a small way to reduce revenues from electric lighting without affording opportunity for compensating reductions in cost. This has contributed to a very slight extent to halting the downward course of rates and to bringing about increases in rates here and there, where these have been found necessary. Furthermore minimum rates for service in force in many localities limit the reduction to smaller amounts than those entering into the foregoing estimate. In view of these conditions it is a question what part of the $14,000,000 estimated to be the aggregate reduction in payment by the public for electric light should be considered to be an actual saving to the public.

Saving in Coal. Taking the above estimate of kilowatt-hours as the annual reduction in output of central stations due to daylight saving, and estimating a coal saving rate of say 2½ pounds per kilowatt-hour, we arrive at an estimate of 300,000 short tons of coal saved per annum.

Reduction in Residential Use of Electricity. All of the foregoing has been based upon statistics as to the total daily send-out of central station plants. It is in residential lighting that the effect of daylight saving is most conspicuous. Through the courtesy of certain central station companies it has been possible to obtain information as to the daily kilowatt-hours and daily load curves of certain substations or feeders which are devoted largely to the supply of residential districts, and certain Sunday records which are of a somewhat similar character. These have been consolidated and are presented in Figs. 5, 6, and 7. The valley in the late afternoon occasioned by daylight saving is again seen, the shifting of the peak and the decrease of the maximum are evident and there is exhibited a tendency for people to use light to a later hour according to the clock than under normal time, thus indicating a tendency to sit up later. In passing it may be noted that certain telephone statistics in the spring of 1918 tended to confirm this conclusion.

Statistics accompanying daily load curves for residential service are summarized in Table II.

TABLE II
Change in Output of Central Stations for Lighting under Daylight Saving

Period	Number of companies	Differences: Range	Differences: Average
Spring, 1918	4	− 2.0 to − 19.0	− 9.0
Spring, 1919	5	− 5.3 to − 9.1	− 7.0
Autumn, 1919	3	− 5.0 to − 12.6	− 8.5
Miscellaneous	2	− 7.0 to − 7.0	− 7.0

The principal interest in this connection has to do with reduction in the use of artificial light under daylight saving. The indication here is that by and large this amounts to approximately eight per cent in residences.*

*R. S. Hale, *Electrical World*, January, 1920 estimates for Boston residence customers paying $100 per annum a saving of 8.3 per cent and for residence customers paying $20 per annum a reduction of 6.8 per cent during the 7 summer months.

An interesting further study of the reduced residential use of electricity due to daylight saving is afforded through statistics kindly supplied by one central station company to show average kilowatt-hours per residence during each month of the years 1916 to 1919 inclusive. (1919 up to October; estimated for November and December). These are analyzed by a method growing out of a suggestion by Mr. W. F. Wells. The monthly kilowatt-hour averages for 1916 and 1917, prior to the daylight saving period, have been combined and reduced to percentages of the mean monthly value. A like course has been followed in analyzing the 1918-1919 statistics. To the latter, however, a uniform factor has been applied reducing the monthly values to equality for the average of the five winter months with the average of those of 1916-1917. Thus the two curves coincide approximately for the winter months and departures during the seven summer months may reasonably be considered to have been

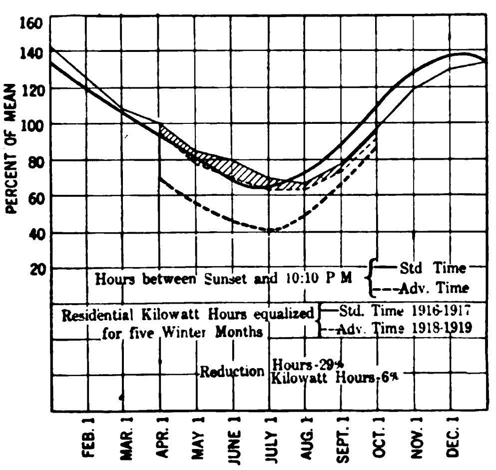

Fig. 8.—Effect of Advancing Clock by One Hour (Latitude 40° N.)

due to daylight saving. For comparison the elapsed time between the hour of sunset (latitude 40 degrees north) and 10:10 p.m. has been taken. This is chosen with a view to making the range of artificial lighting hours employed in this analysis co-extensive with the range in monthly kilowatt-hours. Incidentally, for the beginning and end of the daylight saving period these hours of artificial lighting are found to center fairly well upon the evening peak as indicated in Figs. 5 to 7. In Fig. 8 the hours of artificial lighting thus chosen are indicated by the heavy continuous curve for the several months of the year. The reduction in such hours occasioned by the advancement of the clock in summer time is indicated by the broken heavy line. Both are expressed in per cent of the yearly mean of such hours of artificial lighting. This shows that advancement of the clock during the seven summer months means a reduction by 29 per cent in the evening lighting hours. The light continuous line indicates relative monthly kilowatt-hour consumption of residences in 1916-1917. The relative consumption during the daylight saving period is indicated by the light broken line. The reduced use during this period is represented by the cross-hatched area. This indicates for the city represented in this analysis a reduced use in residences of six per cent.

Reduced Use of Gas

As the preparation of this paper approached completion, it was suggested that a useful purpose would be served by including some information to show the reduction in use of artificial gas due to daylight saving. Hurried requests to a gas company for information met with cordial and prompt response, as a result of which the author was kindly given access to the records of gas send-out. The company operates in the same general region described for electric companies.

In the gas business ordinary variations of output from day to day greatly exceed in magnitude any effect to be anticipated from daylight saving. These fluctuations are so marked and so difficult of explanation as to deter those in responsible positions in the industry from hazarding an estimate of the effect of daylight saving—a view which the records show to be based upon sound engineering judgment. The author, however, after studying the records of this gas company with considerable care, has arrived at an estimate which he feels justified in putting forward as his opinion for which the officials of the company are in no way responsible.

Reduced Use of Artificial Gas. Resorting to graphic analysis it has been possible to extort from apparently inconsistent data of send-out at the time of change of clocks an indication as to the effect of daylight saving. In the case of this one company there is indicated a reduction of about three per cent in the total gas output per day due to daylight saving. It is interesting to note that this entirely independent estimate is closely in accord with the average assigned for reduction in use of electricity. The author assumes that the three per cent indicated as the reduction at the beginning and end of the daylight saving period, as in the case of electricity, is fairly representative of the effect during the intervening months. It is equivalent to about 1½ per cent for the year as a whole.

Coal Saved Through Reduced Use of Gas. It has been estimated that in a year preceding the introduction of daylight saving the net consumption of coal in the manufacture of gas aggregated 10,500,000 short tons.[6] If an increase to 13,000,000 be assumed for a daylight saving year, and if one-half that amount be attributed to the seven summer months, there is a total of 6,500,000 tons, 3 per cent of which gives 195,000 tons as a rough estimate of coal saved. An additional reduction was of course effected in the use of oil.

Reduced Expenditure for Gas. A U. S. Government report for 1915[7] estimated the annual manufacture

of artificial gas to be 284 billions cubic feet. Assuming that for a daylight saving year this was increased to 350 billions, one-half of which was produced during the seven summer months, and using the estimate reached in this paper of three per cent reduction, there is indicated a saving which at $1.00 per thousand cubic feet equals $5,250,000.

Summary of Effect upon Use of Artificial Light

In asking indulgence for the inadequacy of data entering into these estimates the author begs to submit that he is not directly associated with either of the industries affected but must request from them statistics which are necessary for this purpose. In thus imposing upon the good nature of others it was in order to exercise some restraint, requesting information which might be readily available instead of asking for particular details the procuring of which might involve much effort and cost. The material which has been so courteously offered is believed to be reliable and representative. If by reason of its inexhaustive nature or because of poor judgment of the author in its analysis the estimates are in need of revision that fact will doubtless be made known in discussion of the paper.

Summing up this first part of the paper the following table is presented:

Approximate Estimates of Savings During Seven Months Due to Reduced Use of Artificial Light

	Reduction in total output	Saving in coal	Saving in expenditure for artificial light
Electricity (Central Stations)	3 per cent	300,000 tons	$14,000,000
Artificial gas	3 per cent	195,000 tons	5,250,000
Totals		495,000 tons	$19,250,000

PART 2

Historic Note

Benjamin Franklin is considered to be the father of daylight saving.* In 1784 Franklin[7A] stated that by rising with the sun, Parisians might save one hundred million francs annually through the reduced use of candles. He suggested that the public be compelled to practise economy in this matter. A tax of a louis per window shuttered in the morning after sunrise was to be a first step.

Every morning as soon as the sun rises let all the bells in every church be set ringing and if that is not sufficient, let cannon be fired in every street to wake the sluggards effectually and make them open their eyes to see their true interest.

Again Franklin says in his Autobiography—

In walking through the Strand and Fleet Street one morning at seven o'clock I observed there was not one shop open though it has been daylight and the sun up above three hours; the inhabitants of London choosing voluntarily to live much by candle light and sleep by sun light and yet often complain a little absurdly of the duty on candles and the high price of tallow.

In modern times William Willett was sponsor in England for a proposal to advance the clock in summer time in order to utilize daylight to better advantage. The subject in England was agitated from 1908 to 1914 without avail.[9] On May 1st, 1916, Germany as a war measure adopted the plan by advancing clocks one hour for the summer period; England, France and several other countries took like action within the next few months.

On this continent the experiment of advancing the clock had been tried in several localities with varying success.[8] It was adopted in Cleveland in the spring of 1914 by changing from central to eastern time. As Cleveland lies properly just within the western boundary of the eastern zone, this was not a very radical change. It proved successful and has been continued throughout the entire twelve months of succeeding years. In the spring of 1919, when standard time was advanced by federal law, Cleveland advanced its time another hour. This gave rise to much complaint, however, and clocks were retarded on May 11th, 1919, thereby bringing Cleveland to normal eastern time, this last adjustment being still in effect. In Detroit, which lies just within the eastern boundary of the central zone, the clocks were advanced on May 15th, 1915, bringing the City into conformity with normal eastern time both in summer and winter.

In the United States at large agitation for clock advancement in summer time became more pronounced. The National Daylight Saving Association was formed to promote the plan, and the project was furthered by reports of committees of, among others, the Boston Chamber of Commerce and the Chamber of Commerce of the United States. Finally a bill passed by both Houses of Congress was approved March, 1918, fixing standard time to govern the movement of common carriers engaged in interstate commerce and other activities under federal jurisdiction, and providing for the advancement of such standard time by one hour during the period between the last Sunday in March and the last Sunday in October. The States of New York and Pennsylvania adopted parallel legislation to govern state activities. The Federal Act remained in force for two years but that provision which called for advanced time during the summer months was repealed in August, 1919. The repeal became effective at the end of the daylight saving period in 1919.

*Perhaps the first recorded instance of daylight saving is that brought about by Joshua. The Biblical account relates several miracles by which the bloody conquest of Canaan was accomplished. In the rescue of Gibeon which was besieged by the associated kings of the Amorites, Joshua, even though aided by a hailstorm which slew more of the enemy than did his army, was unable to "mop up" before dark. So he spoke to the Lord and caused the sun and moon to stand still about a whole day and there was no day like that before it or after it.

In European countries such as England, France and Germany, after extended trial, the daylight saving plan will probably be followed during the coming summer as in the recent past. In Canada, after a trial during 1918, proposed renewal of the daylight saving bill was defeated in the Dominion Parliament in 1919. It is understood also that in Australia after a trial daylight saving has been abandoned.

Since the repeal of the Federal Daylight Saving Act in this country the subject has been agitated locally in several cities. For example, in Cincinnati advanced time has been adopted to be effective during the entire year, thus conforming to the action of Cleveland and Detroit. In New York, Hartford, Philadelphia, Pittsburgh, and other cities, provision has been made for advanced time in municipal activities during either five or seven summer months. In Chicago after consideration it has been decided to adhere to normal federal time.

After a year's experience in England a Parliamentary committee conducted an investigation of "Summer Time" (clocks advanced by one hour) and reported in favor of its continuance.[9] In the United States there has been no organized investigation of its operation.

Advantages and Disadvantages of Daylight Saving

The advantages which in advance of adoption the measure was said to offer were principally: increased opportunities for outdoor recreation, reduced consumption of fuel, saving in expenditure for artificial light and promotion of gardening. The disadvantages which were anticipated included confusion in railway schedules, confusion as between astronomical and legal time, and possible interference with children's sleep. The author has reviewed the literature of the subject and has instituted inquiries with a view to collecting information on these and other advantages and disadvantages. In consequence there is at his disposal a great mass of opinion but very little definite information. From these the following statement of advantages and disadvantages has been prepared.

Outdoor Recreation. To those engaged in sedentary pursuits and who are in a position to devote spare time to outdoor recreation, daylight saving undoubtedly has been a boon. Public playgrounds and parks of our cities have borne witness to the stimulation which daylight saving has given to outdoor sport. Tennis and golf (Fig. 9) have become more popular, conferring benefit upon many who probably without the additional hour in the afternoon would not have found it practicable on weekdays to avail themselves of these forms of exercise. Opportunities for pleasure automobiling on weekdays have been multiplied. Amateur baseball, and in general unorganized forms of sports, have been promoted. Business men who maintain their own homes have found an added opportunity on weekdays to carry out in daylight the numerous maintenance operations which fall to their lot. In general, the effect of daylight saving has probably been to promote outdoor living with greater enjoyment of daylight by all members of families. Those who could and did avail themselves of the added opportunity have undoubtedly derived physical benefit which has reacted mentally and increased their value to the sedentary occupations in which they are engaged during business hours. Moreover there was probably a wholesome tendency as time passed for more and more people to avail themselves of such added opportunities.

Fig. 9 Photo by Underwood and Underwood

Coal Saving. In Part 1 of this paper it is estimated that the reduction per annum in consumption of coal for lighting is of the order of 495,000 tons. This includes electricity for lighting supplied by central stations and artificial gas.

Saving in Expenditure for Artificial Light. The saving in expenditure for electricity and artificial gas is estimated in Part 1 to be of the order of $19,250,000.

Gardening. The amateur gardening movement was more or less coincident with the large increase in the cost of living which began in 1915. Novelty, recreation and economic advantage all played their part. To this after we entered the war there was added patriotic aspiration.[10] The added hour between the close of business and dark probably assisted amateur gardeners (Fig. 10).[11] It is difficult to determine with what part of the increase in such garden produce it should be credited.

Private gardening was carried on to an increasing extent in suburbs and small towns and in the country before the advent of daylight saving. There is no indication that the daylight saving measure either added to or detracted from private gardening.

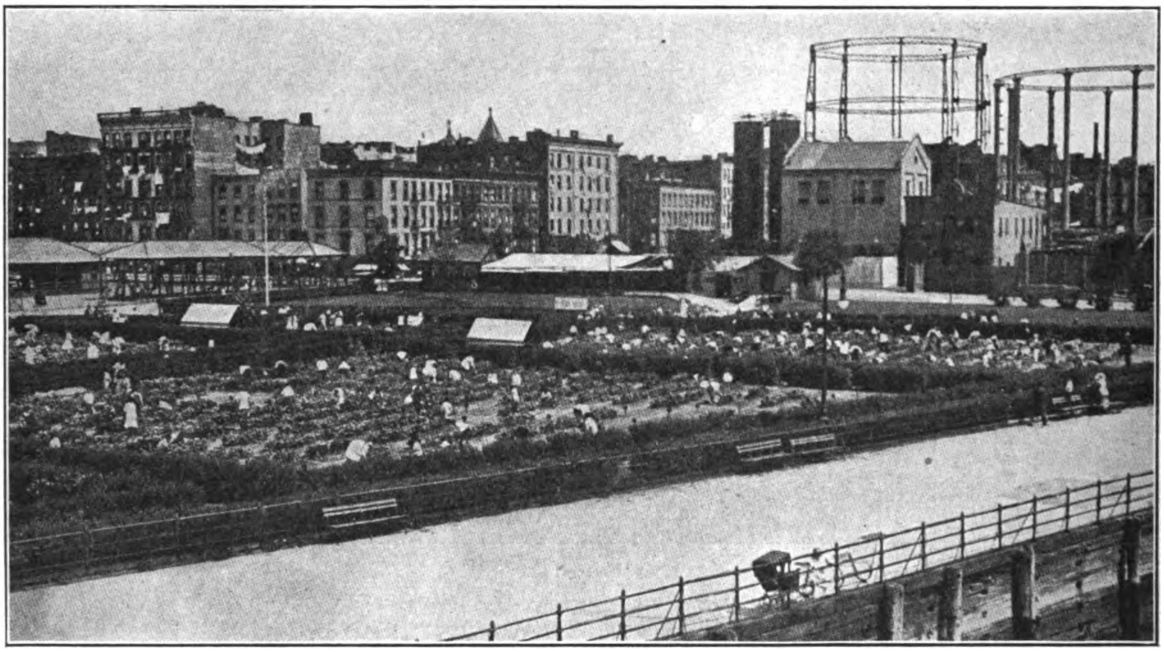

FIG. 10 From "The War Garden Victorious"—Lippincott

Gardening by those who produce a surplus for sale has been impeded by the Daylight Saving Act. Truck gardeners in general have opposed the measure. Vegetable and market-growers' associations in several parts of the country have demanded its repeal. The general reasons given are that advanced time compels gardeners to begin their activity too early for agricultural purposes, but necessarily early in order to maintain contact with the market. These people have to go to bed in daylight or sacrifice sleep.

Upon the whole the evidence appears to be that the disadvantages to professional gardeners of daylight saving have outweighed the advantages to amateur gardeners.

Health. There appears to have been no organized study of the effect of daylight saving upon health.[12] The Federal Public Health Service[13] has no definite information on the subject. The American Medical Association while calling in June, 1919 for a continuance of daylight saving[14], appears to have based its action upon the belief that increased opportunity for outdoor recreation has probably added materially to health and vigor.[15] There is a general view among hygienists that facilities for recreation during daylight are advantageous to those who can and do avail themselves of them.[16] Although there is lack of definite information showing benefit to health, yet it is probable that real improvement has accrued to certain classes of urban and suburban dwellers.

There seems to be practically a consensus that advancement of the clocks in summer brings bedtime for small children well into daylight and interferes with their sleep. Thus children either sit up later or after retiring remain awake later by the clock than formerly. Just how much weight is to be given to this disadvantage is for hygienists to determine.

Those who live in city tenements as a rule have neither time nor money for the forms of outdoor recreation which are promoted by daylight saving. With the day's work finished their desire is more for rest than for recreation. Their homes lack many comforts and are often ill ventilated and congested. In summer it is a problem with these people to get sufficient restful sleep. The arrival of bedtime finds bedrooms uncomfortably hot and stifling. Recourse is bad to sleeping on fire-escapes, and in extremely hot weather to sleeping in parks, and for those who can do so, on beaches.(Fig. 11). To these people daylight saving is disadvantageous during the summer months. They must choose between retiring to their uncomfortable rooms one hour earlier or losing sleep. On the other hand they must arise one hour earlier in the morning at a time when the most refreshing sleep is

to be had. It is said to be the judgment of nurses and visitors who are constantly going in and out of tenement homes that this is an appreciable factor.

A conclusion as to the effect upon health should be reached after weighing on the one hand additional outdoor recreation on the part of those who can avail themselves of the added opportunities, and on the other hand interference with the sleep of children, with the sleep of all who must retire before dark in order to rise early, and with the sleep of all in this climate in hot weather.

Farmers. The most serious complaints concerning disadvantages of daylight saving have come from farmers. To this class is to be attributed most of the influence which led to the repeal of daylight saving. One cannot peruse the agricultural journals and the reports of Congressional hearings on daylight saving without being impressed with the practical unanimity and earnestness of the farmers' opposition.[17] The

Fig. 11 Photo by Brown Brothers

crux of the difficulty is that much of the farmers' work must be regulated by the sun, compelling him to work under normal time, while certain activities as a practical matter have to be adjusted to conform to advanced summer time. The conflict between the two is intolerable. In order to connect with milk trains the schedules of which cannot well be altered because they must serve those who abide by advanced time, it is necessary for the farmer's day to begin one hour earlier than usual. In order that children may attend to chores and get off in time for school, there is the same requirement for earlier rising. This earlier rising in itself is objectionable. The early morning work completed, it is necessary to wait for certain cultivating and harvesting purposes until the dew is evaporated. In considerable part this hiatus means waste. Generally speaking, the farmers who produce surplus food products employ labor. Hired labor is unwilling to work one hour later than do those not engaged in agricultural work. Quitting at the usual clock time, there is a loss of the hired man's time. The farmer himself on occasions when he desires to go to the neighboring town for business, recreational or social purposes must quit one hour earlier, sun time. The curtailment of farming activity thus occasioned is at the time of day which is best for planting and harvesting purposes.

Farmers refer to the measure as "Daylight Wasting."[18] It is obviously difficult to arrive at a definite statement of resultant loss, but some estimates will prove suggestive. It is estimated that the efficiency of farm help is reduced 15 per cent.[19] The loss to farmers involved in daylight saving is estimated to run 18 per cent as the average of a number of farms.[20] Daylight saving is estimated to have added 15 to 20 per cent to the cost of production on farms.[20] United States Senator Capper of Kansas estimates that daylight saving occasions waste aggregating $1,000,000,000 a year.[21] While it is impossible to make any definite statements, yet it is evident that the disadvantages to farmers are large. As a result, agricultural organizations and journals are very generally opposed to daylight saving.[17]

Dairying. In dairy farming the objections to daylight saving are quite as strong as in agricultural work. To accommodate advanced time cows must be brought in for milking in the morning one hour earlier than usual, and sometimes before daylight. Again they must be brought in in the hottest part of the afternoon. Aside from the inconvenience and hardship which this works upon the dairy farmer, it is stated that there is a very noticeable decrease in the milk yield, one estimate placing the quantity as high as two quarts per cow per day.[22] Under conditions with which the author is personally acquainted on a large dairy farm, a somewhat smaller but quite noticeable reduction has been experienced. It is understood that there are about 300,000 cows in New York State alone. It will readily be seen that the loss in milk will aggregate several millions of dollars.

Miners. Next to farmers, miners have probably protested against daylight saving more than any other class of people. This is especially true of those in the Middle West. It is necessary for their wives to rise before daylight to prepare breakfast and pail luncheon, and for the miners to leave home unduly early (sun time) in the morning. At the other end of the day this means retiring while it is still light in the heat of the evening.[23]

American Federation of Labor. Delegates to a convention of the American Federation of Labor expressed themselves as in favor of the daylight saving project when the plan was proposed during the war. Officers of the Federation have continued to favor the plan. At the convention of the Federation in June, 1919, however, the delegates voted in disapproval of daylight saving.

Financial Relations with Europe. One point claimed for advanced summer time was that it would bring

exchanges in this country into better contact with those of Europe, due to overlapping of hours of active trading. The author is advised that no advantage has been realized, however, because arbitrage transactions by cable have been out of the question since the outbreak of the Great War.

Accidents. Another claim advanced for daylight saving was that there would be fewer accidents in industrial districts under advanced time. No information is available to show that such has been the case. Inquiry has brought advice that it would not appear that there has been any appreciable benefit which could be traced to the advent of daylight saving.[24]

Summary of Advantages and Disadvantages. Examined in the light of such information as is available, daylight saving is seen to have promoted outdoor recreation on the part of those who were in a position to avail themselves of the opportunity afforded. It has saved fuel although the amount of saving is less than has been claimed. It has reduced expenditure by the public for artificial light but to an amount less than has been stated.

There is nothing to show that the net effect upon the health of the people as a whole has been either beneficial or harmful. Its effect upon financial relations with Europe has not been felt. No effect upon accident rates has been observed.

Its effect upon gardening and garden produce has probably been more harmful than beneficial. It has interfered with the sleep of small children, and has probably caused discomfort to urban poor. Farmers have been inconvenienced, and the efficiency of farm labor has been decreased. Estimates indicate that agricultural losses of a large order have been occasioned. Dairying has been interfered with, and milk yield of cows has been diminished slightly. Miners have been inconvenienced.

Author's Deductions and Opinions*

During the agitation leading up to adoption of the Daylight Saving Act in the spring of 1918, the writer paid but little attention to the subject. He first became interested as a result of being called upon to make a presentation on the subject before the war meeting of the National Electric Light Association in 1918. Being but little affected one way or the other by advancement of the clock he undertook an examination of the subject fairly free from prejudice, and has followed the development of the discussion and has talked with various classes of people and has observed the workings of advanced summer time with increasing interest ever since.

Why do we Distribute the Hours of the Day as at Present? A natural question growing out of the proposal to advance summer time was early recognized; namely, why have we adopted existing hours for work, play and sleep? There has been no legislation necessitating the adoption of particular hours. There was not even federal legislation fixing standard time until the passage of the Calder Daylight Saving Act in 1918. Yet in our own time and in earlier times it has been the practise to postpone retiring considerably beyond the end of daylight and to remain in bed considerably beyond sunrise in the summer time. Even in the days of tallow candles, as evidenced by the strictures of Franklin excerpted in the Historical Note of this paper, it was customary to postpone retiring, thus incurring considerable expense for artificial light of a most inferior quality.

In searching for an explanation of this fact, the author arrived at the conclusion that our practise in distributing the 24 hours is the result of a compromise between considerations of light and temperature. It would appear that time of retiring and rising and choice of hours for work and for recreation may be varied considerably in the spring and in the autumn without incurring any disadvantage growing out of temperature extremes. In winter and in summer, however, temperature extremes impose limitations upon living conditions which cannot be ignored. In winter time the problem is to keep warm. In earlier habitations and in dwellings of the poor today, this problem is especially difficult. There is no place where it is quite so easy to keep warm as in bed. When the heating problem is difficult therefore, the natural thing to do is to spend in bed the hours of lowest temperature. In summer the problem of securing restful sleep is one of keeping cool. Considering the way in which indoor temperatures lag behind outdoor temperatures in summer, the choice of hours for most comfortable sleep, if guided alone by the temperature consideration, would be even later than in the winter. Customs tend to become fixed, however, and again a compromise between temperature conditions and light conditions appears to have been reached in the choice of hours for sleep.

Fig. 12 gives for three representative months of the year under New York conditions, fluctuations in outdoor light and temperature. If one were to choose the eight-hour period of the 24 in which outdoor temperature upon the whole is lowest, he would probably select the period 1 a.m. to 9 p.m. The actual period for sleep taken in the diagram as 10:30 p.m. to 6:30 a.m. seems to be a compromise between a choice of the lowest temperature period and a choice of the period of darkness for sleep purposes. It appears to the author that the allocation of time to sleep, work and play has been dictated in part by a choice of the most suitable hours for sleep as well as by choice of the most suitable hours for work. Therefore the arbitrary advancement of clocks by

*The author's thanks are extended to those who have given him the benefit of suggestions and criticisms and to whom he is greatly indebted in connection with the preparation of this paper.

one hour in the summer time upsets the deliberate custom of a whole people, which custom has been arrived at through experience in which the only consideration has been the greatest comfort and advantage of the greatest number of people. Left to choice in summer time the majority of people would probably prefer to go to bed later and rise later in the morning rather than to go to bed and rise at an earlier hour. Evidence of this is to be seen on every hand in the practise of people on Sundays. Whether it is due to indolence or an unconscious striving for maximum comfort is a question the answer to which will not controvert the proposition that the great mass of the people in summer time would prefer to rise and retire later instead of earlier.

Class Thinking. Most persons whose opinion the author has asked on this subject, and probably most persons in this audience, express themselves as in favor of daylight saving. These are people in general whose hours of business are from 9 a.m. to 5 p.m., who have some opportunity for devoting to outdoor recreation leisure time after business hours. This likewise is the class from which advocates of daylight saving come. The subject appears to have received but little comprehensive consideration along national lines. Those favoring and those disfavoring the plan appear to have consulted their own experience and predilection and to have devoted little attention to the other side of the case. The literature as put forward by advocates of daylight saving fails to recognize any disadvantage as accruing to the plan. The benefits to the so-called "laboring class" are stated not by members of that class, but by employers or office workers. The real benefits accruing to a large class of urban dwellers are deprecated by agricultural opponents of the plan, as illustrated by the slogan "Daylight saving means an hour saved for play in the city; it means an hour lost for work in the country." And the very real disadvantages which the measure occasions farmers are disposed of by our metropolitan press in a manner illustrated by the statement that "The farmer seems to have been convinced by some sleight of hand argument."[25]

It is significant to array classes according to their attitude toward daylight daving. It looks something like this—

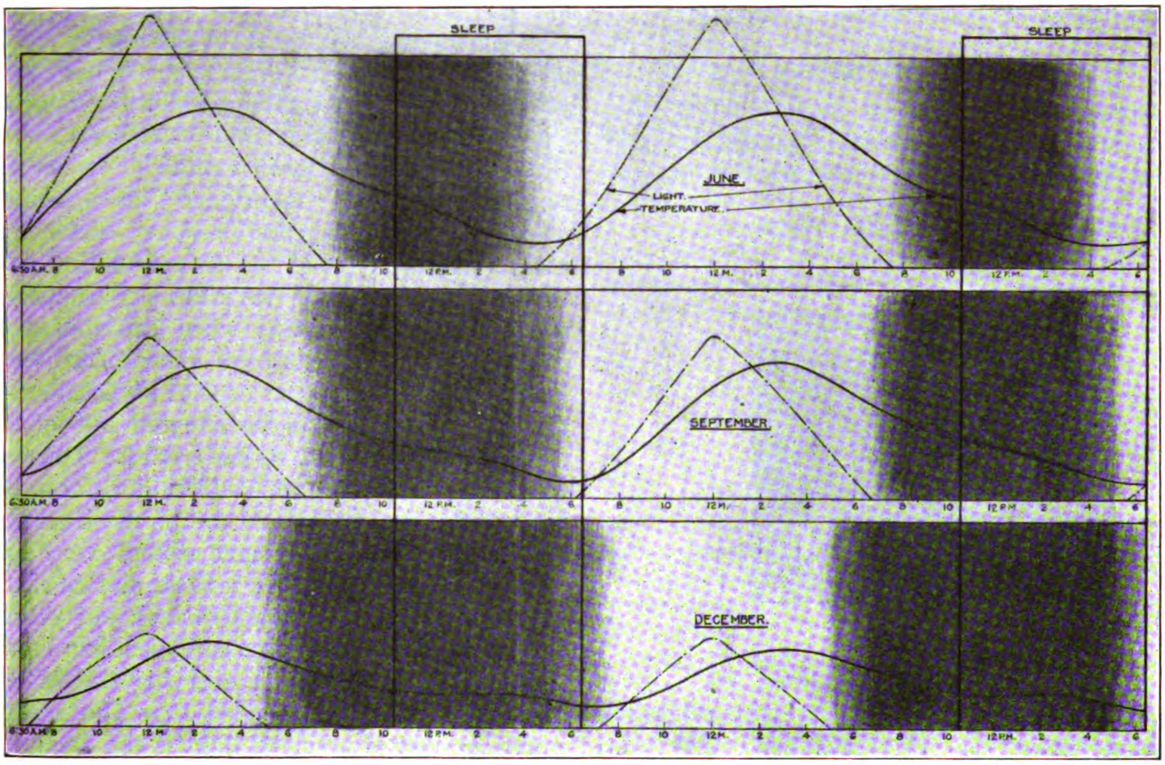

Fig. 12

Favoring	Opposed	Indifferent or Inarticulate
Well-to-do urban and suburban dwellers	Farmers Dairymen	
Officials of the American Federation of Labor	Majority of delegates to convention of American Federation of Labor	Less well-to-do and poor city dwellers
War Garden Commissions	Truck gardeners	
American Medical Association	Miners	

While the foregoing doubtless falls short of full accuracy and completeness, yet it conveys a fairly good idea of the known views on this subject. In the author's judgment there can be little hesitancy in reaching a conclusion after weighing the advantages

and disadvantages. The success, convenience and economy of the producers of food and fuel are of much greater moment to this country than is the added opportunity for outdoor recreation by the class of people which by and large is in a position to secure its own opportunities for recreation.

An unweighted count of urban versus rural populations falls far short of affording a right indication as to the advantages or disadvantages to the country. The urban population is by no means a unit in deriving benefit. Of that part of the urban population which does benefit it is to be said that their convenience or pleasure is not to be weighed on equal terms with a reduction in efficiency in the conduct of an industry which is fundamental to the country's welfare.

Economic Results

Coal Saving. It is estimated in this paper that the saving in coal accomplished through daylight saving is of the order of 495,000 tons per annum. In

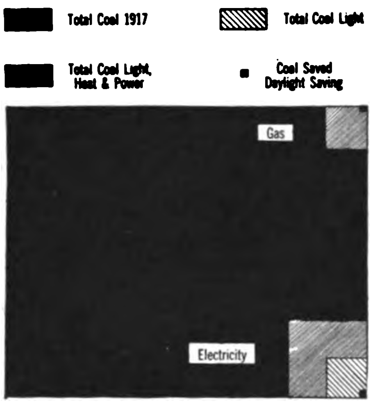

Fig. 13

order to consider this quantity in its proper relation to the coal problem, Fig. 13 is included. The total area of the large rectangle represents the total coal consumption of the country for 1917; the small cross-hatched rectangle in the lower right corner represents the coal estimated to have been consumed in electric lighting. The small black rectangle in the field of this cross-hatched area represents the coal estimated to have been saved in 1918 or 1919 as a result of the reduced use of electric light under daylight saving.

The small cross-hatched area in the upper right-hand corner of the rectangle represents the net coal consumption estimated to have been used by the gas industry in 1917. The small black rectangle in the cross-hatched field represents the saving estimated to have been effected in 1918 through daylight saving. It will thus be seen that the aggregate reduction in the consumption of coal in advanced summer time, while large and important, yet relatively is but a fraction of one per cent of the coal consumption of the country. It may be compared with the figure of 1,250,000 tons usually stated to represent the saving which is effected.[26] The advantage of the Daylight Saving Act as a fuel conservation measure is therefore less than it has been stated to be.

Saving in Expenditure for Artificial Light. Advocates of daylight saving have claimed a one-quarter reduction in cost of artificial light. It would appear probable that their views have been based upon reduction in hours of lighting in the evening which, as shown in Fig. 8, are of the order of 29 per cent. The same diagram shows that in reality the reduction in cost of electric light is only one-quarter of that which might be indicated by this line of reasoning. Estimates of the saving in expenditure of the public for artificial light have ranged from $40,000,000[27] per annum to $100,000,000[8] per annum. In this paper it is shown that the total for electricity and artificial gas is of the order of $19,250,000. This comprehends probably most of the saving which is effected, so that the benefits to the public under this head would appear to be less than has been claimed. If we ignore the reasons previously mentioned for qualifying this statement of saving and assume that the public receives the full benefit of this reduction in expenditure for artificial light, we still have to consider what such a reduction means when distributed over the country. The public's total expenditure for artificial light is only 1 to 1½ per cent of its total expenditure; any saving which can be effected out of this small expenditure is bound to be trivial. Tobacco,[28] soda fountain products[29] and confectionery absorb a larger part of the expenditure of the public than does artificial light. One would not esteem very highly the saving of the expenditure for one or two cigars or one or two ice cream sodas per person per year, yet this is all that is saved in reduced expenditure for artificial light. Therefore without decrying the value of small savings, it may be asserted that the saving to the public in cost of artificial light is too small to be considered as an important factor in weighing the advantages of daylight saving.

On the other hand, when considering economic results, it is necessary to take into account losses suffered by the public as well as saving effected. Some idea of these is obtained by considering interference with agriculture, dairying, and truck gardening. Obviously the estimates of agricultural losses are rough approximations and are probably of a less reliable order than are the estimates in this paper of the effect upon use of artificial light. There appears to be no doubt, however, that the agricultural losses are many times greater than the savings in artificial lighting and it is therefore justifiable to contrast the two estimates in order to emphasize this fact. Thus:

Gain to Public

Estimated savings in electric light	$14,000,000
Estimated savings in gas light	5,250,000
Estimated savings in other forms of artificial light	Probably negligible

Losses to Public

Agricultural losses estimated at	$1,000,000,000
Dairying losses	?
Truck farming losses	?

By those so situated as to be familiar with the facts, it is asserted that daylight saving has made agricultural life less attractive; it has interfered with the "back to the farm" movement; it has probably contributed somewhat toward increasing the cost of living.[30] The economic losses thus involved run so high that the saving in artificial light by comparison sinks into insignificance.

Only one side of the economic phase of daylight saving is presented by advocates of daylight saving. The agricultural disadvantages apparently failed to attract attention when the project was first considered. They proved so serious, however, as to occasion overwhelming adverse sentiment among the members of the House and Senate which led to repeal of the Federal Daylight Saving Act.

Undesirability of Local Action. Whatever the advantages or disadvantages of advanced summer time as a national measure, it would appear that its adoption in particular localities is subject to additional disadvantage. Where such action has been taken the citizens, in the adjustment of industry and of their daily movements, must choose between federal time which will be followed by post office, custom house, railroads, national banks, United States courts, etc., and municipal time which is one hour different and which will be followed by municipal courts, police and fire departments, municipal departments, etc. There is no compulsion upon the public to be guided by either. The attendant confusion, however, is bound to be serious.

Conclusion

It is a fallacy to think that in order for one class to benefit, change must be imposed upon the whole people. It is important to "think nationally." To secure the greatest advantage to the whole people should be the aim.

The very obvious solution of the problem appears to lie in diversification of hours of industry. There are certain classes of people in the cities and suburbs who are in a position to derive benefit from advanced summer time. Without molesting the customs of an entire nation let them undertake an educational propaganda in favor of early rising and early retiring in summer time, together with advancement of the beginning of business hours from say 9 to 8 a.m. It will probably follow that where the advantages of such altered practise seem sufficient, business hours in certain kinds of work will be advanced with consequent diversification of the traction peak, bringing greater comfort to those who must travel in the rush hour. This will avoid local misadjustment of clocks with the attendant confusion which will arise from difference between federal and local time. Education leading to intelligent selection of hours for work, sleep and play is much to be preferred to arbitrary legislation compelling official misrepresentation of time which has the effect needlessly of imposing the will of one class of the population upon another class.

A New Form of Vibration Galvanometer

BY P. G. AGNEW

Secretary, American Engineering Standards Committee

Vibration galvanometers are very useful in null measurements, but have not been much used in industrial laboratories on account of their being sensitive to external vibrations and requiring delicate adjustments. The present instrument, which has a sensitivity higher than other forms of the moving-iron type, but less than that of the most sensitive forms of the moving-coil type, has the advantages of sturdiness, quick responsiveness, and freedom from the effects of external vibration. It consists essentially of a fine steel wire, mounted on one pole of a permanent magnet, and so arranged that the free end of the wire may vibrate between the poles of an electromagnet through which the current to be detected passes.

THE vibration galvanometer is a very useful instrument in alternating-current measurements where null methods can be used as, for example, in an almost endless variety of bridge measurements, in various applications of the alternating-current potentiometer, and in testing instrument transformers. As in the case of direct-current galvanometers, there are two general types of vibration galvanometers, the movving-coil type and the moving-iron type. In each type the moving element is mechanically tuned so that its natural period is the same as that of the alternating electromagnetic forces produced by the current to be detected, thus using the principle of resonance to produce a relatively large motion for a very small current.[1]

The reading is usually made by observing the image of an electric lamp filament reflected in a very small mirror attached to the moving system, by means of a telescope, or by a projection upon a screen. When current passes through the instrument the vibration of the moving element causes the image of the filament to appear to broaden out into a band.

It is evident that a vibration galvanometer of either type is simply a specialized form of synchronous motor, the whole mechanical output of which is used in overcoming air friction and elastic hysteresis.

To be presented at the Midwinter Convention, New York, February 20, 1920.

1. For a general discussion of vibration galvanometers, see: Laws' Electrical Measurements, 1917, p. 434; F. Wenner, TRANS. Am. Inst. Elec. Engineers, 31, p. 1243; F. Wenner, *Bull. Bureau of Standards*, 6, p. 347, 1910; A. Campbell, *Proc. Physical Society of London*, 26, p. 120, 1914.

The vibration galvanometer has been used but little in industrial laboratories, its principal use being in physical laboratories, and principally in precision work. The chief reasons for this limited use are that it is easily disturbed by external mechanical vibrations, and that delicate adjustments are necessary. In the present form of instrument these difficulties are greatly reduced. It is not, however, as sensitive as some forms of the moving-coil type.

Principle of Operation. The present instrument is of the moving-iron type. It consists essentially of a fine steel wire, mounted on one pole of a permanent magnet, and so arranged that the free end of the wire may vibrate between the poles of an electromagnet through which the current to be detected passes. If an unmagnetized steel wire, W, is held near the pole of an electromagnet, as in Fig. 1, the end of the wire will be pulled toward the pole of the electromagnet during each half wave of the current flowing in the winding of the electromagnet. That is, the wire will vibrate with twice the frequency of the current. If the wire be magnetized by mounting it on the pole of a permanent magnet, the free end of the wire will be alternately attracted and repelled by the alternating flux of the electromagnet. That is, the wire will vibrate with the same frequency as that of the current. But what is of more importance, the alternating mechanical pull will be very much greater than with an unpolarized wire, since the total flux from the wire is much greater.

The permanent magnet plays the same role in increasing the motion of the wire that the permanent magnet in a telephone receiver does in increasing the

motion of the diaphragm. The total pull varies as B^2, and the change in the pull varies as the change in B^2 resulting from the alternating current. Hence if a given small alternating current produces a change in flux, ΔB, the alternating mechanical pull is proportional to $B \Delta B$, instead of to $\overline{\Delta B^2}$, as it would be if the wire were not polarized by the permanent magnet.

Fig. 2 shows one of the first arrangements experimented with. A small electromagnet is mounted on the inside pole face of the permanent magnet, and the fine wire vibrator on the opposite pole face. The operation is readily seen. During one half-cycle the flux from the pole tip A is slightly strengthened, and that through B is weakened. Hence the vibrator moves toward A. During the next half-cycle the conditions are reversed and the vibrator moves toward B, and so on.

Considering the arrangement as a motor, it is easy to see how the back electromotive force is generated. If the vibrator is moved back and forth by mechanical means, magnetic lines of force from the end of the vibrator move back and forth between A and B, alternately increasing and decreasing the flux in each, and thus generating an alternating electromotive force in the winding.

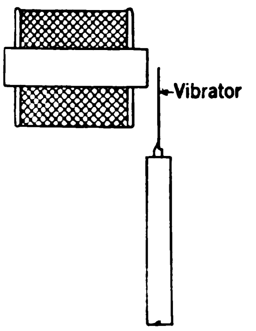

FIG. 1

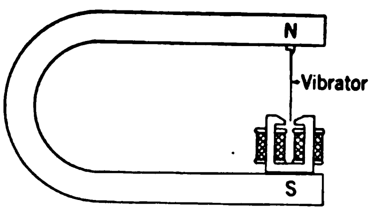

FIG. 2

The vibrator, which is, of course, mechanically tuned so that its period is the same as that of the current to be detected, is observed by a telescope mounted perpendicular to the plane of the paper and focused on the end of the vibrator. In this way a much smaller motion can be detected than is possible with the unaided eye.

During a set of experiments undertaken in order to determine optima of conditions, such as size and shape of electromagnet, shape of pole tips, length of gap, and distance between end of vibrator and pole tips, an interesting observation was made. As a limiting case, the air gap of the electromagnet was reduced to zero by using a closed core as shown in Fig. 3. Even under this condition the device was nearly a tenth as sensitive as with the best arrangement that could be obtained with the same core after it had been sawed so as to form an adjustable gap.

Arrangement for Greatest Sensitivity. Of the many arrangements of parts that have been tried, that which gives the greatest sensitiveness and general convenience of working is shown in Fig. 4.

The electromagnet is placed outside the gap of the permanent magnet, but in a position in which an appreciable amount of flux from the latter passes through the cores of the former. It is to be noted that in principle the arrangement is identical with the earlier one described above, the most important difference in the details of the arrangement being the weaker field to which the core is subjected. The two principal advantages of putting the electromagnet outside are: first, other things being equal, the instrument will

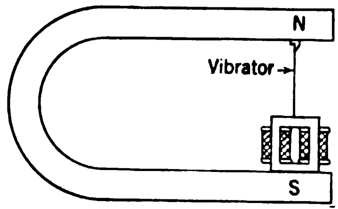

FIG. 3

be most sensitive when the core is working at the point of maximum differential permeability, and the point of maximum differential permeability occurs at very low values of B, (ideally, at $B = O$); second, with low frequency vibrators, which must be of very small diameter, the effect of the strong magnetic field upon the frequency of the vibrator introduces practical difficulties in tuning, since the magnetic forces combine with the elastic force to change the total restoring force, thus changing the frequency. The relative positions of the permanent magnet and the electromagnet were varied systematically, but, as would be expected, the one shown gives the best results.

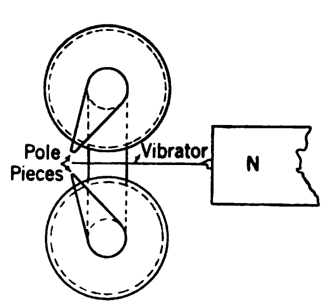

FIG. 4

A high differential permeability is necessary, as just mentioned, for sensitiveness. This means a high initial permeability in the core. Decidedly the best results have been obtained with cores made of good sheet silicon transformer steel. Results seemed to indicate that the sensitiveness varies as the square of the initial permeability instead of as the first power, as was expected, but sufficiently accurate data was not obtained to make certain on this point.

If it is attempted to increase the sensitiveness by bringing the end of the vibrator close to the pole tips, a condition of instability is reached, the vibrator being

pulled over to one or the other of the pole tips. Other practical difficulties arise, such as changes in the tuning of the vibrator. In general, the shorter the gap, the closer can the end of the vibrator be placed to the pole tips without such difficulties being encountered. Considerable changes may be made in length of gap, shape of pole tips, etc., without greatly affecting the maximum working sensitiveness attainable by the various adjustments.

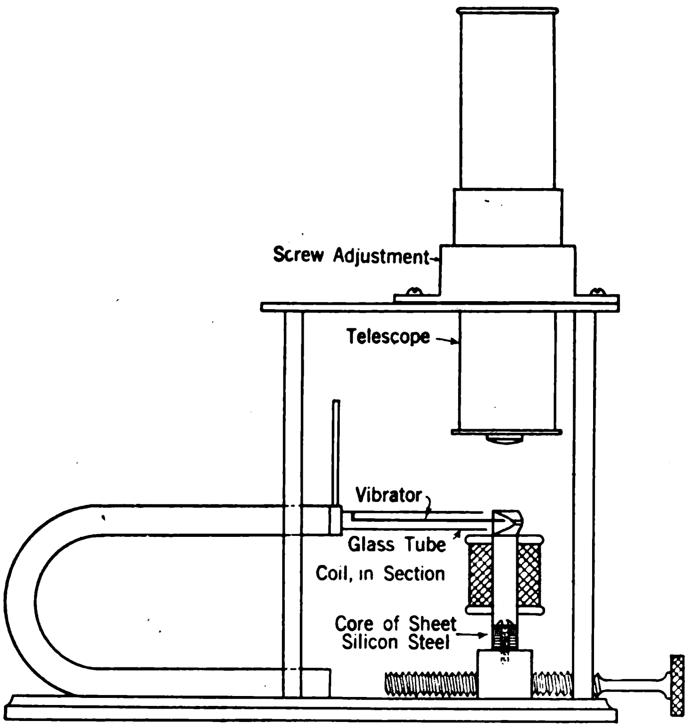

Fig. 5

Generally satisfactory results are obtained with the pole tips brought down in the form of truncated pyramids, the faces being about 2 by 0.5 mm., the short edge being parallel with the plane of vibration of the vibrator, a gap of about 1.5 mm., and the end of the vibrator about 1.5 mm. from the pole tips. An improvement by a factor of 1.5 to 2 may be obtained by setting the pole tips at an angle, as the field is intensified by such an arrangement, (See Fig. 5).

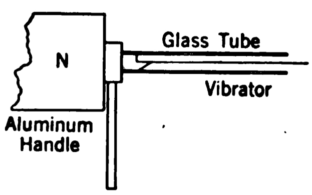

Fig. 6

The Vibrator. The vibrator is mounted on a small base of soft steel, as shown in Fig. 6, and is held in place magnetically, by merely placing the base on the face of the magnet. For convenience in changing vibrators for different frequencies, an aluminum wire is inserted in the base as a handle. For a 60-cycle vibrator a 0.1-mm. wire is convenient, and with this diameter a length of about 33 mm. is required. A 0.04-mm. wire of the same length has a frequency of about 25 cycles. For soft steel wires, the following formula is sufficiently accurate for design purposes:

$$\text{Frequency} = 65{,}000\,\frac{\text{diameter}}{(\text{length})^2}$$

where the dimensions are in centimeters.[2]
For piano wire the constant is higher, about 70,000.

At first it was hoped that such a vibrator might be permanent enough in its frequency to serve the purpose of a frequency meter as well as that of a galvanometer, but it is not feasible, since the actual resonance frequency depends to a small extent upon the position of the vibrator in the magnetic field. Advantage may be taken of this fact, however, to provide a fine adjustment for tuning the vibrator to the exact frequency desired. If an auxiliary small magnet, or better, a pair of such magnets, is placed near the end of the vibrator, the frequency may be changed several per cent, by changing the position of the auxiliary magnet. While it does not readily provide as large a range of adjustment, a more convenient method is to move an iron rod toward or away from one pole of the permanent magnet by a screw motion, as shown in Fig. 4.

If the vibrator is polished, and illuminated by a horizontal beam of light, a sharp line of light may be obtained in the microscope, very similar in appearance to the image of an incandescent filament of moderate brilliancy when viewed in a telescope. Satisfactory readings may also be made by viewing the wire in the ordinary way. In comparing sensitiveness it is convenient to use a vibration just sufficient to make the vibrator appear of double diameter.

It is well to keep the vibrator covered with a very thin film of oil to prevent corrosion. The effect of such a film on the frequency is too small to be at all inconvenient. For many purposes it is convenient to shield the vibrator with a glass tube, as in Fig. 6.

Performance. With a magnifying power of 50 to 100, which has been found satisfactory under working conditions, a motion of the vibrator of five microns is easily visible. With a one-ohm winding an electromotive force of three microvolts can be detected. The construction is such that high resistance coils may easily be wound for high current sensitivity. With a 270-ohm winding the sensitivity is such that a current of 0.05 microampere can readily be detected.

---

2. This formula is in the form given by Rayleigh, (Theory of Sound, Vol. 1, art. 171), for the design of the rectangular prong of a tuning fork,

$$N = 84{,}590\ t/l^2$$

where N is the frequency, t the thickness, and l the length.

The chief advantages of the instrument are its sturdiness, the ease of adjustment, its quick responsiveness, and its freedom from the effects of external vibration. In the last characteristic the instrument is an order of magnitude better than any other form of vibration galvanometer with which the author is familiar. Both the freedom from external vibration and the quick responsiveness are due to the relatively large damping by air friction, and the extremely small mass of the moving element. Although the vibration galvanometer depends upon the principle of resonance, an appreciable amount of damping is necessary to give a reasonably quick response to changes in circuit conditions, and the smaller the mass of the moving element, the smaller the amount of energy necessary for a given amplitude, and the more quickly will the requisite amount of energy be supplied from the circuit.

The "resonance range" is about one per cent. That is to say, if the frequency of the current is one per cent above or below the frequency of resonance, the amplitude of vibration will be half as great as at resonance.

The efficiency of the present instrument as a motor is very low, the back electromotive force being only a few per cent of the applied electromotive force. If it should be found possible to increase the electrical efficiency of the device, as a motor, to 50 per cent, the sensitivity would be increased in like ratio, and the instrument would be able to do the work of the most sensitive form of the moving-coil type. Wenner has shown that it is possible to develop an electrical efficiency of over 97 per cent in a vibration galvanometer of the moving-coil type.[3]

The instrument, in various stages of development, has been used in routine testing at the Bureau of Standards for more than three years. While many improvements have been made in detail, a much-to-be-desired radical increase in electrical efficiency has not been accomplished. One possibility is the use of a hardened steel vibrator, permanently magnetized, but a preliminary substitute experiment, in which a soft iron vibrator was surrounded by a magnetizing coil, did not show encouraging results. No attempt has been made to put the vibrator in a vacuum so as to reduce the air friction. It would be necessary to use a fairly high vacuum as the resistance of the air is nearly independent of the pressure down to a pressure of about one mm. of mercury. The sharpness of tuning necessary would increase as the sensitiveness increased, as would also the response to external mechanical disturbances, especially disturbances synchronous with the current. A very promising line of attack which has not been tried is the use of a vibrator made of vacuum process iron, to secure, if possible, a much higher flux in the vibrator.

I am indebted to Mr. J. B. Dempsey for a large part of the experimental work, and for valuable suggestions.

ENGINEERING AS PROSPERITY INSURANCE

Professor Ely, the economist, has boiled down his discussion of the principles of conservation into half a dozen words that can serve as a rule of action: "*civilization means regard for the future.*" So when I suggest that engineering is prosperity insurance, my choice of words has not been prompted by the professional character of the audience I face but rather by my idea of what the world needs most.

Fortunately I do not have to define my terms; I have only to set forth the way in which the relation between engineering and prosperity impresses me as paralleling in thought the Ely equation—that civilization means regard for the future. Engineering deals in futures; the engineer ever keeps the factor of safety in mind as he works; he is an insurance agent of the first magnitude, even if he does not talk like one.

What we seek for our country, then, is welfare rather than wealth—happiness in fact rather than greatness in name. The members of this Engineers' Club do not need to be more than reminded that "the pursuit of Happiness" was one of the great self-evident truths set forth in that Declaration of Independence, which our fathers assembled here at Philadelphia gave to the world. Nor are we likely ever to overstress the "general welfare" clause of the Constitution as a guiding purpose in our work, whether we serve the public as engineers in private or corporate employ or as engineers on some public pay roll. To strive for well-distributed happiness and to promote the general welfare are aims that belong in the code of the engineer who raises his life work to the level of a contribution to the future.

My conviction is that the future of our nation will be largely what engineers make it, and the surplus that can be paid to other generations of Americans will depend upon what you engineers of today write into that endowment policy, which is to be broad enough to cover Philadelphia, Pennsylvania, and America.

The nation, like the family, can safeguard its future by thrift. We admire Colonial architecture and reproduce it as the fit setting of the modern home; some of us have time and money enough to collect handsome specimens of the stately furniture of Colonial days; all of us may well copy the early American rule of "work and save." Not only did many conspicuous family fortunes have their origin in those early habits of thrift, but our national wealth has accumulated in the same way; as a nation we have produced more than we have consumed. We need now to think in terms of production, simply because without production we cannot consume.

From an address by George Otis Smith, Director, U. S. Geological Survey, before Engineers' Club of Philadelphia, January 20, 1920.

A Method for Separating No-Load Losses in Electrical Machinery

BY CARL J. FECHHEIMER

Designing Engineer, Westinghouse Electric and Mfg. Co.

The method proposed makes use of idle operation of the machine as a motor, the voltage being varied, and speed kept constant. After deducting the armature $I^2 R$ losses from the watts input, the remaining watts are plotted against the voltage. A formula is derived based upon the assumption that the watts are equal to constant windage and friction loss plus core loss which latter varies as a constant power of the voltage. In applying the method, tangents to the curve are drawn at two points, and from the slopes of these tangents, the voltages and watts at these points, the exponent of the core loss curve, the core loss, and the windage and friction may be calculated with the use of the equations derived. An example is given of the close agreement with the test curve in the case of an induction motor; and other examples are cited of close agreement of the core loss and windage and friction losses with the losses measured by means of the usual belted method. The fact is pointed out that in some machines more accurate results are obtainable by means of the proposed method than with the usual belted method.

THE usual method of measuring iron, and friction and windage losses in direct-current and synchronous alternating-current machinery consists in driving by belt from a small direct-current motor and measuring the power input. This method has three disadvantages: (a) The losses in the belt, and the losses in the driving motor are somewhat uncertain, especially the former; (b) the driving motor belt, and possible other auxiliaries require extra floor space, and necessitate equipment which may not be available or difficult of application; and (c) in driving some machines, especially turbo-generators with large stored energy in rotating parts, it is difficult to average with accuracy the current input to the driving motor.[1] The method outlined below may at times necessitate equipment which is not available, or it may require more changes than would warrant its use.

The method is one that has been used frequently. We believe, however, that the method of separation of iron from friction and windage losses is new. It consists in operating the machine idle as a motor, at constant speed, with various voltages impressed across the armature, the watts input to the armature being measured. In the case of a d-c. machine, the excitation and voltages are simultaneously changed so as to maintain constant speed. With synchronous a-c. machines, it is desirable to maintain approximately unity power factor by altering the excitation with the voltage, although slight departure from minimum current will not introduce appreciable errors. With induction machines, the method is the usual idle running saturation curve—the voltage being varied and frequency kept constant. It is advisable to employ integrating instruments for the power, although in some cases indicating instruments will give satisfactory results.

In d-c. and a-c. synchronous machines, the armature $I^2 R$ loss is usually negligible, but in induction machines, this loss is, in general, of appreciable magnitude, and should, therefore, be deducted from the power input.

If we plot volts as abscissas, and power input to the armature[2] (or primary, if an induction motor) as ordinates, the curve will be like that shown in Fig. 1. It is well known that, in many machines, if the laminated iron subject to cyclic changes in flux densities is worked above the knee[3] of the B-H curve, there is stray flux produced which may, by its rate of change, induce electromotive forces in parts external to the laminated iron structure, and such differences of potential may cause currents to circulate, and thereby give rise to by

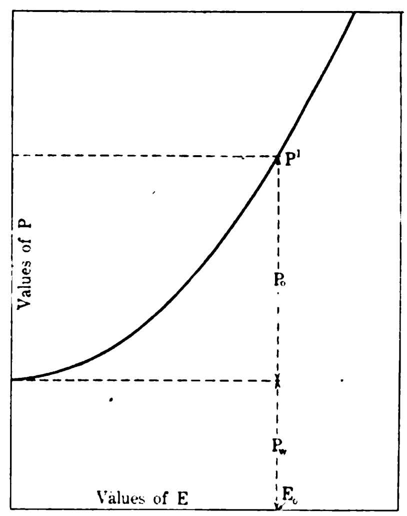

FIG. 1

no means negligible losses. If this condition obtains, the total so-called iron losses augment at a higher rate than ordinarily and we shall, therefore, consider only that part of the loss curve below the point at which the

To be presented at the Midwinter Convention of the A. I. E. E. New York, February 19, 1920.

1. The author believes that the belt friction loss may vary while taking observations when driving large turbo generators, which may introduce an additional error.

2. It is understood that if the $I^2 R$ losses in the armature or primary are appreciable, they must be deducted from the power input.

3. We appreciate that "knee" of curve is liable to be misleading. It appears to us, that with ordinary iron, the departure referred to begins around 12,000 lines per sq. cm. in the core, and 16,500 lines per sq. cm. in the teeth. In giving the method of separation to our Testing Department we have asked them to select the high point at approximately 90 per cent of normal voltage.

high loss gradient begins. We may then write the equation of the curve:

$$P = P_w + P_0\,(E/E_0)^n \qquad (1)$$

Where E = any voltage,

E_0 = voltage below "knee" of B-H curve,

n = constant exponent which indicates the rate at which iron loss increases with voltage,

P_0 = iron loss at voltage E_0,

P_w = friction and windage loss (constant at constant speed),

P = total loss = sum of friction and windage and iron losses.

Or, transposing P_w and taking natural logarithms,

$$\log_e (P - P_w) = \log_e (P_0/E_0)^n + n \log_e E \qquad (2)$$

Differentiating with respect to E, and remembering that $(P_0/E_0)^n$ is a constant,

$$\frac{1}{(P - P_w)}\,\frac{d\,p}{d\,E} = \frac{n}{E} \qquad (3)$$

Or, solving, $$P_w = P - \frac{E}{n}\left(\frac{d\,p}{d\,E}\right) \qquad (4)$$

Select two points[4] on the curve;

For the first:

$$P = P_1 \quad E = E_1 \quad \text{and} \quad \left(\frac{d\,p}{d\,E}\right) = \left(\frac{d\,p}{d\,E}\right)_1;$$

For the second:

$$P = P_2 \quad E = E_2 \quad \text{and} \quad \left(\frac{d\,p}{d\,E}\right) = \left(\frac{d\,p}{d\,E}\right)_2$$

Then,

$$P_w = P_1 - E_1/n\left(\frac{d\,p}{d\,E}\right)_1 = P_2 - E_2/n\left(\frac{d\,p}{d\,E}\right)_2 \qquad (5)$$

Whence

$$n = \frac{E_2\left(\frac{d\,p}{d\,E}\right)_2 - E_1\left(\frac{d\,p}{d\,E}\right)_1}{P_2 - P_1} \qquad (6)$$

In this equation, all quantities in right-hand member may be determined from the curve; $\left(\frac{d\,p}{d\,E}\right)_1$ is the slope of curve at point (1) determined by drawing tangent to curve at that point, etc.

Having found n, we may substitute in (5), and evaluate P_w; or we may solve for P_w without solving for n, thus:

$$P_w = \frac{E_2 P_1\left(\frac{d\,p}{d\,E}\right)_2 - E_1 P_2\left(\frac{d\,p}{d\,E}\right)_1}{E_2\left(\frac{d\,p}{d\,E}\right)_2 - E_1\left(\frac{d\,p}{d\,E}\right)_1} \qquad (7)$$

Finally, if P' = power input at normal voltage, E_0

$$P_0 = P' - P_w \qquad (8)$$

We now have all of the constants in equation (1), and the curve may readily be checked by calculating a number of points.

4. See previous foot-note in regard to "knee" of curve for selection of higher point.

We give below data from a typical test curve of a three-phase induction motor; the equivalent single-phase resistance (1.5 × resistance between terminals) = 0.0438 ohm.

TABLE I

Volts	Amperes	Watts input	I^2R	Watts-I^2R
220	104	3640	475	3165
200	93	3210	380	2830
175	80	2730	280	2450
150	68	2320	202	2118
125	57.5	1940	145	1795
100	47	1640	97	1543
75	36.5	1410	59	1351

We shall plot (Watts − I^2R) against volts as in Fig. 2. If we draw tangent to curve at point E_2 = 185 volts, we obtain $\left(\frac{d\,p}{d\,E}\right)_2$ = 15.15, and P_2 = 2600 watts. Similarly, for point 1, we take E_1 = 85 volts, P_1 = 1420 watts, $\left(\frac{d\,p}{d\,E}\right)_1$ = 7.9.

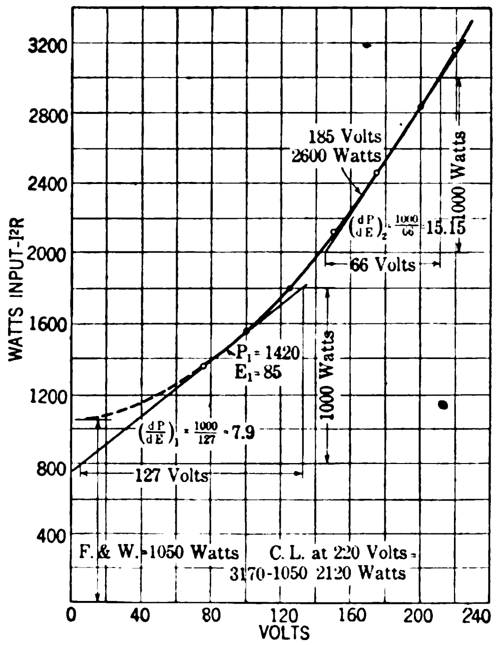

Fig. 2

Substituting in equation (6)

$$n = \frac{185 \times 15.15 - 85 \times 7.9}{2600 - 1420} = 1.81, \text{ the exponent}$$

for iron loss.

Then from equation (5),

$$P_w = 2600 - \frac{185}{1.81} \times 15.15 = 1050 \text{ watts friction}$$

and windage.

From equation (8), $P_0 = 3170 - 1050 = 2120$ watts iron loss at 220 volts. Substituting in equation (1),

$$P = 1050 + 2120\left(\frac{E}{220}\right)^{1.81}$$ is the equation of the curve.[5]

5. In this case, the iron is worked below "saturation" at normal voltage, so that we have taken E_0 to correspond to normal voltage of 220.

We now give the values of watts $- I^2 R$ as determined from test (table I) and those calculated from the equation:

TABLE II

Volts	Watts-I^2R	
	Test	Calculated
220	3165	3170
200	2830	2830
175	2450	2450
150	2118	2092
125	1795	1812
100	1543	1558
75	1351	1350
0	....	1050

It will be found that Fig. 3 is useful in evaluating $E/E_0)^n$ or $(E_0/E)^n$. Plotting K as abscissas and K^n as ordinates on logarithmic paper, gives a straight line which may also be useful.

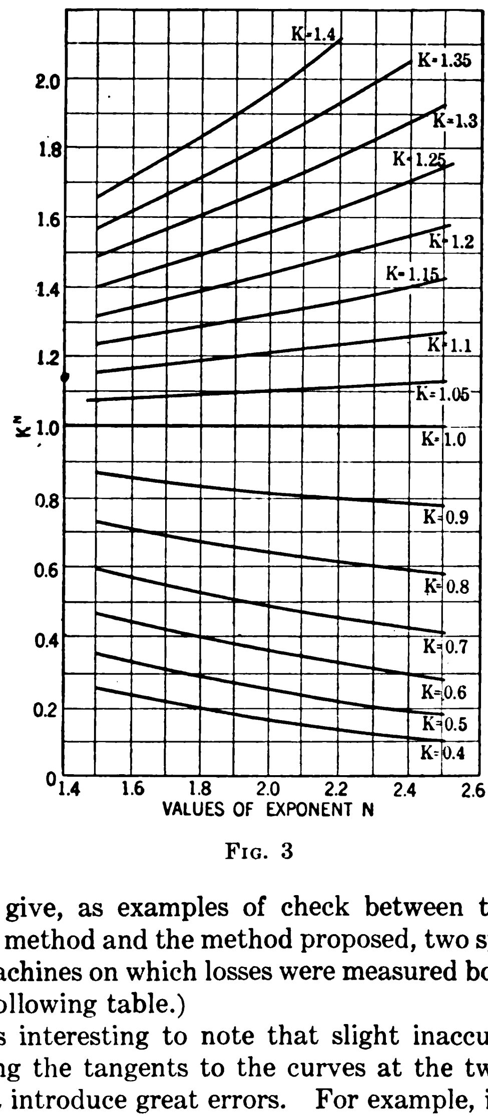

Fig. 3

We give, as examples of check between the usual belted method and the method proposed, two synchronous machines on which losses were measured both ways. (See following table.)

It is interesting to note that slight inaccuracies in drawing the tangents to the curves at the two points do not introduce great errors. For example, in Fig. 2, the tangent at point 2 can be drawn but little, if any, different from that indicated; but at point 1, we might, as extreme with not careful work, draw the tangent so that its slope $\left(\frac{d\,p}{d\,E}\right)$ is 8.3 instead of 7.9. This gives for the exponent "n" 1.774 instead of 1.81 and for P_w 1020 watts instead of 1050 and for P_0 2145 instead of 2120. The difference in friction and windage is thus 3 per cent and in core loss 1.2 per cent. Although this example does not so indicate the exponent "n" usually changes by a larger percentage with slight changes in tangents than does the friction and windage or core loss. Also in the example, the exponent is less than 2, whereas in those synchronous machines which we have investigated, the exponent is slightly above 2.[6]

Maching rating				Kw. core loss at nor. voltage		Kw. friction and wind		
Kv-a.	Volts	R.P.M.	Ph.	Belt	Proposed method	Belt	Proposed method	Remarks
1340	2200	900	3	16.1	16.4	28.	27.6	Part of m-g. set
10,000	4160	1800	3	129.5	124*	143.5	144	Turbo generator

*Machine was warm when making this test, which lowered the iron loss slightly. Machine was started cold for belted test.

In using this method of separation of no load losses, we suggest the advisability of adopting a large scale, especially for the power. For example, if in Fig. 2, had we selected the zero of ordinates to be 1000, we could have doubled the scale and still have plotted the curve on standard cross section paper.

We have obtained quite reliable results with synchronous machines by allowing the integrating wattmeter to run three minutes for each reading. Much depends upon the steadiness of voltage and frequency. It is doubtful whether integrating instruments can be employed to equal advantage with direct current, owing to the fact that such instruments are less reliable than for alternating current.

We have used the method success fully with a 13,500 kv-a. turbo generator, the normal speed of which was 2185 rev. per min. In that case, it was found difficult to obtain consistent data with the ordinary belt method, owing probably, in part, to change in belt loss. We have not experienced difficulty in starting polyphase synchronous machines, having simultaneously brought up to speed the turbo generator and the machine supplying power to it.

While the foregoing application is outlined for separation of iron loss from friction and windage loss, and determination of the equation of the iron loss curve below saturation, it is obvious that it may be applied to any problem in which the general equation is similar in form.

6. Several years ago, the writer observed when plotting on logarithmic paper, core loss curves of synchronous machines (taken by belted method), that the exponent was greater than 2, even below those densities which correspond to beginning of saturation. It would be interesting to have explanations from Institute members.

A Precision Galvanometric Instrument for Measuring Thermoelectric E. M. FS.

BY T. R. HARRISON and PAUL D. FOOTE

Both of the U. S. Bureau of Standards

A new principle has been developed whereby an ordinary millivoltmeter may be converted into an instrument in which the usual errors arising from a variable line resistance are entirely eliminated. The instrument measures true e.m.f. in a simple circuit or if connected across a resistance or network through which a current flows it indicates the potential drop which would have existed had the instrument not been connected. In this respect it functions as a potentiometer, yet it does not operate on the potentiometric principle since it does not require a standard cell (or the equivalent) or an auxiliary battery, the only e.m.f. employed in the adjustment being that of the source measured. No loss in precision of setting results; in fact the adjustment may be readily made to 10 times the scale accuracy. Various wiring diagrams are shown and methods are discussed for constructing instruments of zero temperature coefficient and properly damped. A new deflection potentiometer is described which offers (considerable advantage over the ordinary type for small e.m.fs. in a circuit of variable resistance.

THE maximum e.m.f. developed by a rare-metal thermo-couple is about 15 to 18 millivolts, and that developed by a base-metal couple about 50 to 80 millivolts. To measure such small e.m.fs. accurately by a galvanometric method requires the use of specially constructed millivoltmeters. A millivoltmeter, although graduated to read e.m.f. is fundamentally a current-measuring device. The deflection of the pointer is approximately proportional to the current flowing through the instrument.

If e is the e.m.f. developed by the couple, R_g the resistance of the galvanometer, and R the resistance of the lead wires and couple, the current flowing $= \frac{e}{(R_g + R)}$. Hence in order that a certain deflection correspond to a definite e.m.f., the scale of the instrument must be graduated for a preassigned value of $R_g + R$. Any change in the resistance R from this standard value causes an error in the observed reading of the e.m.f. Such variations may arise from bad contacts, deterioration of the couple, change in depth of immersion, temperature coefficient of lead wires and couple, etc.

In order to minimize the effects of these variations the resistance R_g of the galvanometer is made large compared to that of the line and couple R. This latter resistance in general practise may vary from 1 to 15 ohms. Hence the resistance R_g must be very great in order that changes in R be negligible. The construction of a millivoltmeter having the combined features of high resistance and robustness sufficient to resist the mechanical shocks to which it is necessarily subjected in any industrial plant is an exceedingly difficult problem. The highest resistance ever employed is about 1200 ohms, and instruments are manufactured having a resistance of only 10 ohms. All questions considered, the most satisfactory pivot instruments from the pyrometric standpoint have a resistance of about 5 to 10 ohms per millivolt.

If an instrument having a resistance of 100 ohms is calibrated to read correctly for a line and couple resistance of 2 ohms, and if the resistance of the latter for one of the various reasons mentioned above changes from 2 to 5 ohms, the indicator will read in error by 3 per cent or 30 deg. at 1000 deg. cent. With a 10-ohm indicator the error would be about 20 per cent, or 200 deg. at 1000 deg. cent. Such errors are of serious importance, and are not easily detected unless measurements of the line resistance are frequently made. These measurements require the use of an auxiliary instrument such as a Wheatstone bridge, and then corrections must be applied to the observed reading of the millivoltmeter to take account of the variation in line resistance from the value for which the indicator was standardized.

In the following discussion an instrument is described in which provision is made whereby the total resistance of the circuit may be easily adjusted to the preassigned value for which the scale of the instrument is graduated without requiring the use of any auxiliary instrument or a source of e.m.f. other than that of the couple being measured. Although the instrument was designed primarily for pyrometric purposes, its usefulness is not confined to this field alone.

DESCRIPTION OF COMPENSATED INSTRUMENT

Fig. 1 illustrates the apparatus in a general form. When the instrument is used as a simple temperature indicator, the resistance of the circuit through which the

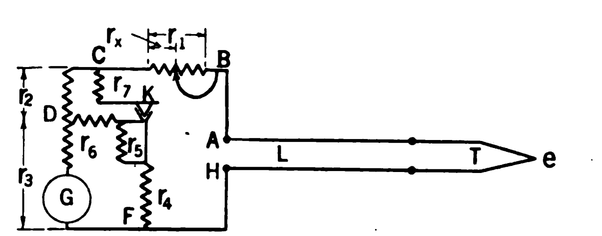

FIG. 1—GENERAL DIAGRAM OF APPARATUS FOR ELIMINATING ERRORS DUE TO UNKNOWN LINE RESISTANCE, FROM WHICH TWO SIMPLE TYPES ARE DERIVED

current from the thermocouple flows is made up as follows: The resistance T of the thermocouple, resistance L of the line or lead wires, a rheostat of resistance r_x which may be adjusted thus altering the resistance of the circuit, a resistance r_2, a resistance r_3 including the resistance of the moving element, r_3 being shunted by

To be presented at the Midwinter Convention of the A. I. E. E., February 20, 1920.

resistance r_4, r_5, and r_6 connected in series. In addition to these parts of the circuit, arranged as shown in the figure, there is a resistance r_7 connected between points C and K, and a key K which when closed, short circuits r_5, and connects r_4, r_6, and r_7 directly together through the key.

By adjusting one or more of the resistances until a definite relation is obtained between the deflections of the moving element G when the key is open and closed respectively, a definite relation will be established between different resistances of the system. The most convenient relation between the respective deflections is identity, and this relation will be used in the following discussion. In the general case here described, identical readings could be established by adjusting any of the resistances r_x, r_2, r_3, r_4, r_5, r_6, or r_7, but it will appear directly that one desirable method is to adjust r_x, for then the sum of r_x, L, and T is brought to a definite value. The instrument may be so designed that when $r_x + L + T$ = a constant $= r_1$, the total resistance of the circuit is the preassigned value for which the instrument was calibrated. The relation between the resistances may be deduced as follows:

Representing the current flowing through r_3 by i'_3 when the key is open and by i_3 when the key is closed, and the e.m.f. which the couple develops by e, when the key is open we have:

$$\frac{e}{i'_3} = r_1 + r_2 + r_3 + \frac{(r_1 + r_2)\, r_3}{r_4 + r_5 + r_6} \tag{1}$$

When the key is closed we have from Kirchhoff's laws the following seven equations:

$$\begin{aligned}
i_1 - i_2 - i_7 &= 0 \\
i_2 - i_6 - i_3 &= 0 \\
i_3 + i_4 - i_1 &= 0 \\
i_7 + i_6 - i_4 &= 0 \\
i_2 r_2 - e + i_1 r_1 + i_3 r_3 &= 0 \\
i_2 r_2 + i_6 r_6 - i_7 r_7 &= 0 \\
i_3 r_3 - i_4 r_4 - i_6 r_6 &= 0
\end{aligned}$$

in which i with subscript represents the current through the resistance designated by the corresponding subscript.

Solving these equations we obtain:

$$\begin{aligned}
\frac{e}{i_3}\,[r_4\,(1 + r_2/r_6) + r_7\,(1 + r_4/r_6)] \\
= r_7 \left[\frac{(r_1 + r_2)\, r_3}{r_6} + (r_1 + r_2 + r_3)\,(1 + r_4/r_6) \right] \\
+ (r_1 r_3 + r_1 r_4 + r_3 r_4)\,(1 + r_2/r_6) + r_2\,(r_1 + r_4)
\end{aligned} \tag{2}$$

If the deflection of the galvanometer is the same whether the key is open or closed, the current flowing through the galvanometer coil is equal in the two cases ($i'_3 = i_3$) and we may substitute for e/i_3 in (2) the value given for e/i'_3 in (1). Upon simplification of the equation thus obtained we have (3) which is the general conditional equation for the relation between the resistances necessary in order that the deflection of the galvanometer be not altered by closing the key K:

$$r_2 r_4 + \frac{r_3\,(r_1 + r_2)\,(r_2 r_4 + r_4 r_6 - r_5 r_7)}{(r_2 + r_6)\,(r_4 + r_5 + r_6)} = r_1 r_3 + \frac{r_2 r_6\,(r_1 + r_4)}{r_2 + r_6} \tag{3}$$

By assigning certain special values to some of the resistances, equation (3) may be very much simplified.

Making $r_5 = \infty$ (*i. e.* no connection directly across from one switch contact to the other) we obtain:

$$r_2 r_4 - \frac{r_3 r_7\,(r_1 + r_2)}{r_2 + r_6} = r_1 r_3 + \frac{r_2 r_6\,(r_1 + r_4)}{r_2 + r_6} \tag{4}$$

If in addition to making $r_5 = \infty$ we make $r_7 = 0$ the equation reduces to the form:

$$r_2 r_4 = r_1 r_3 + \frac{r_2 r_6\,(r_1 + r_4)}{r_2 + r_6} \tag{5}$$

and finally, upon making $r_6 = 0$ in addition to making $r_5 = \infty$ and $r_7 = 0$, we have the important relation *viz.*:

$$r_2 r_4 = r_1 r_3 \quad \text{or} \quad r_1 = \frac{r_2 r_4}{r_3} \tag{6}$$

This arrangement will be discussed fully below. If we impose the sole condition that $r_5 = 0$, equation (3) reduces to the form:

$$r_1 = \frac{r_2 r_4}{r_6} \tag{7}$$

This is also a very simple form which possesses the advantage that it is independent of the value of r_7, and therefore of contact resistance at the key. For high sensitivity in adjusting r_1 to the proper value, r_7 should be practically zero and r_4 should be also low in order that a large current may flow through r_1 when the key is closed.

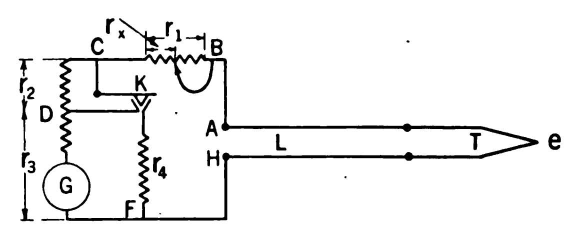

FIG. 2—OPEN SHUNT TYPE FOR HIGH SENSITIVITY, ESPECIALLY SUITABLE FOR THERMOCOUPLES

Fig. 2 shows a diagram of the instrument where $r_5 = \infty$ and $r_6 = r_7 = 0$ as discussed above. The circuit $C\,D\,G\,F$ is an ordinary millivoltmeter or galvanometric indicator of resistance $r_2 + r_3$, the latter resistance including that of the moving element G. In series with this is an adjustable rheostat $C\,B$, the maximum value r_1 of which is chosen equal to the maximum value of the resistance of the line and couple likely to occur in

practise. The galvanometer is calibrated to read correctly when the total resistance R of the circuit has the preassigned value $r_1 + r_2 + r_3$. If in the construction of the instrument $\frac{r_2 r_4}{r_3}$ is made equal to r_1, then when the rheostat $C\,B$ is adjusted to a value r_x such that the deflection of the instrument is the same whether the key is open or closed, the sum of resistances $r_x + L + T$ must equal r_1 and the resistance $r_x + L + T + r_2 + r_3$ of the circuit with the key open must equal the preassigned value $R = r_1 + r_2 + r_3$ for which the scale of the instrument was graduated. Thus it follows, as will be shown more clearly later, that *the instrument measures true e.m.f. in a simple circuit, or if connected across a resistance through which a current flows it will indicate the potential drop which would have existed had the instrument not been connected. In this respect its action is similar to that of a potentiometer. The principle may be also applied to net work conductors, an extension of which leads to a serviceable deflection potentiometer.*

Equation (**6**) may be deduced in a simple manner as follows: If e represents the e.m.f. developed by the couple, e' the potential drop across $D\,F$ when the key is open, and e'' the potential drop across $D\,F$ when the key is closed, we obtain the equations:

$$e' = \frac{e\,r_3}{L + T + r_x + r_2 + r_3} \qquad (\mathbf{8})$$

and

$$e'' = \frac{e\,r_3\,r_4}{(L + T + r_x)(r_3 + r_4) + r_3\,r_4} \qquad (\mathbf{9})$$

If r_x is so adjusted that these two potential drops and hence the deflections of the indicator are the same, we have on equating (**8**) and (**9**):

$$L + T + r_x = \frac{r_2\,r_4}{r_3} = \text{a constant} = r_1 \qquad (\mathbf{10})$$

by construction. Adjustment of the rheostat alters the readings both when the key is open and closed. A simple process for operating the instrument is accordingly as follows:

1. Read the instrument with the key open.
2. Close the key and adjust the rheostat $C\,B$ until the instrument reads approximately the same as in 1.
3. Repeat 1 and 2 if necessary.

Magnification of Errors

By making r_3/r_4 equal to from 5 to 10, the ease with which the proper setting can be obtained is greatly improved. That this is true will be seen from the following consideration.

If the instrument is calibrated to read correctly when the resistances are related according to the equation $r_1/r_2 = r_4/r_3$ and if the rheostat $C\,B$ is out of adjustment by an amount $\delta\,r_1$, the instrument will read in fractional error, when the key is open, by an amount:

$$\frac{\delta\,e'}{e'} = -\frac{\delta\,r_1}{r_1 + r_2 + r_3}$$

and when the key is closed by an amount:

$$\frac{\delta\,e''}{e''} = -\frac{\delta\,r_1}{r_1 + \dfrac{r_3\,r_4}{r_3 + r_4}} \qquad \text{whence}$$

$$\frac{\delta\,e'}{\delta\,e''} = \frac{r_1\,r_3 + r_1\,r_4 + r_3\,r_4}{(r_3 + r_4)(r_1 + r_2 + r_3)} \qquad (\mathbf{11})$$

If $r_1 = r_2$ and $r_3 = r_4$, the above expression simplifies to $\frac{\delta\,e'}{\delta\,e''} = \frac{1}{2}$ or $\delta\,e'' - \delta\,e' = \delta\,e'$. Therefore when $r_3/r_4 = 1$ the difference between the readings will equal the error in the reading when the key is open. If however, r_2/r_1 and r_3/r_4 are made large, say equal to 10, we find $\frac{\delta\,e'}{\delta\,e''} = \frac{1}{11}$ or $\delta\,e'' - \delta\,e' = 10\,\delta\,e'$. Thus if $r_3/r_4 = 10$, the error when the key is open is only 1/11 of the error when the key is closed, or 1/10 of the difference between the readings when the key is open and closed respectively.

In the process for operating the instrument described it is rarely necessary to make a second adjustment when the resistances r_3/r_4 are in as high a ratio as 10. In position 1, the instrument functions as an ordinary galvanometer. The single setting in position 2 reduces the error in the ordinary galvanometer to 1/11 of itself, which is usually sufficient.

The adjustment for the proper external resistance, if desired, can be made with 10 times the precision necessary. Thus, if the galvanometer can be read to 1/10 of a scale division, the line resistance can be set for an error of only 1/100 of a scale division, which is at least 10 times the accuracy possible with any indicating instrument. Hence the factor of variable line resistance which may give rise to very serious errors is easily and accurately controlled by a simple mechanical adjustment.

Multiple Installation

The device is readily applicable to multiple installations of different line resistances. For multiple point recorders and indicators as many resistances $C\,B$ may be employed as there are couples. These may be inexpensive rheostats having a resistance of approximately 15 ohms each, located in each couple line between the couple and the selective switch. These rheostats may be adjusted in the manner described whenever convenient or necessary. The fact that it is not essential to have the extra resistances adjusted to precisely 15 ohms is of great advantage from the

constructional point of view. The instrument may be calibrated for exactly 15 ohms external resistance. If the adjustable resistances accordingly have values of from 16 to 17 ohms, from 1 to 2 ohms more are cut out of the circuit in the process of obtaining a setting than would be the case if resistances of precisely 15 ohms were employed. In either case, however, the final e.m.f. reading is correct.

The following illustrates a suitable proportioning of resistances for a 300 ohm indicator with $r_3/r_4 = 10$:

$$r_1 = 15 \text{ ohms.}$$
$$r_2 = 150 \text{ ohms.}$$
$$r_3 = 135 \text{ ohms.}$$
$$r_4 = 135/10 \text{ ohms.}$$
$$r_1 + r_2 + r_3 = 300 \text{ ohms.}$$

Proper Damping

In designing an instrument of the type discussed above, care must be taken to avoid excessive over damping when the key is closed. The resistances effective in damping are $R = r_1 + r_2 + r_3$ when the key is open and $R_d = r_3 + \dfrac{r_1 r_4}{(r_1 + r_4)}$ when the key is closed. It is evident that R_d is less than R. If we let $K = r_2/r_1 = r_3/r_4$ the following two relations are obtained:

$$r_1 = \frac{R - R_d}{K + \dfrac{R - R_d}{R}} \qquad (\mathbf{a})$$

$$r_3 = r_1 K \frac{R_d}{R - R_d} \qquad (\mathbf{b})$$

For the simple indicator R is known as soon as the scale range is chosen. Suitable values may be selected for r_1 and K and equation (**a**) solved for R_d. If the simple indicator is not seriously overdamped when its total resistance is R_d, this value of R_d is satisfactory, and r_3 may be computed from equation (**b**). The values of r_2 and r_4 follow from K.

If, however, the simple instrument is too sluggish when its total resistance is R_d, the minimum allowable value of R_d may be determined experimentally, and this value, substituted in equation (**a**), determines r_1 with proper choice of K; whence r_2 and r_3.

Temperature Coefficient

In the method so far described, no account has been taken of the temperature coefficient of the instrument. An increase in the temperature of the instrument causes a slight weakening of the springs which tends to allow a given current flowing through the instrument to produce a greater deflection[1]. This tendency is opposed by the effect of a slight decrease in the magnet strength. The effect of the weakening of the springs is almost always in excess of the effect due to the decrease in magnet strength. Thus an instrument becomes more sensitive to current as its temperature rises. In order that a given deflection shall continue to indicate the e.m.f. marked on the scale, the current which this e.m.f. causes to flow through the instrument must decrease with increasing temperature. This requires that the resistance of the circuit increase slightly with increase in temperature. The construction of the instrument is such that its resistance really does so increase. Nearly all of the moving coils used in millivoltmeters are made of copper, the resistance of which increases about 0.4 per cent of its initial value per degree rise in temperature. The majority of instruments require that from 1/13 to 1/40 of the resistance of the galvanometer be composed of copper in order to neutralize the excess of the effect of weakening of springs over decrease in magnet strength and thus give the instrument a zero temperature coefficient.

For an instrument which is constructed with the proper proportion of copper in the circuit, the value of r_1 should be the same whatever the temperature of the instrument. This requires that the value of $\dfrac{r_2 r_4}{r_3}$ also must not vary with temperature. The resistance of r_2 which is of manganin, is practically independent of temperature, but r_3 is composed partly of copper, since it includes the moving element. Therefore in order that r_4/r_3 shall remain constant with changing temperature, r_4 must be composed of the same proportion of copper and manganin as r_3.

Any greater proportion of copper in the instrument than that required as stated above will result in too great a rate of increase of resistance with increase in temperature, and hence the instrument will read too low when its temperature is higher than that at which it was calibrated. Instruments are often made with a greater proportion of copper than is thus required in order to secure a more substantial design suitable for industrial practise and to avoid other difficulties which arise in the construction. One method of making such an instrument read correctly at different room temperatures would be to reduce manually the resistance of the circuit by an amount equal to the increase in resistance of this extra amount of copper in the circuit. The instrument described in the present paper may be arranged so that this compensation is included in the adjustment for variable line resistance without any extra constructional features or manipulation. This is done by allowing the resistance r_4 to have a greater proportion of manganin to copper than r_3. The necessary proportion is found as follows:

Let Q = temperature coefficient of the simple indicator.

P = temperature coefficient of the compensated indicator.

η = temperature coefficient of simple indicator contributed by the copper.

1. See Bureau of Standards Circular No. 20.

ν = temperature coefficient of simple indicator contributed by springs and magnet.

α = temperature coefficient of r_3.

β = temperature coefficient of r_4.

η' = temperature coefficient of compensated indicator contributed by all changes in resistance.

The total temperature coefficient of an indicator is made up of the two parts, the temperature rate of change per ohm of resistance and the combined coefficient of the springs and magnet. Hence for the simple indicator we obtain:

$$Q = \eta + \nu = \frac{\frac{d}{dt}(r_1 + r_2 + r_3)}{r_1 + r_2 + r_3} + \nu$$

$$= \frac{\frac{d\,r_3}{dt}}{r_1 + r_2 + r_3} + \nu \qquad (12)$$

since r_1 and r_2 are constants. For the compensated indicator, however, $r_1 = \frac{r_2 r_4}{r_3}$ is a function of the temperature since both r_3 and r_4 depend upon the temperature. Hence:

$$P = \eta' + \nu = \frac{\frac{d}{dt}(r_1 + r_2 + r_3)}{r_1 + r_2 + r_3} + \nu$$

$$= \frac{\frac{d\,r_1}{dt} + \frac{d\,r_3}{dt}}{r_1 + r_2 + r_3} + \nu$$

$$= \frac{r_1\left(\frac{1}{r_4}\frac{d\,r_4}{dt} - \frac{1}{r_3}\frac{d\,r_3}{dt}\right) + \frac{d\,r_3}{dt}}{r_1 + r_2 + r_3} + \nu \qquad (13)$$

since $$\frac{d\,r_1}{dt} = \frac{r_2 r_4}{r_3}\left(\frac{1}{r_4}\frac{d\,r_4}{dt} - \frac{1}{r_3}\frac{d\,r_3}{dt}\right)$$

$$= r_1\left(\frac{1}{r_4}\frac{d\,r_4}{dt} - \frac{1}{r_3}\frac{d\,r_3}{dt}\right)$$

If in equations (**12**) and (**13**) we substitute

$$\alpha = \frac{1}{r_3}\frac{d\,r_3}{dt} \quad \text{and} \quad \beta = \frac{1}{r_4}\frac{d\,r_4}{dt}$$

we obtain the following:

$$Q = \frac{r_3\,\alpha}{r_1 + r_2 + r_3} + \nu \qquad (12)'$$

$$P = \frac{r_1(\beta - \alpha) + r_3\,\alpha}{r_1 + r_2 + r_3} + \nu \qquad (13)'$$

Whence:

$$P = Q + \frac{r_1(\beta - \alpha)}{r_1 + r_2 + r_3} = \text{temperature coefficient of compensated indicator.} \qquad (14)$$

In order to obtain the condition for an instrument of zero temperature coefficient put $P = 0$ in the above equation, whence:

$$\frac{r_1(\alpha - \beta)}{r_1 + r_2 + r_3} = Q \quad \text{(condition for zero temperature coefficient)} \qquad (15)$$

The coefficients α and β are due to the copper content in the resistances r_3 and r_4. If we assume the temperature coefficient of copper to be 0.004 we obtain:

$$\alpha = \frac{\text{per cent of copper in } r_3}{25{,}000}$$

$$\beta = \frac{\text{per cent of copper in } r_4}{25{,}000}$$

On substituting these values of α and β in equation (**15**) the following equation is obtained for the condition that the compensated indicator have a zero temperature coefficient:

(per cent of copper in r_3) − (per cent of copper in r_4)

$$= 25{,}000\,\frac{r_1 + r_2 + r_3}{r_1}\,Q \qquad (16)$$

If the simple indicator has been so designed that its temperature coefficient is zero, *i. e.* $Q = 0$, equation (**16**) shows that the copper to manganin ratio should be the same in the two resistances r_3 and r_4.

If the simple indicator has a too high copper content so that its temperature coefficient for voltage is positive, *i. e.* $Q > 0$, the experimentally determined value of Q for the simple indicator and the known copper ratio in r_3 may be substituted in equation (**16**) and the proper copper ratio for the shunt r_4 may be readily computed.

Perfect compensation cannot be obtained if $\frac{r_1}{(r_1 + r_2 + r_3)}$ is small and Q is large. The greatest degree of compensation is then secured when r_4 is made entirely of manganin, *i. e.* $\beta = 0$. Hence on making $\beta = 0$, from equation (**15**), we obtain as a condition for the possibility of perfect compensation that:

$$Q \leq \frac{r_1\,\alpha}{r_1 + r_2 + r_3} \qquad (17)$$

Many simple indicators have a temperature coefficient Q which is larger than the maximum value expressed by equation (**17**). In this case the shunt r_4 should be constructed entirely of manganin and the relation between the temperature coefficient of the compensated indicator, P, and that of the simple indicator, Q, readily derived from equations (**12**) and (**13**), is as follows:

$$P = Q\left(1 - 0.004\,\frac{r_1}{r_3 Q}\cdot\frac{\text{ohms of copper in } r_3}{r_1 + r_2 + r_3}\right) \qquad (18)$$

or

$$P = (\eta + \nu)\left(1 - \frac{r_1}{r_3}\,\frac{\eta}{\eta + \nu}\right) \qquad (19)$$

Equation (**19**) is useful for computing directly the value of P on the assumption of a definite value for ν. Usually ν is approximately equal to $-$ 0.0002. We will consider the application of the above equations to the instrument already described.

$$r_1 = 15 \text{ ohms.}$$
$$r_2 = 150 \text{ “}$$
$$r_3 = 135 \text{ “}$$
$$r_4 = 13.5 \text{ “}$$
$$r_1 + r_2 + r_3 = 300 \text{ “}$$

Let $r_3 =$ 50 ohms copper + 85 ohms manganin.

$Q = +\,0.00047$ (assumed to be determined by experiment).

On applying the test given by equation (**17**) it is found that $Q > \dfrac{r_1\,\alpha}{(r_1 + r_2 + r_3)}$. Hence perfect compensation is impossible for the above instrument. By making the shunt entirely of manganin, we obtain on substituting the proper values in equation (**18**):

$$P = (0.00047)\,(0.84) = 0.00040$$

Thus the compensated indicator has a temperature coefficient 16 per cent smaller than that of the simple indicator. The same conclusion follows also from equation (**19**).

Use of the Compensated Millivoltmeter for Measuring Potential Drop

It is at times desirable to measure a small potential drop across a resistance through which a current is flowing. When an ordinary millivoltmeter is employed for this purpose, the potential drop is altered to some lower value which is indicated by the instrument, provided it is graduated to read potential difference at its terminals or at the ends of calibrated lead wires. A similar reading may be obtained with the instrument here described if the rheostat $C\,B$ is set at a marked position such that $r_x = r_1$, since with this adjustment the instrument measures potential drop across its terminals.

Often however, the measurement actually desired is the potential drop which existed across the resistance without the millivoltmeter being connected. This value which may be obtained potentiometrically is also readily measured by the compensated indicator, as will be seen in the following section. When the rheostat $C\,B$ is so adjusted that the deflection of the instrument is the same with the key open or closed, the reading is the potential drop which would exist were the instrument disconnected. One method employed for compensating for irreproducibility of the temperature-e.m.f. relation of different thermocouples of a given type is by the use of shunt and series resistance in the head of the couple.[2]

2. See Foote, Harrison and Fairchild, "Thermoelectric Pyrometry," Pyrometer Symposium, Chicago, 1919.

An ordinary millivoltmeter reads the potential drop existing across the shunt when the instrument is connected. This value depends upon the resistance of the indicator. The reduction in the observed e.m.f. of the couple (potential drop across the shunt) is greater the lower the resistance of the meter. With the compensated indicator however, the ratio of the shunt and series resistances may be definitely adjusted and the instrument, regardless of its resistance, will always indicate, similarly to a potentiometer, that proportion of the e.m.f. e developed by the couple which is represented by the expression

$$e \cdot \frac{\text{shunt resistance}}{(\text{shunt resistance} + \text{series resistance})}\,.$$

Deflection Potentiometer

The compensated indicator may be used as a galvanometer in conjunction with an ordinary potentiometer of low resistance forming a perfectly compensated deflection potentiometer, the compensation being effected by the adjustment of r_x in the manner already described.

This is shown in the following discussion, a special case of which resolves itself to the condition above mentioned in which the instrument may be used to measure the potential drop, which existed before the instrument was connected, over a resistance carrying a current.

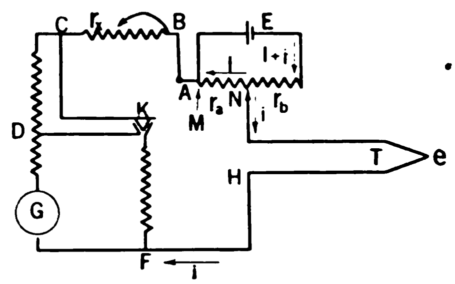

Fig. 3—In Conjunction With any Potentiometer of low Resistance the Instrument Produces a Perfectly Compensated Deflection Potentiometer

Fig. 3 illustrates the use of the instrument as a deflection potentiometer. The potentiometer circuit consists of the battery E and the resistances r_a and r_b the latter including the internal resistance of the battery. When the indicator or galvanometer circuit is broken, for example at A, the potential drop e_1, across r_a is given by equation (**20**):

$$e_1 = \frac{r_a}{r_a + r_b}\,E \qquad (\mathbf{20})$$

Upon connecting the instrument to the potentiometer so that the e.m.f. e of the thermocouple (or any source of e.m.f.) T opposes e_1, the currents flowing through r_a and r_b are unequal and different from the original value. Assume that the currents now flowing are as indicated in the figure, I being the current in r_a, i the current in the indicator or galvanometer circuit,

and $I + i$ the current in r_b. Since the sum of e.m.fs. and potential drops around any closed circuit is zero, the following two equations may be written:

$$E = (r_a + r_b)\, I + r_b\, i \qquad (21)$$

$$e = r_a I - R\, i \qquad (22)$$

in which R equals the resistance of the circuit from M, through $A\ B\ C\ D\ F\ H$ etc. back to N. Substituting the value of I from equation (**21**) in equation (**22**) and subtracting this value of e from the value of e_1, given by equation (**20**) we obtain:

$$e_1 - e = i\left(R + \frac{r_a r_b}{r_a + r_b}\right) \qquad (23)$$

This is the equation of a deflection potentiometer.[3]

If now the resistance r_x is so adjusted that the reading of the instrument is the same whether the key K is closed or open, we have the following relations: Representing the values of i with the key open and closed respectively by i' and i'', we have for the potential drops across $D\ F$ in the two cases, $i'\, r_3$ and $i''\, \dfrac{r_3 r_4}{r_3 + r_4}$.

Equating these we obtain:

$$i'' = i'\, \frac{r_3 + r_4}{r_4} \qquad (24)$$

the condition necessary for equal deflections.

We also have the values R' and R'' for R with the key open and closed respectively.

$$R' = r_x + L + T + r_2 + r_3 \qquad (25)$$

$$R'' = \frac{(r_x + L + T)\,(r_3 + r_4) + r_3 r_4}{r_3 + r_4} \qquad (26)$$

From equation (**23**) it follows that:

$$e_1 - e = i'\left(R' + \frac{r_a r_b}{r_a + r_b}\right) = i''\left(R'' + \frac{r_a r_b}{r_a + r_b}\right)$$

since both e_1 and e are independent of R, e being the e.m.f. of the couple and e_1 being defined by equation (**20**). If the values of R' and R'' from equations (**25**) and (**26**) and the value of i'' in terms of i' from equation (**24**) are substituted in the above equation, we obtain:

$$\frac{r_2 r_4}{r_3} = r_x + L + T + \frac{r_a r_b}{r_a + r_b} \qquad (27)$$

But by the construction of the instrument $r_1 = \dfrac{r_2 r_4}{r_3}$.

Hence from equation (**25**), $R' = \dfrac{r_1 + r_2 + r_3 - r_a r_b}{(r_a + r_b)}$.

If this value of $R = R'$ is substituted in equation (**23**) we obtain:

$$e_1 - e = i\,(r_1 + r_2 + r_3) \qquad (28)$$

3. For general theory and design of deflection potentiometers see Brooks, Bull. Bu. Stds. Vol. 8, 1911, p. 395 (Sci. paper 172) and p. 419 (sci. paper 173).

The compensated indicator is calibrated for a total resistance $r_1 + r_2 + r_3$ so that the current i flowing through the instrument produces a deflection which indicates directly the difference between the e.m.f. e of the couple and the potential drop e_1 existing across r_a with the instrument disconnected. The potentiometer is graduated to read the value of e_1. *Thus when the compensated indicator is used as the galvanometer of an ordinary potentiometer, a deflection potentiometer is obtained which requires no compensation other than that provided by the indicator.*

Evidently the instrument has the disadvantage for continuous use as a deflection potentiometer that a new adjustment is required whenever the dial setting of the potentiometer is changed enough to cause a material difference in the value of $\dfrac{r_a r_b}{(r_a + r_b)}$. In any form of a deflection potentiometer however, changes in the resistance of the couple and leads, unless compensated for, will introduce errors in the galvanometer readings. The ordinary deflection potentiometer may be provided with a rheostat, in series with the couple and galvanometer, which is adjusted until the full scale range is equivalent to one step on the dial. The instrument here described compensates simultaneously for changes in both the couple resistance and potentiometer resistance. This adjustment is simpler than the adjustment for scale sensitivity of the ordinary deflection potentiometer, and hence if the resistance of the couple varies seriously, the new type of deflection potentiometer appears to be the more easily operated.

If in equation (**28**) we let $e = 0$, we obtain the condition which applies when the compensated indicator is connected across a resistance carrying a current. *It follows directly from the reasoning presented above that the instrument indicates the potential drop, e_1, which would exist if the instrument were not connected.*

Calibration of the Compensated Millivoltmeter.

Another useful application of this feature may be employed in calibrating the scale of the indicator. The scheme of connections is the same as that shown in Fig. 3 except that there is no thermocouple T in the circuit. The instrument is connected directly, with the proper polarity to give positive deflections, to the e.m.f. terminals of a potentiometer of sufficiently low resistance that, for all settings, $\dfrac{r_a r_b}{(r_a + r_b)}$ plus the resistance L of any leads employed is not greater than r_1, and the galvanometer terminals of the potentiometer are short-circuited. When the resistance $C\ B$ is so adjusted that the deflection of the indicator is unaltered by depressing the key K, the reading of the potentiometer gives the value of the e.m.f. which should be indicated by the millivoltmeter. The other obvious method of calibrating the instrument in terms of the potential drop across its terminals when the resistance

$r_x = r_1$ is not as simple experimentally, and the former method is applicable at any temperature when the shunt resistance r_4 is constructed with the proper ratio of manganin to copper (see equation **16**) necessary to give a zero temperature coefficient. With the latter method however, the calibration should be made at the temperature for which a definite marked position of the rheostat $C\,B = r_1 = \frac{r_2\,r_4}{r_3}$. This position can be a definite one at only one temperature for a compensated instrument, if the simple indicator has a temperature coefficient. However, the errors likely to arise from not considering this factor are usually of negligible importance.

Use of Compensated Millivoltmeter for Measurement of Potential Drop Across a Network

It follows from the above discussion that the compensated indicator may be used to measure the true potential difference between any two points of a complicated network, existing were the instrument not connected. In this respect the instrument acts as a potentiometer. This is more clearly demonstrated as follows:

In Fig. 4 let r = resistance of network between M and N, excluding branch $M\,P\,N$.

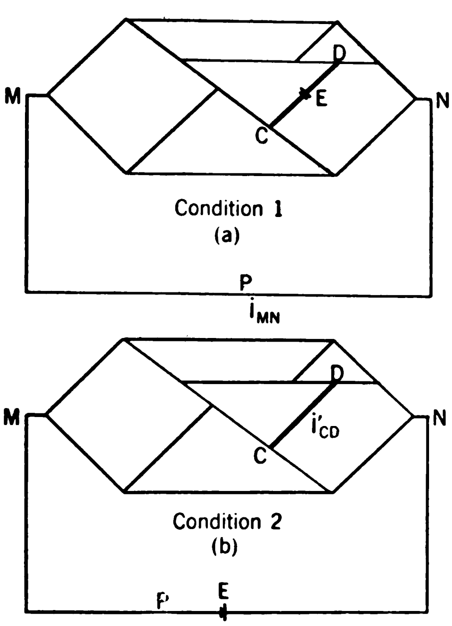

Fig. 4—Showing General Deflection Potentiometer Principle, or Potentiometric Nature of Readings by the Compensated Instrument

R = resistance of branch $M\,P\,N$.

e_2 = potential drop across $M\,N$ for condition 1. Primed letters refer to condition 2, unprimed letters to condition 1.

The current i_{MN} which flows from M to N when an e.m.f. E is introduced in the branch $C\,D$ of the network is equal to the current i'_{CD} which flows from C to D when the same e.m.f. is introduced in the arm $M\,N$[4]. These two conditions are shown by (a) and (b) of Fig. 4.

$$i_{MN} = i'_{CD} \text{ by the above theorem.} \qquad (29)$$

$$i_{MN} = \frac{E}{R + r} \text{ from Ohm's law. Hence:}$$

$$i'_{CD} = \frac{E}{R + r} K \text{ where } K < 1 \text{ is a constant}$$

depending upon the values and the grouping of the separate resistances of the network. Also,

$$i_{MN} = \frac{e_2}{R} = \frac{E}{R + r} K \quad \text{or} \qquad (30)$$

$$e_2 = \frac{E}{1 + r/R} K \qquad (31)$$

When $R = \infty$ let $e_2 = e_1$, whence from equation (**31**) $e_1 = E\,K$. Substituting this value of $K = e_1/E$ in equation (**30**) we obtain:

$$i_{MN} = \frac{e_1}{R + r} \qquad (32)$$

Thus the current flowing in the branch R is equal to the potential drop across $M\,N$ with the branch circuit open divided by the total resistance of the circuit.

Suppose the branch circuit to be the compensated indicator. The current flowing through the instrument is given by equation (**32**), and the two values R' and R'' of R (key open and closed) are expressed by equations (**25**) and (**26**). Hence:

$$\text{Key open } i' = \frac{e_1}{r_x + L + T + r_2 + r_3 + r}$$

$$\text{Key closed } i'' = \frac{e_1}{(r_x + L + T) + \dfrac{r_3\,r_4}{r_3 + r_4} + r}$$

If r_x is adjusted for equal deflections with the key open and closed we may substitute these values of i' and i'' in equation (**24**) and obtain:

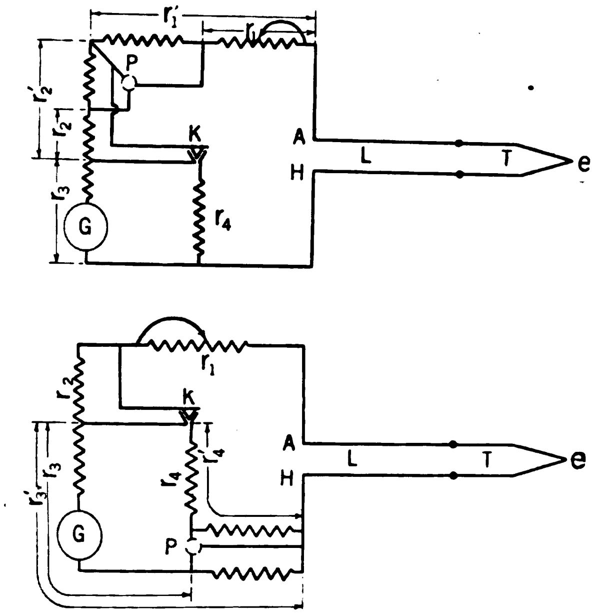
$$\frac{r_2\,r_4}{r_3} = r_x + L + T + r = r_1 \; (33) \text{ as in equation } (27)$$

Thus with the key open $e_1 = i'\,(r_1 + r_2 + r_3)$. The instrument is calibrated for the total resistance $(r_1 + r_2 + r_3)$ so that the current i' produces a deflection which indicates directly the true potential difference e_1 existing between any two points of a net work. If there are several e.m.fs. E_1, E_2, etc. in different arms of the net work, it readily follows that the instrument still measures the true potential drop, on open external circuit, between any two points to which it is connected.

4. Jeans Math. Theory of Elec. and Mag. 3rd Ed. p. 327. See also Maxwell.

Double Scale Range

Figs. 5 and 6 illustrate modifications of the simple design shown in Fig. 2 to permit the use of two different e.m.f scales. In Fig. 5 the resistances r_1 and r_2 are increased in the same ratio and by such an amount that the total resistance $r_1' + r_2' + r_3$ gives the desired sensitivity for the high range scale. Thus $r_1/r_2 = r_1'/r_2' = r_4/r_3$ and the factor for the magnification of errors is the same with either range. With the plug in at P, $r_1' - r_1$ and $r_2' - r_2$ are short-circuited and the instrument operates on the low range scale. With the plug out r_1 is increased by the fixed resistance $r_1' - r_1$ and r_2 is changed to r_2', and the instrument operates on the high range scale.



Figs. 5 and 6—Double Range Instruments, Compensated in Either Range

In the design shown by Fig. 6 the resistances r_3 and r_4 are increased in a similar manner such that $r_1/r_2 = r_3/r_4 = r_3'/r_4'$.

Use of an Unadjustable Value for r_1

In the foregoing discussion adjustment of the resistance r_1, which consists in part of the line and couple, has been considered. As has already been pointed out, if any of the four resistances in Fig. 2 is adjusted to give equal galvanometer deflections with the key open and closed, the relation $r_1/r_2 = r_4/r_3$ will be established.

In Fig. 7, r_3 is made equal to r_4, and its value is chosen such that the instrument reads correctly when the total resistance of the circuit equals $r_2 + r_3 + r_x$ where $r_2 + r_x$ is the total resistance of the rheostat. With this arrangement $r_1 = L + T$. When switch S is in position B', adjustment for equal deflections makes $r_1 = r_2$, (since $r_4 = r_3$). After this adjustment switch S is thrown into position B, and the resistance of the circuit, $L + T + r_x + r_3$ equals $r_2 + r_x + r_3$, the resistance for which the instrument reads correctly. The process of adjusting is to close the key K and read the instrument, open the key and adjust the rheostat until the instrument shows the same deflection, and then throw S into the opposite position. The method has the advantage that the reading with the key closed is independent of the setting of the rheostat; therefore, when adjusting the rheostat with the key open the reading to which the instrument should be brought is

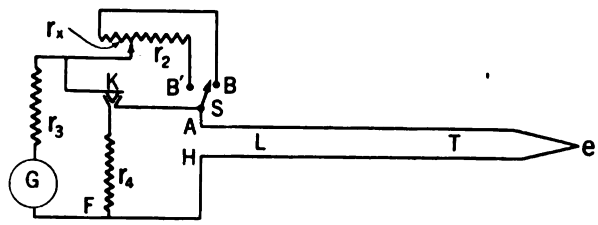


Fig. 7—Modification of Fig. 2

accurately known. It is immaterial which way switch S is set during the adjustment, provided its position is changed after the adjustment has been made. Three disadvantages will be noted. (1) Since $r_3 = r_4$, there is no multiplication of errors in setting; (2) an extra switch S is required, and this switch must be operated each time an adjustment is made; (3) any contact resistance existing in the rheostat will alter the final resistance of the circuit by double this amount. Such contact resistances constitute no error in the instrument shown in Fig. 2.

Fig. 8 shows a design, somewhat similar to that illustrated by Fig. 7, which is modified to give a multiplication of errors on setting. Resistance r_4 is made equal to r_3/m, where m is any desirable factor for

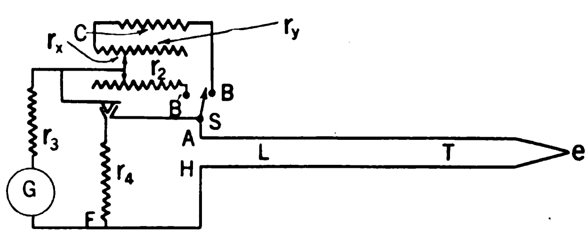

Fig. 8—Modification of Fig. 7 Arranged for Accuracy of Adjustment

multiplication of errors. The total resistance $r_x + r_y$ of the upper rheostat is made equal to the maximum allowable line and couple resistance. The total resistance of the rheostat of which r_2 is part is made equal to $m\ (r_x + r_y)$. Adjustment for equal deflections with switch S at B' makes $r_2 = m\ (L + T)$, whence, since the two rheostats are adjusted simultaneously, $r_y = L + T$. This is removed from the circuit upon setting switch S in working position B. Resistance r_3 in Fig. 8 is made less than r_3 in Fig. 7, in order to compensate for a higher value of r_2. Resistance C is added to bring the total resistance of the circuit in the operating position up to the proper value.

In Fig. 9 the resistance r_4 is adjustable. By construction r_2 is made equal to r_3. Switch S is closed and r_4 is adjusted until equal deflections of the galvanometer are established. This makes $r_4 = r_1 = L + T$. Opening switch S adds resistance r_x to the circuit, making the total resistance equal to $r_2 + r_3 + x$, the resistance for which the instrument is calibrated. With S closed and K open the reading is independent of the setting of the rheostat. This reading is noted. With switches K

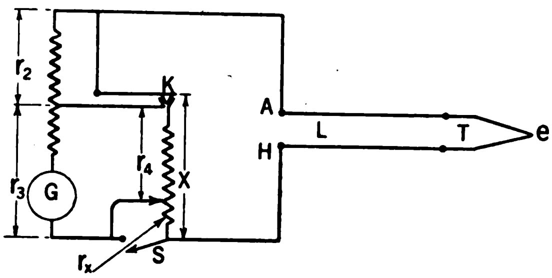

FIG. 9—ANOTHER MODIFICATION OF FIG. 2

and S closed r_4 is adjusted until the reading is the same as that determined above. The factor m increases rapidly as resistance $L + T\ (= r_1)$ decreases. Its value is given by the expression $m = \dfrac{r_2 + r_3 + x}{2\, r_4\, (1 + r_4/r_3)}$.

COMPENSATED MILLIVOLTMETER WITH $r_5 = 0$

The circuit for an instrument designed according to equation (7) in which $r_5 = 0$ is shown by Fig. 10. The instrument possesses many advantages, one of these being the complete elimination of objectionable effects

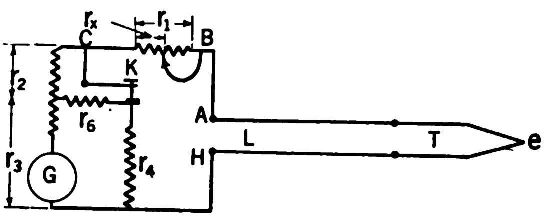

FIG. 10—CLOSED SHUNT TYPE OF COMPENSATING INDICATOR

of contact resistances. It is further possible to compensate for temperature coefficient by the well known Swinburne[5] method, to obtain any desirable magnification ratio for errors, and to secure an instrument which is satisfactorily damped either with the key open or closed. Where a desirable magnification ratio cannot be otherwise obtained a battery may be inserted between c and K, Fig. 10. The proportioning of the various resistances is illustrated by the following discussion:

Let i' = current through the galvanometer coil necessary to produce full scale deflection.

e' = maximum e.m.f. measured = highest scale reading.

5. Hallo and Land, Electric and magnetic measurements and measuring instruments, 1906, p. 260.

R_g = resistance of the moving copper coil.

m = magnification ratio for errors $\left(\dfrac{\text{key closed}}{\text{key open}}\right)$.

R_d = proper damping resistance.

Hence:

$$\frac{(r_3 + r_4 + r_6)\,(r_1 + r_2)}{r_4 + r_6} + r_3 = e'/i' = S \qquad \text{(Scale range)} \quad (34)$$

Equation (**34**) is the condition for scale range such that an e.m.f. e' produces a full scale deflection.

$$r_1/r_2 = r_4/r_6 \qquad \text{(Key adjustment)} \quad (35)$$

Equation (**35**) is deduced as shown by equation (**7**) and expresses the condition that the deflection of the galvanometer is the same with the key K open or closed.

$$r_1 + r_2 = (r_4 + r_6)\,\frac{R_g}{r_3 - R_g} \qquad \text{(Temperature compensation)} \quad (36)$$

Equation (**36**) imposes the condition for temperature compensation by the Swinburne method. The resistances r_4 and r_6 must be of copper.

$$\frac{1}{m} = \frac{\delta\, e'}{\delta\, e''} = \frac{r_1 + r_4 - r_4 \dfrac{r_4}{r_3 + r_4 + \dfrac{r_2\, r_6}{r_2 + r_6}}}{r_1 + r_2 + \dfrac{r_3\,(r_4 + r_6)}{r_3 + r_4 + r_6}} \qquad \text{(Errors)} \quad (37)$$

Equation (**37**) shows the relation between the error in a setting with the key open and with the key closed. This is derived in a manner similar to that employed in the discussion of Fig. 2.

$$R_d = r_3 + \frac{(r_1 + r_2)\,(r_4 + r_6)}{r_1 + r_2 + r_4 + r_6} = r_3 + \frac{(r_1 + r_2)\, r_4}{r_1 + r_4} \qquad \text{(Damping)} \quad (38)$$

Equation (**38**) gives the total resistance of the galvanometer circuit with the key open. This should equal the proper damping resistance which is slightly greater than the critical damping resistance. It will be noted that when the resistance r_x is adjusted for identical deflections with the key open and closed the resistance effective in damping is the same with the key in either position, and hence if the instrument is properly damped with the key open, it will be properly damped with the key closed.

The above 5 equations serve to determine the 5 variables r_1, r_2, r_3, r_4, and r_6. However, the condition for proper damping, equation (**38**), need not be satisfied exactly. The behavior of an instrument usually allows considerable tolerance in the value of R_d. Hence in order to obtain wide limits for construction, the first four equations may be solved as indeterminants and the best values of the resistances consistent with a suitable damping resistance may be chosen for the final design. The third term in the numerator of the

right hand member of equation (**37**) is usually small. In place of equation (**37**) we shall assume the following relation:

$$\frac{1}{K} = \frac{r_1 + r_4}{r_1 + r_2 + \dfrac{r_3\,(r_4 + r_6)}{r_3 + r_4 + r_6}} \qquad (\mathbf{39})$$

The solution of equations (**34**), (**35**), (**36**), and (**39**) is as follows:

$$r_1 = \frac{R_g\,S}{K\,r_3\left[\,1 - \dfrac{r_3\,R_g}{(r_3 - R_g)\,(S - r_3)}\right]} \qquad (\mathbf{40})$$

$$r_2 = S - r_1 - r_3 - \frac{r_3\,R_g}{r_3 - R_g} \qquad (\mathbf{41})$$

$$r_4 = \frac{r_1\,(r_3 - R_g)}{R_g} \qquad (\mathbf{42})$$

$$r_6 = \frac{r_2\,r_4}{r_1} \qquad (\mathbf{43})$$

The following example illustrates the method of applying the above equations: It is desired to convert an ordinary millivoltmeter, scale range 0 – 15 millivolts into the above compensated instrument having a scale range 0 – 60 millivolts. The resistance of the simple indicator is 250 ohms of which the copper content $R_g = 60$ ohms. The instrument if suitably designed is accordingly properly damped on $R_d = 250$ ohms. Since the scale range is to be increased by the factor 4, the value of $S = 4 \times 250 = 1000$ ohms. Let $K = 10$. This is closely equal to m the magnification ratio for sensibility to changes in r_1 with the key closed. For various assumed values of r_3 compute r_1 from equation (**40**). For corresponding values of r_3 and r_1 compute r_2 from equation(**41**). Similarly for equations (**42**) and (**43**).

The following table illustrates the results thus obtained:

Values of Resistances for $r_5 = 0$

r_3	r_1	r_2	r_4	r_6	$r_3 + \frac{(r_1 + r_2)\,(r_4 + r_6)}{r_1 + r_2 + r_4 + r_6}$	m
65	15.3	140	1.27	11.7	77	10.0
70	47	463	7.84	77.3	143	
80	55.5	626	18.5	208.5	250	10.2
90	53.5	676	26.7	338	333	
100	50	700	33.3	466	400	10.3
200	26.8	688	62.5	1605	700	
300	17.85	607	71.4	2428	800	10.7

Any of the above designs gives a millivoltmeter of scale range 0 – 60 millivolts, compensation for temperature coefficient by the Swinburne method and complete elimination of the error due to uncertain line drop. The values corresponding to $r_3 = 80$ furnish the proper damping, 250 ohms, characteristic of the particular instrument selected. If we substitute the values of the various resistances in equation (**37**) we obtain $m = 10.2$ which gives the ratio of sensitivities with the key closed and open.

If equations (**40**) to (**43**) do not furnish satisfactory values for the resistances with a suitable choice for K, equation (**36**) may be omitted and equations (**34**), (**35**) and (**39**) may be solved indeterminately similar to the manner above outlined. If the final choice of values for the various resistances results in an excessive temperature coefficient of the compensated instrument, this can be minimized by making r_4 and r_6 of unequal temperature coefficients, thus allowing the adjustment of r_1 to vary with the temperature as was done with the instrument illustrated by Fig. 2.[2]

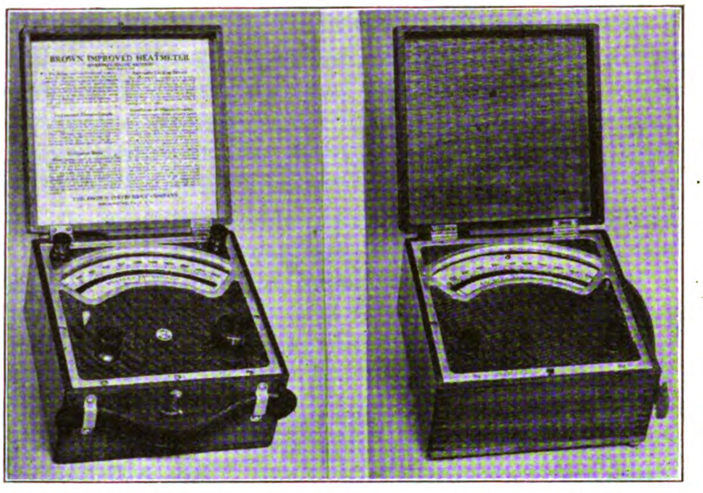

FIG. 11—COMPARISON OF INSTRUMENTS WITH AND WITHOUT COMPENSATING DEVICE. COMPENSATED INSTRUMENT SHOWN ON LEFT

The instrument on the right in Fig. 11 is an ordinary millivoltmeter. The other instrument is the compensated millivoltmeter constructed according to the wiring diagram shown in Fig. 2. It will be noted that the additional wiring requires no alteration in the size of the finished instrument.

SUMMARY

A new principle has been developed whereby an ordinary millivoltmeter may be converted into an instrument in which the usual errors arising from a variable line resistance are entirely eliminated. All of the several modifications described afford some simple means by which the total resistance of the galvano-

6 This method of treatment has recently been developed more fully and will appear in an early issue of the *Journal Wash. Acad. of Sci.* In this treatment the compensation for coefficient of springs and magnet is considered. This condition is more easily satisfied than is that required by eq. (**36**). This method is useful in making low range instruments.

meter circuit, internal and external, is adjusted to a preassigned value for which the scale of the instrument is calibrated. In one form now manufactured the instrument consists of an adjustable resistance r_x in series with the moving coil and swamping resistance of the millivoltmeter. On depressing a key part, r_2, of the swamping resistance is short-circuited and the remaining part together with the moving coil, r_3, is shunted by a resistance r_4. The instrument is calibrated in terms of the potential drop across its terminals for a maximum value of $r_x = r_1$. In the construction the resistances are proportioned according to the relation $r_2 r_4 = r_1 r_3$. If the resistance r_x is so adjusted that the deflection of the pointer is unchanged by depressing the key it is shown that the total resistance of the circuit is that for which the instrument is calibrated, the sum of r_x and all external resistance being thus made equal to r_1. Hence it follows that the instrument measures true e.m.f. in a simple circuit, or if connected across a resistance or network through which a current flows it indicates the potential drop which would have existed had the instrument not been connected. In this respect it functions as a potentiometer, yet it does not operate on the potentiometric principle since it does not require a standard cell or an auxiliary battery, the only e.m.f. employed in the adjustment being that of source measured.

By constructing r_3/r_4 equal to from 5 to 10 it is possible to adjust r_x with 5 to 10 times the precison necessary. Thus if the galvanometer can be read to 1/10 of a scale division the line resistance may be adjusted with a precision equivalent to 1/100 of a scale division, which is at least 10 times the accuracy possible with any indicating instrument. This principle of magnification of errors greatly facilitates the proper adjustment of r_x. By varying the copper to manganin ratio in r_4 it is possible to produce a compensated instrument of zero temperature coefficient from a millivoltmeter having an excessive copper content.

The instrument may be used as a galvanometer with an ordinary potentiometer, forming a deflection potentiometer which requires no compensation other than that provided by the indicator. Such an instrument is especially serviceable in thermocouple work.

The compensated millivoltmeter may be used in multiple installations of thermocouples having different line resistances, as many resistances r_x being employed as there are couples. These may be inexpensive rheostats, one located in each line between the couple and selective switch, and still the accuracy of adjustment will be as high as though precision rheostats were employed.

Methods are described for constructing instruments of double scale range with compensation in both ranges.

Specifications are given for an instrument which compensates for line resistance, which has a zero temperature coefficient, and which is properly damped either with the key closed or open.

NEW WIRELESS PHONE CARRIES 900 MILES

Announcement has just been made that during the past month wireless telephone conversations have been carried on between Ossining, N. Y. and Chicago, a distance of about 900 miles, as well as with cities in Indiana and Ohio, with the use of a small aerial, a 375-meter wave length, and a power of 1/3 of a kilowatt. Mr R. F. Gowan, engineer of the De Forest radio station at Ossining, who made the experiments is quoted in the New York *Times*, as follows:

"The effect of the new circuit is to render the voice transmission much clearer, while the use of a new type of glass permits of much greater input circuit in the development of the wireless power.

"It is further interesting to note that all my experiments are being conducted on a comparatively low wave length—that is to say, the special amateur wave lengths permitted by the Government regulations. In addition, the experiments show that the distance between Ossining and Chicago is covered with only one-third of the energy of which the De Forest oscillion or oscillating audion is capable of developing. In other words, with only one-third kilowatt of input energy in a single tube we are enabled to talk without wires from New York to Chicago.

"We have been able to talk over a distance of 900 miles, but we have today reached the commercial development of the wireless telephone under all conditions, I should say, for a distance of at least 300 miles, that is, a service identical with the long distance telephone.

"The experiments in question have been conducted night after night since Jan. 1, and through the most severe static interference. There has also been tremendous interference from other stations, and yet in spite of all this when I picked up the telephone transmitting apparatus at Ossining and spoke into it, just as any one might speak into the ordinary telephone, I discovered that my voice was being distinctly heard first of all in the little town of St. Mary's, Ohio. The radio amateur at St. Mary's, it seems, was at that time picking up local dots and dashes, and when he heard this voice from out of the air, the sending location of which was reported to be Ossining, N. Y., he was, to say the least, somewhat startled. He immediately answered by sending me a telegraph inquiry which I distinctly heard in my own receiving apparatus. I then repeated my conversation to him and asked him to confirm the conversation immediately by letter. This he did."

In the same way conversations were picked up by amateur stations in Salem, Ohio, Gaffney, S. C., Wakefield, Mass. and Chicago. In all cases the messages were received unexpectedly and without previous arrangement.

EIGHTH MIDWINTER CONVENTION

FEBRUARY 18-20, 1920

The Eighth Annual Midwinter Convention of the American Institute of Electrical Engineers will be held February 18-20, 1920, in the Engineering Societies Building, 33 West 39th Street, New York.

Wednesday, February 18

The Registration Bureau will be located in the Foyer of the building and will open in the morning for the registration of members and guests.

On Wednesday morning there will be a meeting of the Board of Directors of the Institute.

On Wednesday afternoon the alternative is offered of engaging in one of the numerous trips to points of engineering interest, listed in detail elsewhere in this announcement, or of accepting the invitation of the American Institute of Mining and Metallurgical Engineers to attend the final session of its convention in the Engineering Societies Building. At this meeting papers will be presented on the Physical Properties of Iron, Steel and Their Alloys.

Wednesday evening there will be a technical session, opened by an address by President Calvert Townley, followed by the presentation of papers by Preston S. Millar, W. S. Gorsuch and E. J. Cheney.

Thursday, February 19

On Thursday morning a symposium will be presented on "Economical Supply of Electric Power for the Industries and Railroads of the Northeast Atlantic Seaboard." Reference to this Symposium will be found on page 179 of this issue of the JOURNAL.

On Thursday afternoon parallel sessions will be held in the Auditorium and in Room 1, 5th Floor. Papers will be presented by J. H. Bell, G. A. Campbell, R. M. Foster, C. J. Fechheimer, A. I. Ellis, B. W. St. Clair, P. E. Klopsteg and A. L. Loomis.

On Thursday evening there will be a Dinner-Dance at the Hotel Astor for members and guests in attendance at the Convention. Particulars in regard to this function will be found under the heading Entertainment.

Friday, February 20

On Friday two technical sessions will be held, both under the auspices of the Instruments and Measurements Committee.

At the morning session three papers will be presented by P. G. Agnew, J. R. Harrison and P. D. Foote, and J. B. Whitehead and T. Isshiki.

In the afternoon two papers will be presented by A. E. Kennelly, R. N. Hunter and A. A. Prior, and H. B. Brooks.

PROGRAM

Wednesday Morning, February 18

Registration Bureau opens.
Board of Directors Meeting, 10:30 a.m.

Wednesday Afternoon, February 18

AUDITORIUM 2:30 P. M.

Participation in meeting with American Institute of Mining and Metallurgical Engineers.
Alternative: Visits to points of Engineering Interest.

Wednesday Evening, February 18

AUDITORIUM 8:15 P. M.

Address—by the President Calvert Townley.

1. *Daylight Saving*, by Preston S. Millar, Manager Electrical Testing Laboratories. New York.
2. *Essential Statistics for the General Comparison of Steam Power Plant Performance*, by W. S. Gorsuch, Engineer Economics, Interborough Rapid Transit Co., New York.
3. *Standard Graphic Symbols*, by E. J. Cheney, Chief of Division of Heat, Light and Power, Public Service Commission, Albany, N. Y.

Thursday Morning, February 19

ROOM NO. 1, 5TH FLOOR, 10:30 A. M.

4. *Economical Supply of Electric Power for the Industries and the Railroads of the Northeast Atlantic Seaboard*, A Symposium.

Thursday Afternoon, February 19

Parallel Sessions:

AUDITORIUM, 2:30 P.M.

5. *Printing Telegraph Systems*, by J. H. Bell, Telegraph Engineer, Western Electric Co.
6. *Maximum Output Networks for Telephone Substation and Repeater Circuits*, by G. A. Campbell, Research Engineer, American Telephone and Telegraph Co., and Ronald M. Foster, Assistant to Research Engineer, American Telephone and Telegraph Co.

ROOM NO. 1, 5TH FLOOR, 2:30 P.M.

7. *A Method of Separating No-Load Losses in Electrical Machinery*, By C. J. Fechheimer, Designing Engineer, Westinghouse Electric & Mfg. Co.
8. *Inherent Regulation of D-C. Circuits*, by A. L. Ellis, Thomson Laboratory, General Electric Co. and B. W. St. Clair, Standardizing Laboratories, G. E. Co., Lynn, Mass.
9. *Measurements of Projectile Velocities*, by P. E. Klopsteg, Physicist, Leeds & Northrup Co., and A. L. Loomis, formerly Major Ordnance Dept., U. S. A.

Thursday Evening, February 19

Hotel Astor, 7:00 p.m.

Dinner Dance at Hotel Astor. For details see item *Entertainment* following.

Friday Morning, February 20

Room 1, 5th Floor, 10:30 a.m.

10. *A new Form of Vibration Galvanometer*, by P. G. Agnew, Secretary American Engineering Standards Committee.
11. *Precision Galvanometer for Measuring Thermo E. M. Fs.* T. R. Harrison and P. D. Foote, both of U. S. Bureau of Standards.
12. *Notes on Synchronous Commutators*, by J. B. Whitehead, Professor of Electrical Engineering, Johns Hopkins University, and T. Isshiki, Engineer, Shibaura Engineering Works.

Friday Afternoon, February 20

Room No. 1, 5th Floor, 2:30 p.m.

13. *Oscillographs and Their Tests*, by A. E. Kennelly, Professor of Electrical Engineering, Harvard University, and the Mass. Institute of Technology; R. N. Hunter, Engineering Department, American Telephone and Telegraph Co., and A. A. Prior, Instructor Case School of Applied Science.
14. *The Accuracy of Commercial Measurements*, by H. B. Brooks, Physicist, U. S. Bureau of Standards.

ENTERTAINMENT

Dinner—Dance

A Dinner-Dance will be held at the Hotel Astor, Broadway and 44th Street, New York, Thursday evening, February 19, 1920, at 7:00 o'clock. The purpose of the dinner-dance is to provide a pleasant social function for the entertainment of the members and their guests in attendance at the convention.

The dinner will be served at 7:00 o'clock and prompt attendance is desired in order that the Entertainment Committee's arrangements may be carried out as planned.

The subscription price is $5.50 per person.

The tables will accommodate eight or ten persons each. Members are requested to make up their own tables and to state their seating preference to the committee. Communications should be addressed to the Committee on Entertainment, A. I. E. E., 33 West 39th Street, New York.

Inspection Trips

The following companies have courteously offered to open their plants for inspection by members and guests, either individually or in groups, on dates and at hours indicated. The A. I. E. E. convention badge will be accepted as sufficient identification for direct admission to plants or for the issuance of passes where such are required. Directions for reaching plants can be obtained at registration booth.

Wednesday, February 18th, from 2 p.m. to 5 p.m.

American Telephone and Telegraph Company.—Research Laboratories of the Bell System at Western Electric Company's building, 463 West Street. Conveyances will be provided to the laboratories leaving Engineering Societies Building at 2 p.m. Chemical Transmission, Physical, Circuit, Radio Design, Research, Automatic, and Printing Telegraph Laboratories.

Thursday, February 19th, 9 a.m. to 4 p.m.

New York Edison Company.—Waterside Power Stations, East 38th-40th Streets and First Avenue; Substation, 115-117 West 39th Street.

Wednesday, Thursday and Friday, February 18, 19 and 20th.

9 a.m. to 4 p.m.

Brooklyn Edison Company.—Gold Street Station, foot of Gold Street, Brooklyn.

10 a.m. to 4 p.m.

Brooklyn Rapid Transit Company.—Station at Kent and Divison Avenues, Brooklyn.

9 a.m. to 5 p.m.

United Electric Light and Power Company.—Power Station at 201st Street and Harlem River; West Farms Substation.

9 a.m. to 5 p.m.

Public Service Electric Company.—Essex Power Station, Newark, N. J.

10 a.m. to 4 p.m.

New York Central Railroad.—Port Morris Power Station, 143rd Street and Southern Boulevard, New York.

10 a.m. to 4 p.m.

Interborough Rapid Transit Company.—59th Street Power Station, 600 West 59th St., New York; 74th St. Power Station, 74th St. and East River, New York; Substation No. 42, 57th St. and 3rd Ave., New York.

FUTURE A. I. E. E. MEETINGS

March 12, 1920, Pittsburgh. Meeting under auspices of Traction and Transportation Committee. Subject: Electric Traction. Papers will be presented on "The Design of the Chicago, Milwaukee & St. Paul Locomotives," "Short-Circuit Protection for D-C. Substations," and "Automatic Substations."

April 9, 1920, Boston. Joint Meeting with the American Electrochemical Society. Meeting under auspices of Committee on Electrochemistry and Electrometallurgy.

May 21, 1920, New York. Annual business meeting of the Institute.

June 22 to 25, 1920. Annual Convention.

FUTURE SECTION MEETINGS

Milwaukee.—May 19, 1920. Engineers Society of Milwaukee under auspices of the Electrical Section. Speaker: Professor V. Karapetoff. Subject: "The Coming Science of Acoustical Engineering."

Schenectady.—February 6, 1920. Mr. Calvert Townley, President, A. I. E. E., will address the Section.

February 20, 1920. Paper: "Railway Electrification," to be read by Mr. A. H. Armstrong.

Washington, D. C.—February 10, 1920. Subject: "Electric Propulsion of Ships." Speaker: Mr. A. B. Cheyney, Navy Department.

March 9, 1920. Subject: "Electrolysis." Speaker: Mr. B. McCollum, Bureau of Standards.

March 19, 1920. Joint meeting with Illuminating Engineering Society. Subjects: "Development of the R. L. M. Standards for Industrial Lighting" and "Residence Lighting." Speakers: Messrs. W. Harrison, National Lamp Works, and M. Luckiesh, Nela Research Laboratory.

April 13, 1920. Subject: "Transmission Line Problems." Speaker: Mr. Harold Goodwin, Jr., G. E. Co.

FEBRUARY MEETING OF THE A. I. M. E.

The American Institute of Mining and Metallurgical Engineers will hold a meeting in New York February 16th to 19th, 1920, and extends an invitation to the members of the A. I. E. E. to attend any or all of the sessions. The topics to be discussed are as follows:

Monday	10 a. m.	Oil.
	2 p. m.	Oil.
Tuesday	10 a. m.	Oil.
	2 p. m.	Oil.
Monday	2 p. m.	Coal.
Tuesday	10 a. m.	Geology and Mining.
Tuesday	2 p. m.	Mining and Milling.
Wednesday	10 a. m.	Non-Ferrous Metals.
Wednesday	10 a. m.	Iron and Steel. (Manufacture)
Wednesday	2 p. m.	Alloy Steels. (Physical properties)
Wednesday	2 p. m.	Iron and Steel. (Physical properties)

A large number of papers under these general headings will be presented and discussed. The meeting will conclude with an excursion on Thursday.

INSTITUTE MEETING IN CHICAGO

The 357th meeting of the American Institute of Electrical Engineers was held in Chicago, January 9th and 10th, 1920, under the auspicies of the Chicago Section. Technical sessions were held in the afternoon at the headquarters of the Western Society of Engineers and in the evening at the City Club. The attendance at the afternoon session was about two hundred and at the evening session about three hundred.

The Board of Directors of the Institute held a meeting on Friday morning, January 9th, at the rooms of the Western Society of Engineers, Chicago. Present: Vice-President C. E. Skinner, Pittsburgh; Managers, Charles S. Ruffner, Wm. A. Del Mar, New York, Charles Robbins, Pittsburgh, E. H. Martindale, Cleveland, F. F. Fowle, Chicago; Secretary F. L. Hutchinson, New York.

Reference to the important matters discussed at this meeting may be found in this and future issues of the JOURNAL under suitable headings.

The afternoon technical session was called to order by Mr. A. F. Riggs, Chairman of the Chicago Section, who after a few words of welcome turned the meeting over to Vice-President C. E. Skinner who presided in the absence of President Townley.

Mr. Skinner spoke briefly of the success of the policy of having National Meetings from time to time, away from New York Headquarters, many of which meetings have been more largely attended than some of the regular meetings in New York, and also called attention to the fact that the present meeting was a joint meeting of the Chicago Section of the Illuminating Engineering Society, the Electrical Section of the Western Society of Engineers and the A. I. E. E. He then called upon Mr. Cravath, Chairman of the local committee on arrangements, and Chairman of the Electrical Section of the W. S. E. who opened the meeting.

Mr. Cravath called for the first paper of the meeting entitled "The Series System of Street Lighting Distribution," by W. B. Hurley, and in the absence of Mr. Hurley, the paper was read by Mr. Edgar Switzer. Following the presentation of the paper, the discussion occurred, which was participated in by A. E. Bettis, F. F. Fowle, F. A. Vaughn, W. F. Parker, E. N. Lake, Mr. Cameron, C. H. Shepard, W. A. Del Mar, Mr. Nixon and Mr. Switzer.

The Chairman called for the next paper which was entitled, "Multiple Systems of Distribution for Street Lighting," which was presented by the author, Ward Harrison, and the discussion followed, by N. B. Hinson, I. M. Humiston, Mr. Shepard, Mr. Vaughn, H. Goodwin, Jr., Mr. Peaslee, Mr. Cameron and Mr. Harris.

An informal dinner was held in the City Club at 7.30, following which, a paper was presented by Doctor C. P. Steinmetz, on "Constant Potential, Series Distribution for Street Lighting." A discussion followed by C. E. Clewell, (by letter), J. R. Cravath, Mr. Vaughn, Henry Nixson, Mr. Roper and Mr. Harris. An interesting feature in the discussion was the exhibit of a large number of lantern slides by Mr. F. A. Vaughn, illustrating recent Street Lighting Development in Milwaukee.

On Saturday morning, January 10th, an inspection trip was made by seventy members and guests, to a recently completed Street Lighting Sub-station of the City of Chicago on the Northwest Station of the Commonwealth Edison Company. Transportation was provided by special cars of the Chicago Surface Lines.

ECONOMICAL SUPPLY OF ELECTRIC POWER

FOR THE INDUSTRIES AND RAILROADS OF THE EAST ATLANTIC SEABOARD

The above title forms the general subject of a symposium which has been scheduled for the Midwinter Convention session on Thursday morning, February 19th. The specific subjects to be presented and the contributors to the symposium are as follows:

Large Steam Turbines. Messrs. W. L. R. Emmet and Francis Hodgkinson.

Large A-C. Generators. Messrs. H. G. Reist and F. D. Newbury.

Heavy Traction Locomotives. Messrs. William B. Potter, N. W. Storer and B. G. Lamme.

Transmission and Distribution. Messrs. L. C. Nicholson, Arthur E. Silver and Percy H. Thomas.

The subject of economical power in the region of the Atlantic Seaboard is closely allied to the proposed super-power project discussed by Mr. W. S. Murray in the January JOURNAL. The following extracts from a letter addressed to the above contributors to the symposium, by Mr. Murray, chairman of the Traction and Transportation Committee gives a general idea of the broad engineering features to be considered:

It has been said that the clash of rival systems has delayed the electrification of railroads. This, in my opinion, is true; but I question whether such a result, after all, has not been beneficial

Fifteen years has been the period over which we have had opportunity to analyze the theory and practise of railway electrification.

Had we known fifteen years ago what we know today about electrification, and therefore could have decided the proper system to apply to each case, the financial stress under which the railroads were laboring would have prevented electrification.

Today the industrial demand for power has grown so prodigiously that faced with the old methods of power production which we have been perpetuating, we find ourselves faced with two factors, greatly militating against securing and maintaining supremacy in world's trade. Viz.: (1) throttled production, and (2) waste of the nation's natural resources.

The past fifteen years of education have opened the eyes of the "opposing camps" to certain fundamental factors which will now permit a prompt unanimity of opinion regarding what system applies. The railroad managers have in the past justly taken the ground that since we could not make up our minds which system was correct, they would wait until we could. But, as stated before, I believe that finance and not system has been the real cause of lack of action on the part of the railroads to electrify and that the delay has been truly beneficial since we can now stand on more solid ground for decision.

I am enclosing copy of an address made before the Connecticut Chamber of Commerce, November 19th, 1919.

While the super-power line as described in that address is an important adjunct to the plan proposed, the central idea is the indorsement of central station expansion through means of which national production may be increased and the conservation of our natural resources made secure.

As the major demand for power in the territory between Boston and Washington is for industrial purposes, I believe that I will be supported in the following conclusion:

(a) That prime generating machinery should be three-phase.

(b) That the power to be applied to railroads should be through synchronous motor generators with the synchronous motor fields designed

to relieve to a maximum degree the direct current excitation of the prime generating machinery.

(c) That the question of whether train propulsion be by direct or by alternating current should be settled purely upon the economic relations existing between the generating side of the motor-generator substations and the driving wheels of the motive power. In saying this I realize that this robs the single-phase system of the argument to which it has justly laid claim by virtue of the higher efficiency of static versus rotative substations.

Railroad electrifications, in the past, have been individual to themselves. Today I believe that you will agree that they will form only a part of a whole and indeed be a smaller part, the industrial load being the greater—both receiving power from the same source.

I would like to be first under the above conditions in recognizing two serious limitations to single-phase generation.

(a) Size of generators.

(b) Low power-factor regulation.

The Paper's Committee have assigned the 18th of February during the Midwinter Convention in New York as the date for the presentation of a composite paper bearing upon the subject as presented in the accompanying pamphlet.

It is respectfully requested that you, as expert authorities in the design and application of the apparatus in your respective fields, keeping in mind the central idea of zone application of power, contribute your ideas, and while doing so, eliminate all thought of the past battle of systems.

I further believe that you will agree that the hour has struck for a united front and that such a paper will help the advance of electricity's rightful use in the industrial and railway field.

ENGINEERING FOUNDATION

REPORT OF PROGRESS

A PROGRESS Report of the Engineering Foundation to United Engineering Society, copy of October, 1919, offers to the members of the society an interesting and comprehensive review of the history and accomplishments of the Engineering Foundation, embracing also a survey of the United Engineering Society. In 1914 a sum of money was presented to the Society as a trust fund, the interest of which was to be used in the promotion of engineering research. This resulted in the Engineering Foundation, and the Engineering Foundation Board, for the administration of the income. The opportunities and obligations of this Board are emphasized in the Report; it is "in effect the trustee in these matters for the whole body of American engineers. It is their instrumentality for the stimulation, direction and support of research. It is, furthermore, the liaison agency between engineers on one hand and other technologists and scientists on the other hand, in activities concerned with research in all branches of the mathematical, physical and biological sciences."

Mr. Ambrose Swasey, the founder of the institution, is a man who has long entertained a desire to exalt the work of the engineer and to add to the accumulated facts which serve to guide him in his undertakings. He was born at Exeter, New Hampshire, in 1846. At eighteen he began to learn the machinist's trade; at twenty-three, with Worcester Reed Warner, he went to the Pratt & Whitney Company, Hartford, Connecticut. In 1880 the two removed to Cleveland, Ohio, and established the business in which their names have since been linked—the manufacture of various precision instruments. But Mr. Swasey is not only an engineer and manufacturer, he is also a traveler and philanthropist. He has journeyed widely, twice circling the earth; and has presented many public gifts other than the endowment funds for the Engineering Foundation. He is a member and has held office in a number of engineering societies; has been granted several degrees; and was made a Chevalier of the Legion of Honor by the French Republic. Mr. Swasey first gave the United Engineering Society two hundred thousand dollars as the nucleus of an endowment, the income of which was to be used "for the furtherance of research in science and engineering, or for the advancement in any other manner of the profession of engineering and the good of mankind." Four years later, in 1918, he added one hundred thousand dollars to the fund, making the present total three hundred thousand dollars.

April 15, 1915, the Engineering Foundation Board held its organizing meeting; and in October, 1916, United Engineering Society provided an office for the Foundation in Engineering Societies Building. The Board, charged with the responsibility of administering the funds, safeguards its expenditures in every way. It supports no project, the merits of which have not been demonstrated by competent inquiry. In the development of such inquiry, it has the co-operation of the National Research Council, an organization of American scientists, engineers and educators, established in April, 1916, which has world-wide scientific affiliations. For a considerable time the Foundation contributed its full strength to the support of this Council in its formative period.

Some of the work accomplished by the Engineering Foundation follows: When the nation was at war, it conducted tests in co-operation with the Committee on Submarine Detection, to determine the value of a veil of spray in reducing the visibility of ships at sea, with results which have been formally reported. It conducted a careful inquiry concerning the practicability and advisability of establishing a hydraulic station for testing large water wheels. It formulated a proposal to the several Founder Societies to undertake a study of engineering society organization for the purpose of developing a possible procedure or series of procedures of such evident merit that they would appeal to those who are likely to be most interested.

The Foundation is now conducting investigations on the following: Wear of gears; directive control of wireless communication; weirs for measurement of water; and mental hygiene of industry. It is moreover assisting the Division of Engineering, National Research Council, in a series of preliminary investigations concerning the desirability of researches along several different specific fields of activity; and is co-operating with the University of Illinois in researches on the Fatigue Phenomena of Metals.

Members who are interested may obtain copies of the Report upon application to F. L. Hutchinson, Secretary A. I. E. E.

INTERNATIONAL ELECTROTECHNICAL COMMISSION

FOURTH PLENARY MEETING IN LONDON

The fourth plenary meeting of the I. E. C. was held at the Institution of Civil Engineers, London, October 20-22, 1919. Over 50 delegates representing 19 countries were received by the president, Maurice Leblanc at the opening meeting in the afternoon of October 20. The delegates were welcomed by Sir Richard Glazebrook, C.B., president of the British National Committee, Mr. Roger T. Smith, president of the Institution of Electrical Engineers, and Mr. Everest on behalf of the British Electrical and Allied Manufacturers' Association.

The program of sessions was as follows:

Monday, Oct. 20, at 3:00 p.m., official opening and address of welcome.

Tuesday, Oct. 21, at 10 a.m. and at 3.00 p.m., working sessions of the whole Commission to consider future work of advisory committees and draw up resolutions to present at the plenary meeting.

Wednesday, Oct. 22, at 11:00 a.m., plenary meeting to ratify resolutions.

Wednesday, Oct. 22, at 3.00 p.m., Council meeting.

A Banquet was given by the British National Committee, Council of the Institution of Electrical Engineers, and the Council of the British Electrical and Allied Manufacturers'

Association to the foreign Delegates, on Tuesday evening, at which an address was delivered by the Rt. Hon. A. J. Balfour, O.M.

The working sessions, over which Sir Richard Glazebrook, C.B., was elected to preside, discussed a number of subjects on which definite proposals were formulated for submission to the plenary meeting.

At the plenary meeting advisory committees were appointed or reappointed as follows:

Nomenclature. The Committee was re-appointed and will confine its attention to deleting those terms and definitions which are unacceptable and has power to instruct the Central Office to issue the remaining terms and definitions without reference to a plenary meeting.

Rating of Electrical Machinery. The Committee was re-appointed.

The Plenary Meeting ratified the rules agreed to at the last meeting, together with the modifications and additions proposed at the meetings of the advisory committee held in Paris in May, 1919, and in London in October, 1919.

The Editing Committee and the General Secretary are authorized to edit these decisions which will be published without delay.

Symbols. The Committee was re-appointed to consider Publication 27 issued in 1914. The Committee has power to instruct the Central Office to issue the Publication with desired modifications, without further reference to a plenary meeting.

Prime Movers for Electrical Plant. The Committee was re-appointed to continue the important work which it has so far been engaged upon.

Aluminum. A Committee was appointed to study the question of the adoption of an International standard of resistance for aluminum.

The line adopted for the preparation of the standard of resistance for Copper Publication 28 is to be closely followed. The Directors of the National Physical Laboratories including Prof. Paul Janet of Paris will be invited to collaborate.

Screw Lamp Caps and Lamp Holders. A Committee was appointed to study this question which will confine its report to matters of international interchangeability, questions of material not being dealt with.

Charging Plugs for Electrical Vehicles. A Committee was appointed to study the question of international interchangeability only. It is understood that the charging plugs used in the United States and Great Britain are identical.

Standard Pressures for Distribution and Insulators. A Committee was appointed to study the question of standard pressures for insulators and subsequently make a comparative study of high tension distribution pressures. The Committee will work in close conjunction with the Committee on Rating.

It was decided to hold Meetings of the Advisory Committees in Brussels in the early Spring of 1920, the Central Office being empowered to make the necessary arrangements for these Meetings.

At the Council Meeting held on Wednesday, October 22nd., Dr. Mailloux, President of the U. S. National Committee, was unanimously elected as the new President of the I. E. C. Dr. Mailloux was one of the founders of the Commission, and its success has been due in no small measure to his efforts on its behalf. His great linguistic abilities have been of the utmost service on many occasions.

In view of the general rise in prices it was agreed that each Committee should be asked to double its subscriptions.

The Council accepted the invitation of the U. S. National Committee to hold the next Plenary Meeting in the United States of America during the summer of 1920.

At the close of the Meeting Dr. Mailloux, on behalf of all his friends, presented a silver cup to Col. R. E. Crompton, the Honorary Secretary of the Commission.

ANALYSIS OF WORK ACCOMPLISHED

So far as relates to the subject of Rating of Electrical Machinery, the work accomplished falls into two categories. In the first category is the work which was ratified on October 22nd, the last day of the plenary meeting. In the second category is further work done by the Advisory Committee on Rating of Electrical Machinery which continued in session for three more days. The work in this second category will be brought together as a recommendation of the Advisory Committee, and will not, until ratified at a plenary meeting, have the status of I. E. C. Rules. Even the portion ratified at the plenary meeting was in the form of notes from which the Editing Committee of the I. E. C. was authorized to prepare the official report. This report will be the one submitted to the various National Committees for study.

Consequently, at the present time, any statement of the things done must be made with reservations. It does not seem worth while to attempt to distinguish between the different degrees of completeness of the work done. The best that can be done is to state the general trend of matters.

I. For the purposes of the I. E. C. Standards, electrical machinery is, for the present divided into two groups.

In the first group fall:

1. Rotating machines of which the terminal pressures do not exceed 5000 volts, or of which the rated output does not exceed 750 kv-a., or of which the stator cores do not exceed 50 cm. in length, measured axially.
2. All transformers which are not water-cooled.

II. For machines in this group, there are recognized only two methods of temperature measurement for acceptance tests, namely:

1. Resistance and thermometer, which ever gives the highest.
2. Thermometer measurements.

III. For machines whose terminal pressures exceed 5000 volts or of which the rated output exceeds 750 kv-a., or of which the stator cores have an axial length greater than 50 cm., a third method of temperature measurement, namely by embedded temperature detectors was recognized, by the Advisory Committee on Rating. This has, at present, no more status than that of being the recommendation of that Committee.

IV. The alternative of permitting thermometer measurements alone with a five-degree penalty, practically as customary in America, has been adopted by the Committee on Rating although with certain modifications.

V. Commutators and slip-rings are permitted to have any temperature consistent with successful operation, but if temperature rises of more than 50 degrees are employed for commutators the manufacturer shall give a special guarantee that the temperature obtained shall not impair the commutation.

VI. An Ambient Temperature of Reference of 40 deg. cent. for air was adopted for I. E. C. ratings.

VII. The I. E. C. Committee on Rating purposes to consider the adoption of an ambient temperature of reference for tropical ratings. Amongst the values mentioned informally, considerable stress was laid upon the appropriateness of 55 degrees. If this should ultimately be adopted, it would amount to a 15 degree lower temperature rise for machines with a tropical rating.

VIII. An Ambient temperature of reference of 25 deg. cent. for water was recommended for I. E. C. ratings by the Advisory Committee on Rating.

IX. For water-cooled transformers the Advisory Committee on Rating recommended that the limits for the highest observable temperatures shall be decreased by 10 deg. below those permitted for other machinery. Since the ambient temperature of reference for water is 15 deg. below that for air, this amounts to permitting a 5-degree greater temperature rise for water-cooled transformers than for transformers of other types.

X. The Advisory Committee on Rating recommends a

temperature-limit of 90 deg. cent. for the oil in which transformers are immersed.

XI. The principle of correction back to shut-down is recognized.

XII. The permitted temperature limits for non-impregnated cotton, silk and paper are 15 degrees below the limits for these materials when impregnated.

XIII. The rule for the duration of the temperature test for a machine with a continuous rating is that the test shall be continued until it is evident that the maximum temperature rise attained would not exceed the prescribed limits if the test were to be prolonged until the final steady temperature were attained.

XIV. Very satisfactory progress was made by the Advisory Committee on Rating in its recommendations concerning High Voltage Tests. So far as the matter was carried, the Rules recommended are in quite good agreement with those already adopted in several countries, including America.

ENGINEERING COUNCIL

Headquarters: 29 West 39th Street, New York

Organized by several national engineering societies, including the Institute, to represent their membership in matters of common interest, especially relationships of engineers to the public and to governments. Council is one result of a wide movement to enlarge the activities of engineers for patriotic, social and personal welfare.

CLASSIFICATION OF ENGINEERS

A COMPLETE and definite classification for engineers in Federal, State, County, Municipal and Railroad service was approved by Engineering Council at its meeting on December 18th, 1919, when it adopted the classification proposed in the third progress report of its Committee on Classification and Compensation of Engineers, of which Arthur S. Tuttle, Member, Am. Soc. C. E., is chairman. Eight grades are defined, five professional and three sub-professional, and the necessary qualifications are specified. A striking comparison of the results of this latest investigation into Federal, State and Municipal service with those reported in 1917 by the committee of the American Society of Civil Engineers appointed to investigate the conditions of employment and compensation of civil engineers was pointed out in the committee report.

The extracts of this report which follow include, in addition to the classification and the above-mentioned comparison, an interesting tabulation of average salaries in Federal, State and Municipal service, with average ages of the incumbents and average salaries recommended by the engineers in charge. The Committee asked for an appropriation of $10,000 for the purpose of continuing the investigation into present salaries and to insure publicity and progress in the effort to raise the level of engineering compensation. This is one of the items for which Engineering Council is making its appeal for funds.

Findings and Conclusions of the Committee

The investigations have shown the lack of any adequate or consistent employment policy with respect to professional engineers. This is evidenced by the following conditions which are believed to be largely responsible for the unsatisfactory status of men engaged in this class of work:

1. Absence of any uniform system of grading of positions.
2. Lack of uniformity in titles of positions with respect to duties.
3. Inequalities in compensation for positions of the same grade.
4. Generally inadequate compensation for services rendered.

To the end that these conditions may be corrected and proper and equitable conditions of employment established, the following principles and practises are recommended by the Committee, though not yet acted upon by Council.

1. Positions should be classified in accordance with the type of work, and with the character of the duties to be performed and the qualifications necessary for their performance, as indicated by a system of grading.
2. Within the salary limits fixed for each grade, there should be a system of advancement through the grade based upon experience gained in the position and upon proof of increase in the proficiency of the employee in performing the duties of the grade.
3. Promotions from grade to grade should depend upon the existence of a vacancy in the higher grade and proof that the employee is qualified to fill the vacancy.
4. The determination of salary adequate to procure for and retain in engineering work a high class of employees, should take into account and properly weigh the following considerations:
   (a) The capital invested, both in money and in time, in obtaining the requisite fundamental training.
   (b) The amount and character of experience and the degree of personal ability required.
   (c) The relative value of the classes of work to be performed.
   (d) The amount paid for similar service in other lines of work.
   (e) The amount necessary to enable the employee to maintain a standard of living commensurate with the general standards of the community for positions of similar dignity and responsibility.
5. In the interest of an adequate social policy, no position likely to be occupied by individuals of an age to assume family responsibilities should fail to pay an amount sufficient to permit the maintenance of the average family in reasonable decency and comfort.
6. In the interest of the employees as a whole and of the employer, a system should be established by which employees who fail to maintain satisfactory standards of service should be removed, transferred, demoted, or retired as may be equitable in the circumstances.

Classification of Engineering Positions in Federal, State, County, Municipal and Railroad Services

The grades proposed, which appear to be well adapted to use not only in all of the services represented but also for all other forms of engineering activities, have been divided into two classes, the Professional Service being deemed to include men who have received an engineering degree from an educational institution of recognized standing or who have obtained similar qualifications through practise of the profession and by mastering the fundamentals of engineering science, while the Sub-Professional Service includes assistants with at least a high school education, who enter upon the practise of the profession in the performance of responsible duties for which an

engineering training is not essential, but who through experience and study may fit themselves for the higher grades. The classification is as follows:

PROFESSIONAL SERVICE

Grade 1.—Chief Engineer

Duties. To act in chief administrative charge of a technical organization, or of a main division thereof; to determine the general policies of the organization under the limitations imposed by law, regulation, or other fixed requirement; to have final responsibility for the preparation of reports, cost estimates, designs, and specifications and for the construction, maintenance, or operation of engineering works or projects; to have full charge of the collection and presentation of data for and the conduct of valuation proceedings; to conduct or direct the most comprehensive lines of engineering research.

Qualifications. Training and experience of a character to give substantial evidence of engineering knowledge and ability or of executive capacity of highest order along lines of work similar to those involved in the position to be occupied and of at least twelve years' duration, of which at least four years shall have been spent in duties of Engineer or their equivalent and at least five years in responsible charge of important work or projects. Fundamental training equivalent to that represented by professional degree granted upon the completion of a standard course of engineering instruction in an educational institution of recognized standing or, in absence of such degree, at least four years of additional experience. The completion of each full year of such standard course shall be considered the equivalent of one year of such additional experience.

Grade 2.—Engineer

Duties. Under general administrative direction and within the limits of the general policies of the organization, to have responsible charge of and to initiate and determine policies for a major subdivision of an organization; to prepare for final executive action reports, cost estimates, designs, specifications, and valuation studies and data; to have immediate charge of the construction, maintenance, or operation of engineering works or projects of major importance; to conduct or direct major lines of engineering research; or to furnish for executive action expert or critical advice on engineering works, projects or policies.

Qualifications. Active professional practise or executive charge of work for at least eight years, of a character to demonstrate a high degree of initiative and of ability in the administration, design, or construction of engineering work or projects of major importance, of which at least three years shall have been spent in duties of Senior Assistant Engineer, or their equivalent, and at least three years in responsible charge of work. Fundamental training equivalent to that represented by professional degree granted upon the completion of a standard course of engineering instruction in an educational institution of recognized standing or, in absence of such degree, at least four years of additional experience. The completion of each full year of such standard course shall be considered the equivalent of one year of such additional experience.

Grade 3.—Senior Assistant Engineer

Duties. Under general administrative and technical direction, to be in responsible charge of an intermediate division of an organization; to exercise independent engineering judgment and assume responsibility in studies and computations necessary for the preparation of reports, cost estimates, designs, specifications, or valuations; to have immediate charge of the construction, maintenance, or operation of important engineering works or projects; or to conduct or direct important lines of engineering research.

Qualifications. Active professional practise or executive charge of work for at least five years, of which at least three years shall have been spent in duties of Assistant Engineer, or their equivalent, with at least one year in responsible charge of work. Fundamental training equivalent to that represented by professional degree granted upon the completion of a standard course of engineering instruction in an educational institution of recognized standing or, in absence of such degree, at least four years of additional experience. The completion of each full year of such standard course shall be considered the equivalent of one year of such additional experience.

Grade 4.—Assistant Engineer

Duties. Under specific administrative and technical direction, to be responsible for the conduct of the work of a minor subdivision of an organization; to collect and compile data for specific items of engineering studies; to take immediate charge of field survey projects and of the design and construction of minor engineering work; to lay out and develop work from specifications and to supervise the work of a drafting or computing force; or to conduct specific tests or investigations of apparatus, material, or processes.

Qualifications. Experience for at least two years in duties of Junior Assistant Engineer or their equivalent. Fundamental training equivalent to that represented by professional degree granted upon the completion of a standard course of engineering instruction in an educational institution of recognized standing, or, in absence of such degree, at least four years of additional experience. The completion of each full year of such standard course shall be considered the equivalent of one year of such additional experience.

Grade 5.—Junior Assistant Engineer

Duties. Under immediate supervision, to perform work involving the use of surveying, measuring, and drafting instruments; to take charge of parties on survey or construction work; to design details from sketches or specifications; to compute and compile data for reports or records; to inspect or investigate minor details of engineering work; or to perform routine rests of apparatus, material, or processes.

Qualifications. No experience required other than that involved in securing a professional degree upon the completion of a standard course of engineering instruction in an educational institution of recognized standing; but in absence of such degree, a high school education or its equivalent is required and at least four years' experience in the use of surveying, measuring or drafting instruments, or the computation and compilation of engineering data, together with evidence of a knowledge of the fundamentals of engineering science sufficient, with further experience, to qualify for the higher professional grades. The completion of each full year of such standard course of engineering instruction shall be considered as the equivalent of one year of experience.

SUB-PROFESSIONAL SERVICE

Grade 6.—Senior Aid, Office

Duties. To supervise the plotting of notes and maps, and to direct the work of a drafting or computing squad.

Qualifications. Experience for at least five years in tracing, lettering, drafting, and computing, of which at least three years shall have been spent in the duties of draftsman. Education equivalent to graduation from high school. The completion of each full year of a standard course of engineering instruction in an educational institution of recognized standing shall be considered as the equivalent of the experience otherwise required, with the provision, however, that at least one year shall have been spent in the duties of draftsman.

Grade 6.—Senior Aid, Field

Duties. To direct work of field party on surveys or construction; to keep survey notes and engineering records; to

supervise construction or repair work; to direct the work of computing surveys and estimates; to direct the work of making minor engineering computations.

Qualifications. Experience for at least five years in the use and care of surveying instruments, of which at least three years shall have been spent in the duties of instrumentman. Education equivalent to graduation from high school. The completion of each full year of a standard course of engineering instruction in an educational institution of recognized standing shall be considered as the equivalent of the experience otherwise required, with the provision, however, that at least one year shall have been spent in the duties of instrumentman.

Grade 7.—Aid, Office

Duties. To prepare general working drawings where design is furnished; to plot notes and prepare maps; to design simple structures; to make computations and compile data for reports and records; to check plans, surveys, and other engineering data.

Qualifications. Experience for at least two years in tracing, lettering, drafting, and computing. Education equivalent to graduation from high school and familiarity with the use of the slide rule, and of logarithmic and other simple mathematical tables. The completion of each full year of a standard course of engineering instruction in an educational institution of recognized standing shall be considered as the equivalent of the experience otherwise required.

Grade 7.—Aid, Field

Duties. To run surveying instruments and to adjust and care for same; to compute surveys and estimates; to make minor engineering computations; to inspect incidentally construction or repair work.

Qualifications. Experience for at least two years in the duties of rodman. Education equivalent to graduation from high school and familiarity with the construction, operation, and care of surveying instruments. The completion of each full year of a standard course of engineering instruction in an educational institution of recognized standing shall be considered as the equivalent of the experience otherwise required.

Grade 8.—Junior Aid, Office

Duties. To trace and letter maps and plans; to make simple drawings from sketches and data; to make minor calculations.

Qualifications. Education equivalent to graduation from high school.

Grade 8.—Junior Aid, Office

Duties. To run tape or levelling rod; to perform other miscellaneous subordinate duties in survey party in field or office, as directed.

Qualifications. Education equivalent to graduation from high school.

Experience Equivalents for Post-Graduate Work

The completion of each full year of post-graduate work in the specific subject of study or investigation appropriate to a particular service or branch of service shall be considered the equivalent of one and one-half years of general experience, but such substitution shall not thus be made for more than four years of such experience or be considered as reducing the requirements in any grade of the number of years engaged in the conduct or direction of responsible work.

An examination of the schedule shows that the minimum experience requirements for the various grades may be briefly summarized as follows:

Service	Grade	Experience in Years With Degree in Engineering	Experience in Years Without Degree in Engineering
Sub-professional	8—Junior Aid	0	0
	7—Aid	0	2
	6—Senior Aid	0	5
Professional	5—Junior Assistant Engineer	0	4
	4—Assistant Engineer	2	6
	3—Senior Assistant Engineer	5	9
	2—Engineer	8	12
	1—Chief Engineer	12	16

The following table illustrates the practicability of adapting the proposed classification to any particular grade or branch of the engineering service and in such a way as to clearly retain a description of the relative rank.

PROFESSIONAL SERVICE

1.—Chief Engineer

Chief Engineer	Deputy Chief Engineer
State Engineer	Deputy State Engineer
City Engineer	Deputy City Engineer
Chief Engineer of Maintenance of Way	Director, etc.

2—Engineer

Electrical Engineer	Division Engineer
Mechanical Engineer	District Engineer
Mining Engineer	Sewer Engineer
Chemical Engineer	Topographical Engineer
Bridge Engineer	Landscape Engineer
Sanitary Engineer	Hydraulic Engineer
Tunnel Engineer	Geodetic Engineer
Maintenance of Way	Engineer Structural Engineer
Signal Engineer	Valuation Engineer
Highway Engineer	Designing Engineer, etc.

3—Senior Assistant Engineer

Senior Assistant Electrical Engineer
Senior Assistant Mechanical Engineer
Senior Assistant Mining Engineer
Senior Assistant Chemical Engineer
Senior Assistant Bridge Engineer, etc.

4—Assistant Engineer

Similar to Senior Assistant Engineer

5—Junior Assistant Engineer

Engineer Inspector, etc.

SUB-PROFESSIONAL SERVICE

6—Senior Aid

Office: Chief Draftsman	Field: Chief Instrumentman
Chief Computer	Chief Inspector

7—Aid

Office: Draftsman	Field: Instrumentman
Computer	Inspector

8—Junior Aid

Office: Junior Draftsman	Field: Rodman
Tracer	Tapeman

Striking Comparison of Results of Investigations Into Compensation

In 1913 a committee was appointed by the Board of Direction of the American Society of Civil Engineers to investigate the conditions of employment and compensation of civil engineers. This committee was headed by the late Alfred Noble, who was succeeded as chairman by Nelson P. Lewis. In its final report, presented at the annual meeting of the Society held in 1917, the committee gave the results of its canvasses, com-

prising returns from 6378 engineers, of whom 1319 were non-members. The distribution among the various services of such returns as could be classified showed an average compensation as follows:

Service	Number of Classified Men	Average Compensation
States and Counties	387	$2,735
National Governments	575	2,899
Municipalities	764	2,994
Technical Schools	262	3,240
Railroads	814	3,325
Private Companies	2,198	4,240
Consulting Engineers	620	6,737
Contractors	165	7,678
	5,785	$4,032

The committee advised that the analysis of the returns showed that the pay received by members of the Society was generally about 25 per cent above that of non-members. It also stated that an effort had been made to obtain information from Railroad, Municipal, State, and Federal Departments but that the officials in authority considered it impracticable to undertake a collection of the desired data, and in the absence of this co-operation no headway could be made. The committee also reported that from the meager information obtained it was "convinced that the compensation for engineering work compares favorably with that received by men of any other profession," and that there was need for "better trained engineers rather than of more engineers."

That a radical change of heart has since taken place on the part of responsible department heads is clearly evidenced by the fact that practically the entire Federal engineering service, except the War Department, has co-operated in the present inquiry, as have also 42 per cent of the state officials, and 70 per cent of the municipal officials, and that the financial status of 10,089 men in these grades has now been revealed as compared with a total of 1726 men, in the same classes of service, who replied to the 1913-1916 inquiry. It also appears that the respondents in the case of the previous investigation were largely confined to the classes receiving maximum compensation, the average rate of present compensation shown by the new return being as follows:

Service	Number of Men	Average Compensation
Federal Government—Navy Department	594	$2,474
Federal Government—(excluding War and Navy Departments)	3,956	1,814
Federal Government—(excluding War Department)	4,550	1,900
State	2,222	1,700
Municipal	3,317	1,820

In comparing these returns with those received by the previous committee, the decrease in the value of the dollar should also be borne in mind.

Results from Questionnaires

Tables 1, 2 and 3 include partial results of the analysis of Federal, State and Municipal returns from questionnaires received up to the date of the committee report, December 15th, 1919.

TABLE I.—FEDERAL SERVICE, SUMMARY OF PRESENT SALARIES BY GRADES.

*Based on such returns as are complete.
†As recommended by the Engineering heads replying to questionnaire.

It is thus disclosed that the average compensation for grades representing 68 per cent of the engineers in the Federal Service, other than the War Department, and 86 per cent of those in State and Municipal Service, is less than is required for the support of a family on a scale sufficient to provide for necessities (assumed at $2200 per annum), to say nothing of the expense of giving children anything like the education with which the breadwinner was equipped.

It would seem reasonable to assume that men in the "Junior Aid" grade have not reached an age which would require compensation sufficient to support a family, but that the salary limitation for men in higher grades should clearly be sufficient to meet this need. On this basis it is safe to state that with anything like suitable compensation, not more than about 25 per cent of the entire service, if properly organized, should receive less than $2200 per annum. The investigation made

by the State and Municipal Section shows that the average age of the present incumbents of the lowest grades is actually about 27 years; if they are to be adequately provided for as permanent employees, the percentage of men to receive less than $2200 is clearly negligible.

A comparison with the pay of the industrial worker who serves under the engineer also bears testimony to the fact that, while admitted by none as to value, the actual compensation for brawn is to-day greater than for engineering brain. The need for setting up some scale of compensation for the engineer to correct this serious condition is, therefore, obvious, as is also that for the inquiry now being carried on by the Committee. Unless a radical improvement can be brought about, it seems evident that the profession cannot attract to or retain in it men of the caliber required to command the respect in which it has heretofore been held by the public, and that so long as they are continuously struggling with the problem of making even a bare living, their efficiency will be minimized and their incentive to work with other than a purely selfish interest will be lacking.

That a serious condition of unrest exists in the Municipal and State services is clearly evidenced by explicit statements in this respect in 44 per cent of the questionnaires returned, while in only 13 of these services were conditions as to morale reported to be satisfactory.

From the investigation made by each of the sections of the Committee, it appears that the heads of sixteen engineering bureaus in the Federal Government (excluding the Navy Department) have recommended an average increase in present compensation averaging about 59 per cent while similar increases in the State and Municipal Services, as recommended by the engineering heads, average 26 per cent.

As a result of the inquiry now in progress under the direction of the Congressional Joint Commission on Reclassification of Salaries, the attention of all members of the Federal Service has been drawn to this question in such a way as to make it

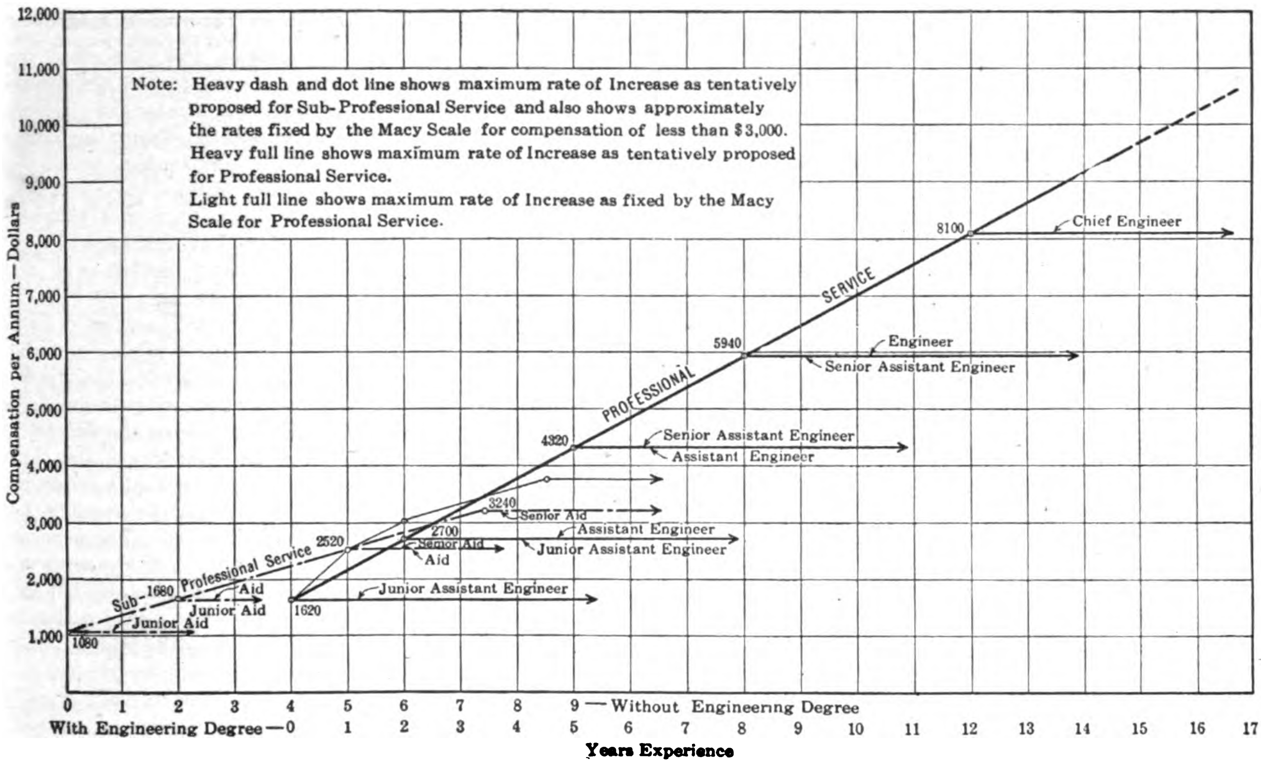

Diagram Showing Maximum Rate of Progress Through the Various Grades as Adopted, and Also Indicating the Compensation Tentatively Proposed for Each Grade

one of close study and analysis, which condition doubtless accounts for the comparatively modest recommendation made by the representatives of the State and Municipal Services, whose reply to our inquiry has been individual and who have doubtless been confronted with the necessity of recognizing relationship to other workers in the same services in whose interests no concerted move of this character has been attempted.

Your Committee is impressed with the method which has been followed by the Federal Section in setting up a standard of compensation based on a readjustment to the new conditions as to cost of living, this being dependent on an award made on October 24, 1918, by the Shipping Wage Adjustment Board, which was designed to provide uniform national wage scale for all shipbuilding workers, including a scale of compensation for draftsmen and copyists. It is also understood that this wage scale, which is generally known as the Macy scale, has since been adapted with modifications to the needs of certain bureaus in the Navy Department. In the accompanying diagram there is illustrated a comparison of the compensation fixed under the Macy Scale with the maximum rates suggested by the Federal Section. A further comparison has also been made with scales proposed by other organizations, which seem to justify the schedule of salaries now suggested by the Committee for discussion, which is as follows:

Grade	Total Years Experience Required to Qualify: With Professional Degree	Without Professional Degree	Salary Range: Minimum	Maximum
8—Junior Aid		0	$1,080	$1,560
7—Aid		2	1,680	2,400
6—Senior Aid		5	2,520	3,240
5—Junior Assistant Engineer	0	4	1,620	2,580
4—Assistant Engineer	2	6	2,700	4,140
3—Senior Assistant Engineer	5	9	4,320	5,760
2—Engineer	8	12	5,940	No limit
1—Chief Engineer	12	16	8,100	No limit

Applying the average proposed salary to the present incumbents of these positions as reported in the State and Municipal Services, it will be found that there would be a resulting increase in annual compensation totalling about $5,500,000 as compared with a total increase of $2,500,000 recommended by the service heads, against which should, however, be charged the economy growing out of the increased efficiency brought about by a restoration of morale.

The Committee is not prepared at this time to recommend the adoption of any definite schedule of compensation, and it is not at all clear as to the wisdom of fixing even a minimum limit on the highest grades of service or of keeping the maximum of one grade below the minimum of the grade above, all of which questions are now receiving its serious consideration, as is also the question concerning the provision to be made for advancing within the limits of a grade, for which a plan is suggested by the Federal Section. Under this plan it is proposed at yearly intervals, through ratings determined by a Personnel Board, to provide for awarding an increase in compensation to three-fourths of the men in a grade receiving less than the maximum compensation of the grade, who through fitness and industry have shown themselves to be of increased value to the service. Those in the highest third of this preferred list would each receive the maximum rate of increase, which under the proposed scale would be $480, while each of the next two-thirds would receive an increase of $240, the latter figure corresponding with what would then be the average increase for all of the men in the grade.

It would seem to the Committee that, pending the completion of the investigation, the scale of compensation herein presented and the plan for promotion within a grade is adapted to general use in all branches of engineering service. The Committee believes, however, that a general discussion of this question is desirable.

The chairmen of the sections of the Committee are as follows:

Classification and Compensation of Engineers

Arthur S. Tuttle, Chairman, Deputy Chief Engineer, Board of Estimate and Apportionment, Municipal Building, New York.

Francis Lee Stuart, Consulting Engineer, 50 East 42nd Street, New York City.

John C. Hoyt, Chief, Division of Water Resources, U. S. Geological Survey, Washington, D. C.

Charles Whiting Baker, Consulting Editor, Engineering News Record, 31 Nassau Street, New York City.

M. O. Leighton, Chairman, National Service Committee of Engineering Council, 502 McLachlen Building, Washington, D. C.

Railroad Section

Francis Lee Stuart, Chairman.

Frank H. Clark, Consulting Engineer, 15 Park Row, New York City.

Bion J. Arnold, Consulting Engineer, 105 So. LaSalle Street, Chicago, Illinois.

State and Municipal Section

Arthur S. Tuttle, Chairman.

M. M. O'Shaughnessy, City Engineer, San Francisco, Cal.

F. W. Cappelen, City Engineer, Minneapolis, Minn.

Federal Section

John C. Hoyt, Chairman

John S. Conway, Asst. Commissioner of Lighthouses, Washington, D. C.

Oscar C. Merrill, Chief Engineer, Forest Service, Washington, D. C.

REGISTRATION OF ENGINEERS

Because of widespread and persistent interest in the subject of licensing or registering engineers, architects and surveyors, Engineering Council, at its meeting of October 25, 1910, authorized the creation of a committee to make a thorough study and submit a report. Fifteen engineers from all parts of our country, and of long experience in the various branches of the profession of engineering were appointed as members of this committee. The committee presented a report to Engineering Council at its meeting December 18, 1919. This report is accompanied by a "Recommended Uniform Registration Law, to regulate the practise of professional engineering, architecture and land surveying." Council voted to receive this report and to give it together with the proposed law, as wide publicity as could be secured in order that discussion might be elicited to guide Council in the consideration of this important matter at its meeting in February 1920. Engineering Council has as yet taken no action upon the merits of the question of the advisability of legislation providing for the registering or licensing of practitioners of the professions named.

Report by Committee on Licensing Engineers

During the past fourteen months, this committee has had under consideration and study the subject of the licensing or registration of engineers. The fifteen members of the committee as appointed by Council, were selected from thirteen states, viz., Connecticut, New York, Pennsylvania, Ohio, Georgia, Louisiana, Illinois, Missouri, Iowa, Minnesota, Colorado, California and Washington, and therefore represent practically all sections of the United States, as well as, mechanical, electrical, mining, hydraulic, municipal, sanitary, railway and structural engineering, and also colleges of engineering.

The first work of the committee was to investigate the general subject and to collect, so far as possible, available material bearing upon the subject in hand, including opinions from many engineers as to the need or desirability of legislation, as well as copies of all state laws passed and proposed, having to do with licensing or registration of engineers, architects and surveyors.

This preliminary investigation disclosed that very pronounced views were held by engineers throughout the country, both for and against state licensing or registration. The general sentiment one year ago was more opposed to such measures than it is today. The older members of the profession did not as a rule favor licensing nor did they feel there was need for state regulation of engineering practise, while among the younger men there was a feeling that licensing or registration by the states would add prestige to professional engineers and in many ways benefit the profession, as well as individual engineers.

The advantages claimed for state licensing or registration are the same as those presumably gained by the laws regulating the professions of law and medicine, namely, that those who are incompetent and unqualified professionally to practise are unable to obtain certificates or licenses and hence both the public and the profession are protected. On the other hand, those engineers who have already attained to recognized professional standing feel they not only do not need the benefits claimed for such legislation, but they fear that state licenses or certificates of registration are apt to put the seal of state endorsement on men who do not deserve it and that the public would assume that a licensed or registered engineer was thereby certified by the state as fully qualified, regardless of what might or might not be the requirements demanded before a license or certificate was granted.

However, the question has gone beyond the stage of debate, for already ten states* have enacted laws licensing or registering engineers, and other states are certain to enact similar laws during the present or coming sessions of their legislatures. In addition to these ten laws governing engineering practise, there are at least six states that require the licensing or registration of

*Colorado, Florida, Idaho, Illinois, Iowa, Louisiana, Michigan Nevada, Oregon, Wyoming.

land surveyors and in at least eighteen states†, laws have been passed licensing or registering architects. Some of these ten laws are so drawn as to include both engineers and surveyors and some include engineers and architects and one or two include engineers, architects and surveyors. Moreover, these laws are not at all uniform and in several instances are likely to prove seriously embarrassing and annoying to engineers whose activities extend beyond the limits of a single state. Because of the nature of professional engineering work the practise of an engineer frequently extends over several states and therefore it is vitally important, if there are to be state regulations for engineering practise that these regulations be made uniform so far as possible and that the engineering profession unites in wisely directing such legislation.

As stated, laws have been passed in seventeen states for licensing or registering architects and the American Institute of Architects has endorsed and advocated such legislation, considering that both the architects and the general public are benefited thereby. Unfortunately some of the laws for licensing architects have been so drawn as seriously to interfere with legitimate engineering practise and the "model law" proposed and advocated by the American Institute of Architects contains definitions of "Architecture" and "building" which, should such laws be passed and enforced, would prevent anyone but a "registered architect" from planning or supervising the construction of any structure or any of the appurtenances thereto; consequently under this head would come a structure having simply foundations and girders, whether "with or without appurtenances." Under this model law proposed by the American Institute of Architects no one but a registered architect shall prepare plans for or supervise the construction of a building, and a "building" is thus defined in Section 19:

"A building is any structure consisting of foundations, floors, walls, columns, girders, and roof, *or a combination of any number of these parts*, with or without other parts or appurtenances."

Since none but a registered architect shall have the right to design or supervise the construction of any structure or any *appurtenance thereto* this matter becomes of vital importance to mechanical, electrical, sanitary and mining engineers, as well as to structural engineers.

In the State of Illinois a similar law for licensing architects was passed several years ago, the rigid enforcement of which made it necessary for engineers to unite in having a "structural engineers' license law" passed by the legislature, and now there are two laws in force in Illinois, one for architects, the other for structural engineers.

In some states the laws enacted and proposed are intended to regulate the practise of architecture, while in the other states laws have been enacted the purpose of which is simply to protect the term "architect," but not intended to regulate the practise of architecture. In Wisconsin and several other states no one may use the title "architect" without first obtaining from the state a certificate of registration as a "registered architect," but anyone not an architect may prepare plans and supervise construction provided he does not style himself an "architect."

Therefore this committee at its meeting of October 13, 1919, adopted unanimously the following resolution:

Motion: the following is the sense of this committee relative to the desirability of a law licensing or registering engineers:

Resolved: The enactment of legislation to provide for the registration of professional engineers is desirable and necessary. Ten states have already enacted such legislation. Laws licensing architects have been enacted in several states and similar laws endorsed by the American Institute of Architects, are pending in several other states, which, if enacted, would prohibit engineers from continuing their customary and recognized practise. . . . Carried unanimously.

†California, Colorado, Florida, Idaho, Illinois, Louisiana, Michigan, Montana, New Jersey, New York, North Carolina, North Dakota, Oregon, Pennsylvania, South Carolina, Utah, Washington, Wisconsin.

This committee has made a very careful study of definitions for "engineer," "engineering," "architect" and "architecture," but it was found that any definitions for engineering would be so general as to include too much, or too specific to be sufficiently general, or too voluminous to be suitable to incorporate in a law. Some have endeavored to include in a definition of "engineering practise" all sorts and kinds of construction work, but engineering includes investigations as well as plans and no catalogue can well be prepared sufficiently detailed to include all sorts of engineering activities. Several definitions are included in the appendix to this report, and it will be seen that both engineering and architecture are broad terms involving construction and necessarily there can be no sharply drawn distinction. Architects in the broadest sense are engineers even if usually architecture is associated with ideas of artistic or decorative features. Architects are eligible to membership in the American Society of Civil Engineers and several architects are members.

The only basis on which the practise of any profession may be subject legally to state regulation is "in order to safeguard life, health and property." The state may not dictate that no one without a particular kind of artistic talent nor without a tenor voice may practise engineering or architecture, but it may legally require that no one shall practise architecture or engineering that is ignorant of the effects of loads and applied forces or incapable of determining the stresses in structures due to loads and applied forces and unable properly to proportion materials in structures to safely sustain such loads and forces.

Land surveying does not involve matters that would ordinarily jeopardize life and health, but property rights are vitally affected by land surveying, and many states have deemed it essential to place restrictions and safeguards about the practise of land surveying. Land surveying is associated with both engineering and architectural practise.

This commitee has therefore deemed it advisable and to the best interests of all concerned to include in one law, provisions for the registration of engineers, architects and land surveyors. It has recognized that the practises of engineering and architecture overlap in many instances, especially in connection with the larger projects of modern structures, where many branches of the arts and sciences are combined, involving architecture, structural, mechanical, electrical, sanitary, and other lines of engineering. There are ample reasons why architects alone should judge as to the qualifications of those desiring to practise architecture and why engineers alone should pass upon the qualifications of those desiring to practise engineering. Hence a bill for legislation has been drafted by the committee along these lines and it is confidently hoped that the objections expressed by the American Institute of Architects against laws which might provide jointly for the registration of engineers and architects will be overcome by the terms of the bill herewith submitted.

In fixing the qualifications for registration in our proposed bill, these have been purposely made high, but they have not been made unnecessarily difficult for reasonably competent men to meet. It is not intended that candidates would ordinarily be subjected to written examinations, but rather that the board of registration would pass upon the sufficiency of the professional record of each candidate. Minimum qualifications have been clearly set forth which must be met. In order to enable the board to pass upon candidates fairly, certain qualifications are specified as "prima facie evidence of fitness" which (unless other facts derogatory to a candidate are also in evidence) will permit the board to pass the candidate. This so called "prima facie evidence" is not required, but if the candidate can present such evidence his application is the more readily passed upon. For instance, a candidate need not be a graduate of a college of engineering or architecture, but if he is, it is to his advantage. Likewise a candidate need not be a full member of one of the national technical societies or institutes, but if he has won such full membership it is greatly to his professional advantage.

In the preparation of this bill an experienced research engineer, Capt. Raymond J. Roark, was first employed to assist the chairman and a preliminary draft prepared, based upon a comprehensive study of all the data and existing and proposed legislation available. This draft was then discussed and revised by the three Chicago members of the committee, Messrs. Arnold, Alvord and Condron, and the Chicago member of Council, Mr. Loweth. It was then sent to each of the fifteen members of the committee for comments and amendments. After these communications had been received by the chairman and had all been collated a meeting of the entire committee was called and held in Chicago, attended by eight members, Messrs. Arnold, Dunlap, Condron, Shenehon, Slater, Snyder and Woermann, and Mr. Loweth, of Council.

Fourteen sessions were held in the five days, with a stenographic reporter present and all of the communications, as well as additional data gathered by the Chairman, were carefully studied and a complete revision of the original draft made, which draft met the unanimous approval of all the members in attendance. This later draft was carefully edited and sent to the entire committee for approval or amendment, subject to a final editing by the chairman and Mr. Shenehon.

The committee unanimously approved the bill as sent out with minor suggestions for guidance in the final editing. This editing is now completed and the bill is submitted to Council, with this report and with the recommendation that Council approve and endorse the same as a bill for an act of legislation in each and every state, for the regulation of the practise of engineering, architecture and land surveying.

Respectfully,
Committee on Licensing,
T. L. Condron,
Chairman.

Members who are interested can obtain copies of the proposed bill by addressing Secretary Alfred D. Flinn, Engineering Council, 33 West Thirty-ninth Street, New York.

CURRENT ENGINEERING TOPICS

ANNUAL APPROPRIATIONS FOR TOPOGRAPHIC MAPPING

As the time for consideration of Departmental estimates for next year's Sundry Civil Appropriation Bill approaches, the National Service Committee of Engineering Council in cooperation with all state-geologists is urging prominent engineers in every Congressional district to bring pressure to bear upon their Congressmen. This has been accomplished by selecting a prominent engineer,—members of the founder societies in each Congressional district, and directly appealing them to request their Senators and Representative to support a $600,000 appropriation for topographic mapping.

The state-geologists have cooperated by sending these engineers complete information of the local conditions, so that they may be thoroughly conversant with their "back-home" requirements, and thus be more forceful with their men in Congress. Further, most of the state-geologists are endeavoring to get increased state appropriations for this important work, which will have to be matched by an equal Federal appropriation in most cases before they become available for expenditures.

The estimates submitted by the Secretary of the Interior call for an increased mapping program to cost $600,000 annually, instead of $500,000 which was last year's estimate. It will be recalled that the last Sundry Civil Appropriation Bill provided $375,000 for topographic mapping, which was less by $50,000 than pre-war annual appropriations for this work. This year's estimate contemplates a program that will complete topographic mapping in twelve years instead of one hundred years which will be required if the old appropriation is not increased.

NEW CHIEF OF ENGINEERS CORPS, U. S. ARMY

Announcement has just been made that Colonel Lansing H. Beach was appointed by the Secretary of War as Chief of Engineers. While Colonel Beach is best known for the work he has done in connection with Mississippi River projects, he has had the varied service which comes to all Engineer Corps officers who have spent most of their lives in its service. He has done extensive engineering work on Great Lake projects and was in charge of the important improvements of the harbors of Baltimore and Jacksonville. More recently he has been stationed at Cincinnati in charge of the construction of the system of locks and movable dams being constructed in the Ohio River. Colonel Beach has been prominently identified with the development of inland waterways as a member of the Mississippi River Commission, as a member of the Board of Engineers for Rivers and Harbors, and as an advisor to the Waterways Division of Railroad Administration.

TECHNICAL WORK AT THE BUREAU OF STANDARDS

Bulletins dated January 9th on the progress of experimental work that has been started at the Bureau of Standards are as follows:—1. Accuracy of Electrical Measuring Instruments. 2. Electron Tubes in Radio Telephone Transmitting Sets. 3. Recent Radio Publications. 4. Industrial Safety Standards. 5. Measurement of Thermal Expansion of Various Materials. 6. Service Tests of Concrete Floor Treatments. 7. Consistency and Time of Set of Neat Cement Determined by New Method. 8. Slag as an Aggregate for Concrete. 9. Flat Slab Investigation. 10. Manufacture of Automobile Crankshaft. 11. Investigation of Electric Welding. 12. Investigation of Chilled Iron Car Wheels.

Because of the current nature of these investigations the results are not generally put in printed form but complete data on the results of the work to date are always available on application to the Bureau of Standards or the National Service Committee in the Washington office of Engineering Council.

NEW BOARD OF SURVEYS AND MAPS

An executive order signed by the President December 30th created a Board of Surveys and Maps to coordinate the map-making activities in all branches of the Executive Departments. The exact text of this order follows:—

> "In order to coordinate the activities of the various map-making agencies of the Executive Departments of the Government, to standardize results, and to avoid unnecessary duplication of work, I hereby constitute a Board of Surveys and Maps, to be composed of one representative of each of the following organizations:—
>
> 1. Corps of Engineers, U. S. Army
> 2. U. S. Coast & Geodetic Survey, Department of Commerce
> 3. U. S. Geological Survey, Department of Interior
> 4. General Land Office, Department of Interior
> 5. Topography Branch, Post Office Department
> 6. Bureau of Soils, Department of Agriculture
> 7. U. S. Reclamation Service, Department of Interior
> 8. Bureau of Public Roads, Department of Agriculture
> 9. Bureau of Indian Affairs, Department of Interior
> 10. Mississippi River Commission, War Department
> 11. U. S. Lake Survey, War Department
> 12. International (Canadian) Boundary Commission, Dept. of State
> 13. Forest Service, Department of Agriculture
> 14. U. S. Hydrographic Office, Navy Department.
>
> The individual members of this Board shall be appointed by the Chiefs of the various organizations named and shall

serve without additional compensation. The Board is directed to make recommendations to the several Departments or to the President for the purpose of coordinating all map-making and surveying activities of the Government and to settle all questions at issue between Executive Departments relating to Surveys and Maps in so far as their decisions do not conflict with existing laws.

This Board shall perfect a permanent organization and shall hold meetings at stated intervals, to which representatives of the map-using public shall be invited for the purpose of conference and advice.

This Board shall establish a central information office in the U. S. Geological Survey for the purpose of collecting, classifying and furnishing to the public information concerning all map and survey data available in the several Government Departments and from other sources.

All Government Departments will make full use of the above Board as an advisory body and will furnish all available information and data called for by the Board. So much of the Executive Order of August 10, 1906, as grants additional advisory powers to the United States Geographic Board is hereby rescinded and these additional powers are transferred to the Board of Surveys and Maps.

WOODROW WILSON.

The White House
30 December, 1919"

The provision that the Board was to set up a permanent organization was carried into effect on January 13th when representatives from each of the above Departments met and elected O. C. Merrill, Chairman,—Chief Engineer, Forest Service, Department of Agriculture; William Bowie, Vice Chairman —Chief, Division of Geodesy, Coast & Geodetic Survey, Department of Commerce,—and Colonel C. H. Birdseye, Secretary,—Chief Geographer, Geological Survey of the Department of Interior.

It is hoped that this concentration of mapping work will permit larger proportionate appropriations for the country's mapping program under the direction of the Geological Survey. In bringing this matter to the attention of the President, Engineering Council realized the great value of making reliable maps of the whole country available to every branch of the engineering profession in the simplest and most direct way. This will be accomplished through the central information office provided in the Geological Survey to receive and distribute Government and public map data. Thus, if proper appropriations can be obtained and put to work under the Geological Survey, the engineers of the country as well as the Government departments will be greatly benefited.

CHARLES WARREN HUNT

APPOINTED SECRETARY EMERITUS OF A. S. C. E.

At the meeting of the A. S. C. E. Board of Direction of January 21, Dr. Charles Warren Hunt, who had served as Secretary of the Society for 25 years, and who had asked to be relieved from further active duty, was appointed to the newly created office of Secretary Emeritus, the appointment to take effect upon the election of his successor.

Dr. Hunt was born in New York City in 1858 and graduated from the New University in 1876. For sixteen years he was engaged in the practise of Civil Engineering until 1892 when he became Assistant Secretary of the American Society of Civil Engineers. Three years later he was elected Secretary of the Society, which office he has held for the past 25 years. During his term as Secretary the membership has grown from 1800 to 9400.

NOTES FROM NATIONAL RESEARCH COUNCIL

The Carnegie Corporation of New York has announced its purpose to give $5,000,000 for the use of the National Academy of Sciences and the National Research Council. It is understood that a portion of the money will be used to erect in Washington a home of suitable architectural dignity for the two beneficiary organizations. The remainder will be placed in the hands of the Academy, which enjoys a federal charter, to be used as a permanent endowment for the National Research Council. This impressive gift is a fitting supplement to Mr. Carnegie's great contributions to science and industry.

The Council is a democratic organization based upon some forty of the great scientific and engineering societies of the country, which elect delegates to its constituent Divisions. It is not supported or controlled by the government, differing in this respect from other similar organizations established since the beginning of the war in England, Italy, Japan, Canada, and Australia. It intends, if possible to achieve in a democracy and by democratic methods the great scientific results which the Germans achieved by autocratic methods in an autocracy while avoiding the obnoxious features of the autocratic regime.

The Council was organized in 1916 as a measure of national preparedness and its efforts during the war were mostly confined to assisting the government in the solution of pressing war-time problems involving scientific investigation. Reorganized since the war on a peace-time footing, it is now attempting to stimulate and promote scientific research in agriculture, medicine, and industry, and in every field of pure science. The war afforded a convincing demonstration of the dependence of modern nations upon scientific achievement, and nothing is more certain than that the United States will ultimately fall behind in its competition with the other great peoples of the world unless there be persistent and energetic effort expended to foster scientific discovery.

NATIONAL PUBLIC WORKS DEPARTMENT ASSOCIATION

The convention of the National Public Works Department Association was held in Washington, D. C. January 13 and 14, 1920, at the Willard. There were 95 delegates present representing societies with a membership of 90,000. The convention was a very optimistic one, and the measure advocated has developed an unexpected strength.

Chairman M. O. Leighton opened the meeting with a brief address, during which he said:

Our Government has always been wasteful in the conduct of its business. This has not been the result of any wrongful intent. Throughout a long period of years it has been accepted by the majority and the occasions have been sporadic when much thought has been given to it. Wealth usually begets thoughtlessness as to small wastes. So long as our bank balance is large we are not likely to be vigilant as to the price we pay. A few cents more per pound, a few dollars more per yard are paid without thought or hardship. And this was particularly true with respect to Government expenditures when we lived under an indirect system of taxation. Waste of ten million dollars by the Government was hardly appreciable when spread over the price of 10 million pounds of sugar, 10 million pounds of wool and millions of pounds of everything else that we bought in the open market. But now our system of taxation is direct. Every individual of more than nominal earning capacity is presented by the Internal Revenue Office with a bill for his share. And when our annual peace-time budget runs up to $5,000,000,000, as presented by the Secretary of the Treasury a few days since, we begin to think about that leakage.

That five billion dollar estimate will be pruned—severely pruned. That means that we must go without some things that wise and prudent men think we need or that it would be to our advantage to have. Are we then so poor as all that?

No one believes that we are, and yet our bill is so large that it pinches us to pay. The answer is that we are paying too much for what we get. The appropriations committees in Congress will spend the greater part of their time for the next three or four months in pruning those estimates—a laudable and necessary thing to do under the circumstances. But those hard-working men are saving at the spigot and wasting at the bung-hole. We here assembled are asking them to do the obvious thing. Give the Government a business-like organization. Coordinate the functions so that the processes of Government business shall dove-tail. Cut out the wastes and the duplications. Abolish the rivalry between departments. We advocate a Department of Public Works not merely to secure technical symmetry in our Federal organization, desirable as that end may be. Our advocacy is in its essential features an attempt to stop some of these leaks.

When this organization was set up at Chicago I think that none of us—certainly not the speaker—had an adequate idea of the scope of the movement. We saw a loose and inefficient public works organization, divided and sub-divided into many different provinces. As technical men we knew how organically wrong that was. Of the wastes and inefficiencies we were well aware. With the necessity for a coordinated structure, by virtue of which the technical and semi-technical fields of the Government could be rendered efficient and business-like we were profoundly impressed. But that our effort, our idea, our legislative bill would become the cornerstone of a structure embodying efficiency in all Departments of Government we could hardly foresee. As an organization our effort is still focused on a Department of Public Works and that alone. But we realize that with that principle established—that example set—reform in other provinces of Government business activity will occur by the mere logic of events. We are pioneers.

This is the reason why our project for a Department of Public Works strikes straight home to the business man, the manufacturer, the contractor and the merchant, all of whom are represented here today. The technical men who met at Chicago last April to set up this organization built better than they knew. While the project retains all the virtues that appealed to us when it was launched—of technical excellence, of rational government organization, of economy and efficiency, we now see that it reaches to National and to business prosperity, to the fiscal welfare of the Nation, to the individual welfare of the productive business.

Roll call of states on the status of the campaign showed much effective work had been done. It became apparent that the less crowded states had done the most successful work. Two states reported that their entire Congressional representation were committed to this measure.

The Jones-Reavis Bill was discussed and several objections raised to it, especially to the provisions transferring the Bureau of Education to the Department of Labor. The Convention adopted the following resolution to define its position on this subject and on other controversial sections, such as that providing for the transfer of the Forest Service from the Department of Agriculture.

This resolution is as follows:

1. The National Public Works Department Assn. must, under its articles of organization, confine its efforts solely to the creation of a Department of Public Works.

2. Section 3 of H. R. 6649—S. 2232 (the Jones-Reavis Bill) has nothing to do with public works. The only reason for its presence in the bill is that some departmental disposition must be made of the non-engineering bureaus in the Interior Department.

3. It is manifest that the numerous organizations which became affiliated under the name of National Public Works Department Association for a common public works purpose do not, by so doing, commit themselves with respect to any other question, national or otherwise. Therefore each affiliated organization may have and is entitled to express its views as to said Section 3 of the bill without in any way qualifying its approval of the remainder of the bill.

4. The National Public Works Department Association, as such, is therefore unable either to approve or to disapprove the specific assignments of bureaus in the said Section 3, and in advocating the bill before committees of Congress the agents of this Association are to be instructed to present this fact in an unmistakable way.

5. The National Public Works Department Association suggests to all affiliated organizations that they present to Congress their own individual views with respect to said Section 3, either through the legislative agents of this Association or otherwise.

6. The officers and directors of this Association are instructed to have the foregoing statements printed in suitable form and circulated as one of the campaign documents issued in support of this movement.

An address from Governor Frank O. Lowden "On What a Department of Public Works has done for Illinois" was read by Mr. Isham Randolph of Chicago. The meeting then adjourned and the delegates were organized into state teams preparatory to going to Congress the next day to interview their Senators and Congressmen.

The evening session was devoted to speeches by Congressman C. Frank Reavis of Nebraska and by Brigadier General R. C. Marshall, Chief of the Construction Division of the Army.

The Wednesday morning session was devoted to visiting Congressmen and Senators at the Capitol.

At two o'clock the Convention reconvened and roll call by states was taken on the results of the delegates' visits to their Congressmen. It was at once evident that the delegates had met a very pleasant reception and had encountered a real interest in this measure. The most common objection to it was the difficulty of getting new legislation on the calendar during this already crowded session. The Chairman of the Convention pointed out, however, that the Congressional calendar was always crowded, but that time was always found for those measures which Congress believed were demanded by the people.

The uniformly favorable reports from the state committees made the Convention feel that real progress had been made and that the real obstacle in the way was the inertia of the men who should be actively supporting this measure.

The question of finances was then discussed at some length. It developed that the Societies have made very small contributions to the support of this Association and that it has been supported by the contributions of individuals. The Committee recommended that each participating society be asked to assess their members at least one dollar ($1) per man. The Finance Committee notified the Convention that the need of money was acute and must be promptly met.

ADDRESSES WANTED

A list of members whose mail has been returned by the postal authorities, is given below, together with the addresses as they now appear in the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

Robert A. Allen, 390-22nd St., Milwaukee, Wis.
Robert F. Arnott, Amer. District Steam Co., No. Tonawanda, N. Y.
P. K. Chan, Canton Christian College, Canton, Ohio.
C. R. Collins, 506 Hanna Ave., Aberdeen, Washington.
Albert S. Crockett, U. S. Submarine Base, New London, Conn.
Duncan C. Douglas, Public Service Electric Co., Camden, N. J.
Leonard W. Egan, Elec. Furnace Co., Alliance, Ohio.
John Mc F. Fisher, Arapoho, Oklahoma.
G. Foung, Wedgeway Bldg., Schenectady, N. Y.
Jason L. Frye, Camp Kearny, Cal.
J. P. Gailunas, 100½ Can Couvor Ave., Detroit, Mich.
Albert Kalin, City Light Dept., Seattle, Washington.
Lionel D. Leonard, 681 Fifth Ave., New York, N. Y.
Lincoln Nissley, 1213 Pioneer Bldg., St. Paul, Minn.
George L. Sewell, Porter Bros., Norfolk, Va.
Bertrand Smith, Kellogg Hotel, Kellogg, Idaho.
Wm. A. Street, Gatun, C. Z.
Lieut. W. J. Strieby, 34 Simpson Road, Ardmore, Pa.
Lieut. T. W. Swartz, 53D Infantry, Chattanooga, Tenn.
A. S. Touche, 72 W. Adams St., Chicago, Ill.
R. M. Umberger, 504 W. King St., Lancaster, Pa.
James A. Young, 2504 Milan St., New Orleans, La.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

SERVICES AVAILABLE

YOUNG MAN; age 25, associate member desires position as Sales Engineer with headquarters at Louisville, Ky. with reliable company handling electrical equipment; has had operative, installation and selling experience and is full of energy; present salary $200 per month. What offers to live wire, clean cut young man in this territory? E-2030.

MOTOR DRAFTSMAN AND DESIGNER; age 30; married; desires change; 12 years' experience on motors, generators and electrical appliances. Services available at once. E-2031.

TECHNICALLY TRAINED ENGINEER; with eight years' experience in construction department of electric public utility corporation, now having immediate supervision of its drafting and engineering office desires change. Age 37, married. E-2032.

MR. MANUFACTURER. How much is this man's service worth to you? Age 34, technical education, Alexander Hamilton Institute business course, Emerson efficiency and scientific management course, 15 years' practical experience as shop foreman, production manager, designer of electrical machinery and purchasing agent; some sales experience. Willing to invest some capital if necessary. E-2033.

ELECTRICAL ENGINEER; University graduate; age 30; married; Two years Westinghouse test and service work, three years engineering construction experienced in power application; installation and operation, electrical test and service; desires position as electrical engineer in electrical power company or in electrical railway service. Location—Middle West or vicinity of New York. Salary $3,000. E-2034.

ELECTRICAL ENGINEERING GRADUATE; Columbia 1910. Experience; 1 year, Test Department of electric lighting company; 7 years, laboratories for testing electrical household devices; 1½ years' practical engineering with large traction company. Desires position in or near New York as sales or industrial engineer with good opportunity for advancement. Salary $2500—$3000. E-2035.

EXPERIENCED TEACHER AND EXECUTIVE; now head of department of electrical and mechanical engineering in one of the larger western universities, is available for suitable opening. Location—immaterial, but position must offer opportunities for growth and service. Confidential correspondence invited from anyone interested. E-2036.

EXECUTIVE ENGINEER; over ten years' experience on construction, maintenance operation, sales, and management of hydro-electric concerns, covering generation, transmission, and distribution of voltages from 110 to 60,000. Location Chicago or Europe. E-2037.

ELECTRICAL ENGINEER; age 37, ex-Professor last two years in engineering department of manufacturing company; would like to correspond with or meet man who can effectually use man of my training and experience. Salary approximately $4000. Kind of work, of little importance so long as engineering training and experience can function. E-2038.

DEVELOPMENT ENGINEER; age 36; thoroughly grounded in shop practise and having ten years' experience in the design of acoustic apparatus. Can show exceptional record of inventive ability. Salary $5000. E-2039.

SUPERINTENDENT OF POWER; or Chief Electrician; age 33; 15 years' practical experience on high and low-tension apparatus, switching equipment and transformer stations. Last four years in charge of construction and maintenance, large industrial plant. Available on short notice. Minimum salary $2400. E-2040.

YOUNG MAN; age 29; married; thorough practical experience as electrical contractor and in handling men; technical training and years of mechanical experience, desires position as electrical superintendent or assistant with reliable firm or as estimator with chance for advancement. Available July. Location—New England States. Salary $2500.00. Address: P. O. Box 107, Erie, Pa. E-2041.

ELECTRICAL ENGINEER; University graduate, Lieutenant Signal Corps; thorough business training; experienced in installation of motors; lightning arresters; wireless apparatus and military telephone systems; two years with power company in operation and maintenance work; one year research on methods of testing desires position as engineer or executive with power company or manufacturer. E-2042.

AMERICAN, TECHNICAL GRADUATE; nine years General Electric Company shop and traveling engineering experience, electrical and steam turbines, desires foreign traveling position for consulting electrical engineers or electrical manufacturing corporations, British possessions preferred. Member, competent, age 32; single, considering change about June first. E-2043.

ELECTRICAL ENGINEERING GRADUATE; 1917 B. S. degree; age 26; married, two years' experience in outside plant engineering of Bell Telephone System, desires position with hydro-electric concern in the design of transmission lines and substations. West preferred. Available on 30 days' notice. Salary $2000. E-2044.

ELECTRO-MECHANICAL DEVELOPMENTAL ENGINEER; of nine years' experience with induction apparatus and ignition systems, desires a permanent connection. Member A. I. E. E. and Assoc-Member A. S. M. E. Salary about $5000. E-2045.

WORKS ELECTRICAL ENGINEER; 5 years' experience; G. E. test, Manufacturing, industrial engineering, power plant design and operation; technical graduate; age 30; married; desires position along consulting or industrial engineering lines. Salary $2500. E-2046.

EX-ARTILLERY MAJOR; 12 years' experience in construction operation and maintenance of large high voltage steam and hydro-electric systems, also experience in irrigation and making reports; university education; desires position in Latin America or India. Knowledge of language, conditions, and labor of both countries. Now receiving $4000. E-2047.

CAPABLE EXECUTIVE; management, production or industrial engineer. Graduate M. E. and business training. Age 32; Twelve years' experience includes; draftsman, Allis-Chalmers shop apprenticeship, factory inventory and appraisal, power plant tests, superintendent of construction, superintendent 600 miles of trolley and transmission lines, chief engineer large industrial corporation, and superintendent research division. Salary $4200. Available 30 days. E-2048.

RESPONSIBLE ENGINEER; Graduate C. E.; married; age 33. 12 years' experience; supervisory work with well-known organizations on broad range of large power station, hydraulic, industrial plant and building work, both from office and construction standpoints. Capable on investigations, reports, business and executive relations. Minimum salary $4200. E-2049.

SALES ENGINEER; technical graduate in electrical engineering; 4 years' experience with manufacturing company of which all but four months has been on sales work. Available on reasonable notice. E-2050.

ELECTRICAL ENGINEER; age 27, experienced in electric railway and industrial plant engineering and electrical installations aboard ships, desires position in either sales or engineering department of concern offering good chance for advancement. Now in charge of design work (electrical) for freighters and tankers. Available on short notice. Salary $3000. E-2051.

TECHNICAL GRADUATE; 2 years Westinghouse test, 2 years responsible construction work with large operating company, 2 years Superintendent of power company in city of 70,000, available on two months' notice as Manager of Power Sales or Assistant to General Manager of Power Company. Salary $3000. E-2052.

ELECTRICAL AND MECHANICAL ENGINEERING GRADUATE; twelve years' experience including Allis Chalmers and General Electric tests, central station engineering, and commercial work with General Electric Company; chief engineer large hydro steam transmission company; age 35; available immediately; E-2053.

MECHANICAL ENGINEER; graduate; age 27; single; 4 years engineering department, large eastern public utility on design, construction and estimating of electrical structures and equipment for generating and substations, desires position with manufacturing concern where more rapid advancement to greater responsibility exists; employed; ex-service man; available on two weeks notice. E-2054.

GRADUATE ELECTRICAL ENGINEER; married, age 37, desires change from present position. Prefers construction or operation in Far East if salary justifies; although willing to go anywhere. Has had factory experience, central station operation, construction and executive experience with Westinghouse. At present engaged in operation and construction heavy electric railway work. E-2055.

ENGINEERING GRADUATE; E. E. and A. M.; desires position with corporation that wishes to establish electric power plants or manufacturing companies in Turkey. Knows conditions in Near East. In addition to English knows French, Turkish and German. 3 years with large electric operating Company in New York City, 1 year teaching Electrical Engineering in large American University. Can start trip in one month. E-2056.

ELECTRICAL ENGINEER; desires position with manufacturer of fractional horse power motors. Seven years' experience in design and manufacture; three years' in charge of production and design. Salary $4000. per annum. E-2057.

PRACTICAL ELECTRICAL MAN; Associate, with some technical training; capable of holding position as division superintendent for central station company or as supervisor of electrical construction; can estimate, layout or supervize installations of power plants or complete factory equipment of any size. Location preferred vicinity Pittsburgh or Baltimore. Present salary $3800. E-2058.

ENGINEER; experienced electrical design, construction and operation power plants and electrical equipment—inside and outside work; overhead and underground, private and public utility plant. Technical graduate, age 35, available March 1st; Salary $300 per month. E-2059.

SUPERINTENDENT OF POWER; with 18 years' experience in construction, operation and maintenance of steam and hydro-electric plants, high tension transmission systems, and distributions; desires position with either a construction company or an operating company. Also familiar with the commercial end of the work. E-2060.

YOUNG MAN, 23, energetic and ambitious, electrical engineering graduate 1919 with B.S. degree, desires position in engineering department of firm where he is given an opportunity to advance according to ability shown. Have had 2½ years' experience as draftsman. E-2061.

ELECTRICAL AND MECHANICAL ENGINEERING GRADUATE; age 26, associate; two years' experience testing and inspecting electrical devices; one year on experimental development work; desires permanent position with opportunity for advancement. References regarding ability available. New York or vicinity preferred. Available immediately. Salary expected $1900. E-2062.

ELECTRIICAL ENGINEER; M. I. T. 1909, age 34, married, open for engagement as sales, consulting or developing engineer, ten years of exceptional broad experience in design, construction, operation, maintenance, testing and machine and process development engineering. Salary $4,000 to $5,000. Available on short notice. E-2063.

EXECUTIVE; with broad engineering training; construction and operating experience; 15 years in hydro-electric and kindred industries. War work:—designed, built and successfully operated large American and British munition plants. Good organizer and handler of men; familiar with modern manufacturing practise. Age 38; American. E-2064.

GRADUATE ELECTRICAL ENGINEER; (1914) desires position in engineering department of growing industrial concern or consulting engineering firm. 3½ years' experience with large public utility in design and layout of outside plant; 2 years with consulting engineers, handling public utility problems. Age 28, single. Available on short notice. E-2065.

ELECTRICAL ENGINEER; Nineteen-sixteen Mass. Inst. of Tech. graduate; recently discharged officer, Engineer Corps; eighteen months experience in rate research, valuation and cost engineering; desires position with firm of consulting engineers making financial and engineering investigations or with institution which finances public utility developments. Minimum salary $2400. E-2066.

TECHNICAL GRADUATE; with 2½ years broad practical experience in power installations for industrial plants. Complete experience from boiler room to engine room, high and low tension distribution, lighting, motors and their equipment. Above experience obtained as mechanic in construction and maintenance and as operator. References furnished. E-2067.

EXECUTIVE ENGINEER with rich mechanical and electrical experience in design and construction of special machinery, also quantity production electrical machinery; desires position as General Manager of manufacturing concern. Has done considerable organizing, systematizing and development work. Graduate in Electrical Engineering. Age 33. Available soon. E-2068.

ENGINEERING GRADUATE, GE testman, experienced in hydro and steam generation, oil and coal fuels. Twelve years experience, master mechanic and chief electrician, gold, silver, quicksilver and coal mining and mill treatment. Desires charge, mechanical and electrical equipment of mining company in western states. Salary $250. E-2068.

OPPORTUNITIES

ELECTRICAL ENGINEER with first class experience in both large and small transformer engineering. Would go into transformer engineering department of large manufacturing company as assistant engineer. Duties will include much special development work. Location Indiana. R-2447.

GENERAL MANAGER for company manufacturing complete line rubber covered wire ranging in size from lamp cord to mining machinery cable. Applicant must thoroughly understand business. Company's financial position and standing in the trade are good. Will sell stock on favorable terms, to experienced and qualified man. R-2453.

ELECTRICAL ENGINEER capable of designing and developing street and commercial lighting fixtures and appliances. Should be able to do drafting as well as designing and should be conversant with construction and line material as well as fixtures. Man with some central station experience preferred. Location Philadelphia, Pa. R-2458.

SALES ENGINEER to open up outside territory for the sale of automobile tires after two or three months training in vicinity of New York City. Some selling experience essential. Man between 30 and 40 years of age desired. R-2459.

ENGINEER; expert in the manufacture of toy transformers. Only man with thorough knowledge of manufacture of large quantities of toy transformers can qualify. Location—New Jersey. R-2461.

EXECUTIVE with accounting experience for work with company manufacturing small machinery parts. Location New York City. R-2462A.

SALES ENGINEERS for commercial application of the product of large manufacturer of electrical equipment. Location Pennsylvania. R-2463.

RESEARCH FELLOWSHIP in acoustics has been established for the encouragement of investigation in this science; at middle western technical institution. Candidates must be college graduates and have at least one year of advanced study in physics. Stipend is $1000 per year. Location Ohio. R-2465.

OPERATING ENGINEER; must be technical graduate with considerable experience in construction, operation and maintenance of hydraulic and steam generating plants and overhead and underground transmission and distribution systems. The present system includes a 20,000 K. W. hydro-electric plant and two auxiliary steam plants, 44,000 volts and 12,000 volt transmission system and 2300/4000 volt distribution system with ten substations. Will have direct charge of operation and maintenance of entire system. Applicant must have had similar work and responsibilities with central station Company. Location Chicago, Ill. R-2493.

ENGINEER OF PLANS AND RECORDS; to take charge of division, the work of which consists of the preparation of plans, specifications and estimates of all additions to or changes in the present generating, transmission and distribution systems, inspection of all work and keeping of records of operation, construction and maintenance. Also necessary that the men be qualified to take charge of operation of system during absence of Operating Engineer. The man for this position must be technical graduate with experience in the design, operation and maintenance of central station systems with some experience in general office methods and systems of records. Must also have experience in the preparation of plans specifications and estimates for work in connection with central station properties. R-2494.

DRAFTSMEN for design of radio apparatus. Position at Radio Laboratories, Camp Alfred Vail, (Little Silver), New Jersey. Pay $2100 to $2500 per annum. Give details as to age, experience and references. R-2505.

MECHANICAL OR ELECTRICAL ENGINEER with experience in the design of radio apparatus to take charge of drafting room. Position at Radio Laboratories, Camp Alfred Vail, (Little Silver), New Jersey. Pay about $3000 per annum. Give details as to age, experience and references. R-2506.

ASSISTANT EDITOR; for *The Electric Journal*, 1204 Keenan Building, Pittsburgh, Pa. Must be a technical graduate, have a pleasant personality, originality and imagination. Young man preferred. Salary dependent upon qualifications. R-2508.

MAINTENANCE ENGINEER to take charge of electrical power plants and steam turbines on phosphate rock producing property. Westinghouse turbines installed. Liberal salary. Location Nichols, Florida. Living conditions reasonably desirable. R-2511.

WELL ESTABLISHED COMPANY in the middle west manufacturing electrical devices, wiring material, outlet and switch boxes, fittings for conduit and armored cable, and the like, wishes to employ competent engineer, with experience in designing such material, to develop additional lines for it to manufacture and to improve its present product. Location Pennsylvania. R-2513.

MACHINE-SHOP DISPATCHER with thorough knowledge of automotive industry pertaining to production work; must be able to assign different jobs and operations to workmen and keep them supplied with necessary material. Excellent opportunity. Location Michigan. R-2524.

RECENT GRADUATES to qualify as chemical engineers, gas operators, electricians, etc. in plant of large manufacturing company. Location Tenn. R-2527.

RESEARCH ENGINEER. Excellent opportunity for right man, with one of the largest concerns of its kind in the United States. Location Chicago. Must be technical graduate with 8 or 10 years of general engineering experience, including designing, experimental engineering, compilation of data, planning and working out of an assigned subject. Must have initiative and tact. Write, giving references, age, experience and salary. R-2529.

YOUNG ENGINEER, technical graduate, to assist in testing and research department. Knowledge of combustion and boiler tests is requisite. In writing give references, experience and age. Location Detroit. Z-21.

INDUSTRIAL RELATIONS DIRECTOR age 30 to 40 years, with about 10 years experience in manufacturing industry, preferably in production work, and about 2 years in employment work; broad guage and high class man wanted. Salary $4000-5000. Location Rochester, New York. Z-22.

SALES ENGINEER for New York City and vicinity. A young engineer, graduate preferred, but essentially a salesman, experienced in selling pumping machinery, steam engines, boilers and general power plant accessories. Good opportunity with progressive organization. Z-53.

DRAFTSMEN WITH EXPERIENCE IN MECHANICAL AND ELECTRICAL LINES, for position with company manufacturing radio and electrical equipment. Salary $35 per week. Location New York State. Z-57.

PATENT ENGINEER; must be a technical graduate and be able to prepare new engineering developments for patent protection. Qualifications: Inventive ability, excellent general theoretical knowledge in chemistry, physics and engineering, as much knowledge as possible of manufacturing and knowledge of patents. Must have ability to take engineer's ideas and expand them into broad patent claims. Excellent opportunity for man of theoretical and scholastic taste. Location Connecticut. Z-60.

ELECTRICAL ENGINEER with technical training to install and supervise operation of A-C. Motors, Steam turbo generator, etc. Salary $275 per month. Location Illinois. Z-66.

ASSISTANT ENGINEER with experience in transmission and differential work for position with company manufacturing automobile gears. Must be thoroughly familiar both with production, manufacture, and operation. Salary $250-300 per month. Location, Ontario. ½ hour from Buffalo. Z-77.

TECHNICALLY TRAINED, EXPERIENCED EXECUTIVE to take charge of a plant manufacturing a line of electrical machinery, both A-C. and D-C. Must be thoroughly experienced along electrical manufacturing lines and be able to guide design as well. Location Chicago, Ill. Z-86.

MAINTENANCE ENGINEER; with about 5 years' drafting experience; will be required to do some drafting as well as set up machines. Mature man desired. Salary $175-$200 per month. Location—New Jersey. Z-95.

ELECTRICAL DRAFTSMAN familiar with layouts, wiring diagrams, etc. for mill and power house work. Work consists of layout for steam and hydro-electric power plants, transmission line work, switchboard layouts, and distribution in mills. Capacity of work runs into thousands of kilowatts in some installations. Man who can make accurate calculations on electrical requirements, work up drawings, and trace them needed. Location New York City. Z-100.

INSTRUCTOR for a 60 hour course on non-textiles to be given in a training school for teachers of retail selling. Course must be non-technical in the sense that it is not meant for workers in any of these lines but for teachers of salespeople who must know their goods from the sales point of view. Location New York City. Z-101.

YOUNG ENGINEER for rating and underwriting of automobile insurance risks for the United States. Must be willing worker, good at mathematics, agreeable and ambitious. Preferable that applicant know something about the various makes of automobiles. Location New York City. Z-108.

SMALL D-C. GENERATOR DESIGNER, with knowledge of costs, sources of supply, manufacturing methods, and ability to compute electrical data, for full or part time work. Must have practical experience. Man acquainted with brush arc type machine preferred. Liberal pay for real expert. Location New York City. Z-110.

INDUSTRIAL ENGINEER; large firm of industrial engineers is constantly on lookout for qualified high grade men. They need not be technical graduates but it would be advantageous. Must have successful executive manufacturing record and be experienced in organization, management, production control, incentives, manufacturing methods and processes, stores control, employment and personnel work and have some knowledge of cost accounting. Should have practical knowledge of operation of machine tools, metal or woodworking or both. Men who have had experience as general managers, works managers, factory managers, superintendents, production managers, etc., are type desired. Applicant would be located in different localities for average of six months at a time. Salary commensurate with ability. Z-111.

FIRST CLASS ELECTRICAL DESIGNING DRAFTSMAN; Salary $250 per month. Location Connecticut. Z-119.

FIRST CLASS GENERAL MECHANICAL DESIGNING DRAFTSMEN for power house and Industrial Plant work. Salary $250 to $275 according to ability. Location Connecticut. Z-120.

CHASSIS TESTER AND INSPECTOR for electric vehicles. Duties to be read testing, mechanical inspection and running in of electric vehicle chasses, as well as inspection of workmanship on chasses and bodies. Location Mt. Vernon, New York. Z-121.

RESEARCH GRADUATE ASSISTANTSHIPS in Engineering Experiment Station of the University of Illinois are open to graduates of approved American and foreign universities and technical schools prepared to undertake graduate study in engineering, physics or applied chemistry. Appointment must be accepted for two consecutive collegiate years, at the expiration of which period if all requirements have been met, the degree of Master of Science will be conferred. Annual stipend $500. For additional information address; The Director, Engineering Experiment Station. University of Illinois, Urbana, Ill. Z-123.

GRADUATE ELECTRICAL ENGINEER for position with company manufacturing cables. Location vicinity of New York City. Z-152.

TECHNICAL ENGINEER with at least two years experience in operation of steam power plants, duties would include estimates, reports and general work of an engineering nature required by large central station and isolated heating plants. Position is in the Steam Engineering Department of a public utility. Location St. Louis, Mo. Z-161.

RECENT GRADUATES of Mechanical or Electrical Engineering courses for engineering work connected with production of electrical and mechanical devices. Send application to Mr. J. C. Wilson, the Cutler-Hammer Mfg. Co. Milwaukee. State training, experience in industrial plants, if any, references and other information concerning yourself. Z-164.

ELECTRICAL ENGINEER experienced in transmission line, substation and distributing construction; preferably one with some power plant construction or operating experience. Man would be Assistant to Engineer in charge of construction work for electric properties which are undergoing rapid expansion. Duties would consist of both office and field work, and cover both design and construction of extensions of the above character. Location Texas. Z-165.

DISTRIBUTION ENGINEER ASSISTANT for underground and substation design. Must be graduate Electrical Engineer. State age, education, experience etc. Location, Middle West. Z-166.

ELECTRICAL ENGINEER GRADUATE with one or two years experience in small motor construction is offered unusual opportunity to qualify for sales force of large motor manufacturing concern. Immediate duties would be to take care of office and of sales in Chicago office and to handle correspondence incident thereto. Resulting familiarity with trade would lead to attractive future. Young unmarried man preferred. Z-167.

ENGINEER for supervising the construction of Hydro Electric Power Plant. Vacancy will call for Resident Civil Engineer to supervise construction, including dam, power station and transmission line. Previous experience on similar work essential. Location Northern Ontario, Canada. Z-186.

SALES ENGINEERS; young men, preferably with mechanical or electrical education and training, although any technical graduate would be considered. Not much sales experience necessary, but men must possess sales potentiality. Salary $150 up depending upon qualifications. Location New York City. Application by letter with which should be enclosed recent snapshot. Z-193.

SALES ENGINEERS; college graduates; some steam engineering experience desirable; must have good personality. Location New York City. Z-198.

RECENT TECHNICAL GRADUATE, with some executive ability, who wishes to take up work in the Engineering Department of a public utility in the Middle West. Salary to start $100, with an excellent opportunity for advancement. Applicant need not have any particular experience, providing he has the capacity for learning. Z-203.

FOREMAN AND ELECTRICAL DEPARTMENT; old established concern, located about 200 miles west of New York City, manufacturing high grade, electro-mechanical devices for low tension service has vacancy for thoroughly experienced Foreman. Must essentially be first-class mechanic, to work accurately to drawings, and specifications; well trained to progressive assembly and first-class workmanship in every detail; good leader of men with qualifications to expand with increasing responsibilities. Position offers exceptional opportunity for advancement. Reply in own handwriting, giving full particulars of experience; references; age; nationality. Replies treated as strictly confidential. Z-210.

POWER-SALESMAN; graduate electrical engineer; familiar with electrical machinery and capable of studying and developing applications for the use of electricity. This is very good opportunity for capable and energetic young man; Location Minnesota. Initial salary $150. Z-214.

JUNIOR ELECTRICAL ENGINEERS: recent graduates, for work with large industrial corporation. Location Massachusetts. R-2328.

TECHNICAL GRADUATES wanted for engineering calculations, drafting and research work in connection with steam turbine design. Leading to engineering positions. Z-229.

FIRST CLASS ENGINEERS AND DRAFTSMEN experienced in design of heating and ventilating systems, power plants, electric wiring layouts, sprinkler systems and plumbing. Salaries range from $200 to $300 per month. In reply state education, experience in detail, salary expected and earliest date you could report for work. Address Smith, Hinchman & Grylls, Architects and Engineers, 710 Washington Arcade, Detroit, Michigan. Z-230.

PERSONAL

DAVID S. WEGG, JR., formerly Inspector of Ordnance, Standard Car Co., Hammond, Ind., has become affiliated with the Chicago office of the Allis-Chalmers Mfg. Co. as sales engineer.

GEORGE E. ARMSTRONG, formerly Protection Engineer with the Southern California Edison Company, is now Associate Editor of the *Journal of Electricity*. His address is 531 Rialto Building, San Francisco.

J. B. HARRIS, JR., has resigned his position as Pittsburgh manager for the Pittsburgh Transformer Company, Pittsburgh, Pa., to become associated with Harris and Evans, District Managers, 902 Real Estate Trust Building, Philadelphia, Pa.

J. R. TEMPLIN, Consulting Engineer of Christchurch, New Zealand, was a visitor at Institute headquarters January 14. He is visiting the United States to obtain information regarding the latest developments in the electrical industry.

CLARENCE GOLDSMITH, who has been engineer for the National Board of Fire Underwriters for the past twelve years and late Major in the Construction Division of the Army, has been placed in charge of the branch engineering office recently established by the National Board at 234 South La Salle Street, Chicago, Ill.

CARL A. BAER, formerly Captain Baer, 56th Engineers, U. S. Army, announces that he has formed a partnership with MERRITT T. COOKE, JR., formerly of the Engineer Corps, U. S. Army, and that the business will be conducted under the firm name of Carl A. Baer & Company, Engineers, with offices in the Land Title Building, Philadelphia.

H. A. P. LANGSTAFF, who has been with the J. G. White Engineering Corporation as Field Electrical Engineer on the construction of the power house involving installation and test of one 60,000-kw. steam turbine for the U. S. Nitrate Plant No. 2 at Mussel Shoals, Alabama, has recently become connected with the West Penn. Power Company of Pittsburgh.

N. G. LINDSTROM, formerly with the S. K. F. Ball Bearing Company, Hartford, Conn., has been appointed by the Roller-Smith Company, New York City, as Works Manager of its plant at Bethlehem, Pa. He is a graduate of the Royal Institute of Technology at Stockholm, Sweden, and since his graduation has had wide experience with electrical and engineering concerns which makes him particularly well fitted to assume his new duties.

WALTER W. GASKILL has been appointed to represent the Roller-Smith Company, New York City, in New England territory. He will handle also products of the Ward-Leonard Electric Company, Mt. Vernon, N. Y., and the Brown Instrument Company, Philadelphia, Pa. From June 1918 until April 1919 Mr. Gaskill was located in Washington with the Bureau of Aircraft Production, his particular work being in connection with the development and production of mobile lighting outfits for the illumination of aviation fields for night flying.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

BOOK NOTICES (DEC. 1st–31st, 1919)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

L'ALUMINIUM DANS L'INDUSTRIE. Métal pur Alliages D'Aluminium.

By Jean Escard. Paris, H. Dunod et E. Pinat, 1918. 272 pp., illus., 10 x 6 in., 18 francs. (Purchase.)

The subjects discussed include the manufacture of aluminum, its physical and chemical properties, soldering, the influence of mechanical treatment on its properties, and its applications in metallurgy, electrical and mechanical industries, etc. The constitution, properties and uses of the various aluminum bronzes and alloys of aluminum with various metals, both common and rare, are described, and a final chapter treats of alloys with silicon, aluminum carbides and nitrides, and several alloys for special purposes. The volume gives a concise survey of present knowledge of aluminum.

APPLIED SCIENCE FOR METAL WORKERS.

APPLIED SCIENCE FOR WOOD-WORKERS.

By William H. Dooley. N. Y., The Ronald Press Co., 1919. $2 each.

These volumes present a course in the general principles of science, which gives particular attention to their applications in industry and is intended for use in vocational high schools, industrial schools, apprentice classes, etc.

The general scientific matter in the two books is identical. Additional material relating specifically to the woodworking trades appears in one, while the other treats of metal-working in similar fashion.

BUILDING OF THE PACIFIC RAILWAY.

The Construction-Story of America's First Iron Thoroughfare between the Missouri River and California, from the Inception of the Great Idea to the Day, May 10, 1869, when the Union Pacific and the Central Pacific joined tracks at Promontory Point, Utah, to form the Nation's Transcontinental. By Edwin L. Sabin. Philadelphia & London, J. B. Lippincott Co., 1919. 317 pp., 10 pl., 4 por., 1 map, 8 x 5 in., cloth, $2.

Mr. Sabin's object has been to tell how the Pacific railway came into being; to describe the actual building operations by which the Union Pacific Railroad, from the Missouri River, and the Central Pacific Railroad, from the Sacramento River, were constructed in six years instead of the allotted fourteen. The book is a popular, readable account of the men who built the roads and of the methods used.

CLAY PLANT CONSTRUCTION AND OPERATION.

By A. F. Greaves-Walker. Chicago, Brick and Clay Record, 1919. 212 pp., 79 illus., 9 x 6 in., cloth, $4.

In writing this work the author has attempted to explain in understandable English some of the problems of the manufacturer of structural clay products. Technical terms, formulas, and theories have been avoided, and practical facts alone presented.

ELECTRICAL ENGINEERING PAPERS.

By Benjamin G. Lamme. This volume contains a collection of the author's most important engineering papers presented before various technical societies and published in engineering journals and elsewhere from time to time. 1919. Published by Westinghouse Electric & Mfg. Co. 773 pp., illus., 9 x 6 in., cloth, $2.50. (Gift of author.)

A collection of thirty-one papers and addresses which have appeared in various periodicals during the period from 1897 to 1918. These papers deal with problems of generator and motor design, the history of direct-current generators and of street railway motors, and with technical training. The volume is published by the Westinghouse Electric and Manufacturing Company to commemorate Mr. Lamme's connection with it for thirty years.

ELEMENTARY PRINCIPLES OF AEROPLANE DESIGN AND CONSTRUCTION.

A textbook for Students, Draughtsmen, and Engineers. By Arthur W. Judge. Lond. and N. Y., James Selwyn and Co., Ltd., 1919. 116 pp., 56 illus., 13 tables, 9 x 6 in., cloth, $3. (Gift of Isaac Pitman & Sons.)

Written to provide an inexpensive book, of an elementary nature, dealing with the fundamental principles of the design and, to a certain extent, the construction of airplanes. Follows the plan of the author's larger work, to which it may serve as an introduction.

GUIDE TO THE STUDY OF THE IONIC VALVE.

Showing its Development and Application to Wireless Telegraphy and Telephony. By William D. Owen. Lond., Sir Isaac Pitman and Sons. 59 pp., 12 illus., 6 x 4 in., cloth, $1.

This little volume is intended to provide, for students of radio-telegraphy, an impartial, coherent record of the development of the ionic valve. References to the original sources of the information enable the reader to pursue his study of the subject.

INDUSTRIAL RECONSTRUCTION PROBLEMS.

Complete Report of the Proceedings of the National Engineers. New York City, March 18-21, 1919. 197 pp., 9 x 6 in., paper.

The papers presented at the conference dealt with a wide variety of problems connected with the reorganization of our industries on a peace basis. Consideration is given to questions of finance, commerce, production, labor, education, management, etc.

MACHINE TOOL OPERATION.

Part I. The Lathe Bench Work and Work at the Forge. By Henry D. Burghardt. 1st edition. N. Y., McGraw-Hill Book Co., Inc., Lond., Hill Publishing Co., Ltd., 1919. 326 pp., illus., tables, 8 x 5 in., cloth, $2.

The author of this work has used his experience as a teacher of machine work in a technical high school to prepare a textbook for those who desire a knowledge of the principles and elementary operations of machine shop work, suitable for use in technical and trade schools and in apprenticeship courses. While designed primarily for use in connection with lectures by an instructor, it is also useful for self instruction.

THE MANUFACTURE AND TESTING OF MILITARY EXPLOSIVES.

By John Albert Marshall. 1st edition. N. Y., McGraw-Hill Book Co., Inc., Lond., Hill Publishing Co., Ltd., 1919. 261 pp., 8 x 6 in., cloth, $3.

This volume contains a concise account of the explosives used for military purposes, in which attention is directed to those points which have a direct bearing on the manufacture, testing and storage of these substances. An extensive bibliography is included.

METAL WORKER'S HANDY-BOOK OF RECEIPTS AND PROCESSES.

Being a collection of chemical formulas and practical manipulations for the working of all the metals and alloys; including the decoration and beautifying of articles manufactured therefrom, as well as their preservation. Edited by William T. Brannt. New enlarged edition. N. Y., Henry Carey Baird and Co., Inc., 1919. 582 pp., illus., tables, 8 x 5 in., cloth, $3.

Five new chapters have been added to the present edition of this work, describing methods for welding with the oxy-acetylene flame, thermit and electricity, for galvanizing and for die casting.

MILLIONS FROM WASTE.

By Frederick A. Talbot. Phila., J. B. Lippincott Co.; Lond., T. Fisher Unwin Ltd., 1920. 308 pp., 9 x 6 in., cloth, $5.

This work is written to indicate certain of the most obvious channels through which wealth incalculable is being permitted to escape, as well to describe some of the highly ingenious efforts which are being made to prevent this wastage. While written essentially for the uninitiated, it will, the author hopes, prove of aid to those who are fully alive to the potential values of refuse. The volume is confined to those phases of the subject which are familiar to the average person.

OIL ENGINES. DETAILS AND OPERATION.

By Lacey H. Morrison. 1st Edition. N. Y., McGraw-Hill Book Co., Inc.; Lond., Hill Publishing Co., Ltd., 1919. 472 pp., illus., tables, diagrams, 9 x 6 in., cloth, $5.

This volume is intended for operators of oil engines. The details of construction of the more important oil engines manufactured in the United States are described and the proper methods of adjustment are explained at length.

THE PETROLEUM HANDBOOK.

By Stephen O. Andros. Chic., The Shaw Publishing Co., 1919. 206 pp., illus., tables, 7 x 4 in., flexible cloth, $2.

In a book of pocket size, the author gives the fundamentals of each phase of the oil industry necessary to a clear understanding of the various operations entailed between the location of an oil well and the distribution of the refined products. The work is chiefly a compilation from the standard authorities, arranged for those who wish a brief, accurate account of the industry, devoid of unnecessary detail.

PRINCIPLES OF INDUSTRIAL ORGANIZATION.

By Dexter S. Kimball. 2nd edition, rev. and enlarged. N. Y., McGraw-Hill Book Co., Inc.; Lond., Hill Publishing Co., Ltd., 1919. 325 pp., 21 illus., 1 pl., 12 tables, 9 x 6 in., cloth, $3.

This work, the first edition of which appeared in 1913, has been written to give young engineers a concise account of the salient facts regarding the most important economic and sociological problems with which they will be brought in contact, and to explain the origin and growth of the important features of industrial organization. The present edition has been revised, rearranged and enlarged.

SELENIUM CELLS.

The Construction, Care and Use of Selenium Cells with special reference to the Fritts Cell. By Thomas W. Benson. N. Y., Spon and Chamberlain; Lond., E. & F. N. Spon, Ltd. 1919. 63 pp., 18 illus., 8 x 5 in., cloth, $1.50.

The lack of definite information on the construction of selenium cells has led the author to publish the results of some of his experiments.

After a brief review of various types of cells, the book describes in detail the manufacture, maturing and testing of the Fritts cell, and concludes with an account of some applications and suggestions on the care of cells.

STRENGTH OF MATERIALS.

A Textbook for Technical and Industrial Schools. By John Paul Kottcamp. 1st edition. N. Y., John Wiley and Sons, Inc.; Lond., Chapman and Hall, Ltd., 1919. 193 pp., 103 illus., 19 tables, 8 x 5 in., cloth, $1.50.

The course of instruction presented in this textbook sets forth the fundamental principles with a minimum of mathematics, and shows the application of these principles by a large number of examples which are worked out in detail. The book is based on the author's course in the subject at Pratt Institute.

TECHNISCHER LITERATURKALENDER. 1918.

München-Berlin. R. Oldenbourg, n. d. 640 columns, 1 por., 8 x 6 in., cloth, 12 marks plus 20% increase.

This volume is a concise biographical dictionary of living German authors of technical and scientific books, compiled by the Librarian of the German Patent Office. Over five thousand writers are included. The information given includes their addresses, education, age, occupations, technical specialties, publications, etc.

TECHNO-CHEMICAL RECEIPT BOOK.

Containing Several Thousand Receipts and Processes, Covering the Latest, Most Important and Most Useful Discoveries in Chemical Technology and Their Practical Application in the Arts and the Industries. Compiled and edited by William T. Brannt and William H. Wahl. New enlarged edition. N. Y., Henry Carey Baird and Co., Inc., 1919. 516 pp., illus., tables, 8 x 5 in., $2.50.

The principal aim in preparing this work has been to give a compendious collection of approved receipts and processes of practical applications in the industries. The receipts have been principally derived from German sources and most of them have been tested practically. The present edition has been revised and various receipts added.

WHEN THE WORKMEN HELP YOU MANAGE.

By William R. Basset. N. Y., The Century Co., 1919. 266 pp., 7 x 5 in., cloth, $2.

The author states that, as a result of large practical experience, he has come to the conclusion that right relations between employers and employees depend upon the establishment of arrangements by which both parties may express themselves in their work, without the intervention of outside agencies. In this book he develops certain principles underlying satisfactory relations and gives examples of their successful application by various industrial concerns.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Baltimore.—December 12, 1919, Johns Hopkins University. Paper: "Power for Electro-Mechanical Industries" presented by Professor Richards. The paper was illustrated with lantern slides, and Professor Richards gave a most lucid outline of the methods used by the electro-mechanical industries and of their power requirements. Attendance 86.

Boston.—December 9, 1919, Engineers Club. Paper: "Electric Power Transmission Cables." Speaker: Mr. W. H. Cole. The paper was illustrated by lantern slides. Attendance 125.

December 16, 1919, Cambridge. The Section was invited to participate in a trip and meeting with the A. S. M. E. The party met at the gate of the Watertown Arsenal, Watertown, Mass., and made an extensive tour of the Arsenal under the guidance of the superintendent. On the completion of the trip the party assembled at The Harvard Union, Harvard College, and a part of them made an inspection tour of the Laboratory of the new Harvard Engineering School. At 6:15 dinner was served at Harvard Union. During the dinner short addresses were made by Professors Hughes and Webster. At 8:00 p. m. the party assembled in Emerson Hall, Harvard University, and listened to a talk by Professor Albert Sauveur on "Metallography and Heat Treatment of Metals." Dr. Langenberg also addressed the meeting. Attendance 150.

January 6, 1920, Chipman Hall, Tremont Temple. Subject: "Electric Welding." Speaker: Professor C. A. Adams. Professor Adams' talk was illustrated with lantern slides, and he gave a history of welding and the welding organization. The discussion was participated in by Professor Elihu Thomson, F. L. Fairbanks and others. Attendance 175.

Cleveland.—December 16, 1919, Cleveland Engineering Society. Paper: "The Manufacture and Magnetic Testing of Electric Sheet." Speaker: Mr. W. J. Beck, Research Director, American Rolling Mills Co., Middletown, Ohio. Attendance 95.

Detroit-Ann Arbor.—December 12, 1919, Board of Commerce. Talk by Mr. Esterline. Attendance about 100.

January 9, 1920, Board of Commerce. Joint meeting of Detroit-Ann Arbor Section of A. I. E. E., Detroit Engineering Society and American Society of Mechanical Engineers. Mr. David Hall, of the W. E. & M. Co., gave a talk, illustrated with lantern slides, on "The Design and Application of Electric Propulsion Equipment for Submarines." Attendance about 150.

Fort Wayne.—December 18, 1919, G. E. Co. Bldg. 26-2. The speaker of the evening was Mr. R. H. Chadwick, G. E. Co., who gave a very interesting talk with demonstrations on "High Frequency Phenomena." The apparatus used was very complete. Attendance 40.

Indianapolis-Lafayette.—December 19, 1919, Chamber of Commerce. Mr. John L. Niesse, Big Four Railway Telephone & Telegraph Engineer, discussed modern railroad wire systems. Attendance 30.

Ithaca.—November 21, 1919, Franklin Hall, Cornell University. Subject: "Measuring Instruments and Other Detail Apparatus in a Large Electrical Power Plant," by Mr. H. S. Baker, Ontario Power Co., Niagara Falls; and "Demonstration of a Curve Drawing Instrument" by Mr. W. B. Stover, of the W. E. & M. Co. Mr. Baker discussed the various detail apparatus and protective devices which are necessary to maintain reliable operation and service in a large electrical generating and distributing system, and gave practical examples from the Ontario Power Plant. Mr. Stover demonstrated the Westinghouse graphic voltmeter, and explained the principle of its operation. Attendance 95.

Los Angeles.—December 2, 1919, Auditorium Los Angeles Polytechnic High School. This was a special meeting with several other technical societies participating. Speaker: Dr. Frank B. Jewett. Subject: "Some War-time Developments in Electrical Communication and Allied Fields." Attendance 900.

December 5th, 1919, Choral Hall, Auditorium Bldg. Dr. Jewett explained the technical problems involved in the developments of electrical communication which were brought up in his lecture at the meeting of December 2. Dr. Jewett answered many questions which had been handed in as a result of the previous meeting. Attendance 180.

Lynn.—December 17, 1919, G. E. Hall. Lecture on "Fundamentals of Economics" delivered by Mr. George E. Roberts, Vice-President, National City Bank, New York. Attendance 298.

January 7, 1920, G. E. Hall. Subject: "Manufacture and Uses of Steel." Speakers: Messrs. W. H. Kaup and T. J. Jobson. Attendance 155.

Madison.—December 16, 1919, Assembly Chamber, Capitol. Illustrated lecture by Professor L. S. Smith, of the University of Wisconsin, on City Planning and Zoning. The paper was followed by a discussion of some of the phases of Madison's proposed zoning law. Attendance 25.

Milwaukee.—December 18, 1919, Athletic Club. Subject: "The beginning of a New Lighting Era, or How Fast Can you See?" Speaker: Mr. S. E. Doane, Chief Engineer, National Lamp Works, G. E. Co., Nela Park, Cleveland, Ohio. The speaker used interesting apparatus and lantern slides to demonstrate what a very important factor in production and industrial progress illumination really is. Attendance 160.

January 14, 1920, Athletic Club. Mr. Max Rotter, Consulting Engineer for the Busch-Sulzer Brothers, Diesel Engine Company, St. Louis, gave a very interesting talk on the Diesel engine with particular reference to the two cycle engines. The talk was illustrated. Attendance 140.

Minnesota.—December 8, 1919. Paper: "Electrical Cooking" by Mr. H. E. Kahlert, of the Minneapolis G. E. Co. The speaker gave a history of the development of electric ranges and a description of the various types of ranges now in use. His paper gave information as to demands, load factor and diversity factor of electric ranges for residence, apartment houses and large users, such as hotels. The meeting was preceded by an electrically cooked dinner. Attendance 51.

Panama.—December 6, 1919, Balboa Heights. Mr. C. J. Welcke, of the Electric Storage Battery Co., New York, read a paper on "Storage Batteries, their Construction and Uses," after which a lively discussion took place. Attendance 31.

December 13, 1919, Balboa Heights. Mr. Holmstrom, of the Automatic Electric Co., Chicago, Ill., gave a talk on the Automatic Telephone. A 25 line P. A. X. switchboard was used for demonstration. Attendance 35.

January 10, 1920, Balboa Heights. Subject: "Symposium on Underground Construction." Discussion led by Mr. William T. O'Connell. Messrs. Hersh, Graham, Bleakley, Moffat and Stiles took part. Attendance 12.

Philadelphia.—January 12, 1920, Engineers Club. Subject: "Electric Propulsion of Ships and Submarines." Speakers: Eskil Berg, G. E. Co., and W. E. Thau, W. E. & M. Co. Attendance 132.

Pittsburgh.—January 12, 1920, Chamber of Commerce Auditorium. Subject: "The Application of Electrical Apparatus to Steel Mills." Speaker: Mr. C. E. Stoltz, W. E. & M. Co. Attendance 68.

Portland.—December 9, 1919, University Club. Mr. O. L. LeFever and Mr. A. D. Leach, of the Northwestern Electric Company, presented papers on "Central Station Steam Heating Problems," Mr. LeFever dealing with high pressure transmission and Mr. Leach with low pressure distribution. Addresses were illustrated with stereopticon. Attendance 19.

Seattle.—November 17, 1919, Chamber of Commerce. Subject: "Some War Time Developments in Communication and Allied Fields." Speaker: Dr. F. B. Jewett. Dr. Jewett illustrated his talk with lantern slides and one reel of motion pictures. Attendance 85.

December 16, 1919, Chamber of Commerce. Paper: "Radio Engineering in the Thirteenth Naval District," presented jointly by Mr. R. H. Marriott and Dr. H. H. Lester of the Bremerton Naval Station Radio Laboratory. Dr. Lester outlined the scope of the work done by this district, explained the fundamental principles and circuits, and showed the desirability of the new trans-Pacific wireless route from Keyport to Vladivostock by way of St. Pauls Island on the coast of Alaska. Mr. Marriott gave a description of a method invented by him for guiding ships into narrow, crooked channels and gave a demonstration with experimental apparatus. The method consisted of passing a small alternating current through a cable laid along the desired course in the channel and determining its location by means of the induction in a coil of 2,000 turns of wire arranged so as to be adjustable. The coil is turned until the maximum induction is obtained as determined by means of head phones, when it points toward the cable. Mr. Jefferson, of Kilbourne & Clark, had a one quarter kilowatt radio set of the commercial type on exhibition and gave a demonstration. The main points brought out in his discussion were the simplicity and ruggedness of the apparatus. Mr. Marriott stated that the current used in his tests was seven tenths of an ampere, which was the maximum amount possible with 40-volts, the rating of the cable used. Following the presentation of the paper election of officers for 1920 was held, resulting as follows: Chairman, Mr. G. E. Quinan, Secretary-Treasurer, Mr. W. T. Batcheller. Attendance 65.

Spokane.—December 18, 1919, Davenport Hotel. Luncheon of the Associated Engineers of Spokane in honor of Messrs. H. V. Winchell and Bradley Stoughton. Mr. Winchell told of earlier visits to the West and Mr. Stoughton discussed the proposed bureau of public works and other engineering matters. Attendance 75.

December 18, 1919, (evening) Davenport Hotel. Regular meeting of the Associated Engineers of Spokane under the auspices of the Columbia Section A. I. M. & M. E. Meeting took the form of a dinner in honor of Messrs. H. V. Winchell and Bradley Stoughton. Attendance 84.

Toronto.—December 5, 1919, Engineers Club. Mr. G. A. Burnham gave a most interesting discourse on Circuit Breakers. He went very thoroughly into the points which affect both the design and the selection of circuit breakers as regards rupturing and current carrying capacity. Mr. Burnham also described in detail a new type of circuit breaker designed to take care of the expansion and release of the gases generated by the arc when the breaker opens under heavy load. A number of slides were shown illustrating the different types of circuit breakers for various capacities and voltages. Attendance 109.

December 19, 1919, Engineers Club. Mr. H. Harvie presented an interesting paper giving a summary of the extent and value of the water powers of Canada. The paper was illustrated by lantern slides showing a number of the undeveloped water powers and also some of the hydro developments at present in operation. In the discussion following the paper Mr. P. W. Ellis, Chairman of the Victoria Park Commission, Niagara Falls, gave some very interesting information relative to the Niagara development and the proposed plans of the Commission for extending the parkway system from Queenston to Lake Erie. Attendance 65.

Washington, D. C.—December 9, 1919, Cosmos Club Hall. Subject: "Methods of Studying the Behavior of Heavy Guns When Fired from a Battleship." Speaker: Dr. H. L. Curtis, of the Bureau of Standards. Illustrated by lantern slides. The talk was followed by a short discussion and an interesting talk by Professor C. A. Adams on research work, standardization and related topics. Attendance 110.

January 13, 1920, Cosmos Club Hall. Commander S. C. Hooper, of the Navy Department, gave an interesting talk on "The Present Status of the Radio Art" illustrated by lantern slides. Attendance 135.

PAST BRANCH MEETINGS

University of Arkansas.—January 13, 1920, Y. M. C. A. Hut. General Electric film shown, entitled "Fairy Magic." Attendance 45.

University of Cincinnati.—January 6, 1920. Mr. W. F. Dunkle, gave a talk on "Smoke and Smoke Prevention." Attendance 65.

Clarkson College of Technology.—January 9, 1920. Reorganization meeting with election of officers as follows: E. R. Taylor, Chairman; H. C. Cohn, Secretary; P. F. Hadlock, Treasurer. Attendance 33.

Clemson College.—January 8, 1920 Elec. Engg. Lecture Rooms. Subject: "The Electron Theory." Discussion by Prof. S. R. Rhodes, J. Y. Dunbar and G. E. R. Davis. Life of Millikan, by T. J. Zeigler. Current Events, C. Yongue. Attendance 59.

University of Colorado.—January 15, 1920. Mr. Robert Owen (a student) gave an illustrated talk on "High Tension Insulating Materials." Three reels of film were then shown covering the use of electrical machinery in the manufacture of steel. Attendance 33.

University of Kentucky.—January 15, 1920, Mechanical Hall. Subjects: (taken from A. I. E. E. PROCEEDINGS) "Speed and Output of Single-Shaft Turbo Generators," D. C. Choate; "Transatlantic Radio Communication," J. W. Coleman, Jr.; "Speed and Output of Single-Shaft Steam Turbines," E. E. Elsey; "California 220,000 volt 1100 mile Transmission Bus," U. V. Garred. Attendance 20.

University of Maine.—January 7, 1920, Lord Hall. Mr. A. B. Moulton related some of his personal experiences with the wireless during the war. Mr. Ames gave a talk on his experiences across with the communication engineers. Both speakers are seniors at college at present. Attendance 27.

Massachusetts Institute of Technology.—January 9, 1920. Subject: "Electric Railway Operation." Speaker: J. H. Neal. Attendance 125.

University of Michigan.—January 14, 1920, Natural Science Bldg. The following films were shown: "Queen of the Waves" and "The Electrical Giant." Attendance 40.

School of Engineering of Milwaukee.—December 17, 1919. Paper: "Appraisals and Evaluations." Speaker : Mr. L. H. Olsen, G. M. of the American Appraisal Company. Attendance 50.

University of North Carolina.—December 1, 1919. Talks as follows: "The Mazda Lamp" F. Weitzel; "Smokeless Powder Loading Plant" R. G. Koontz; "Mercury Interrupters" W. K. Harding; "The Cadillac Motor Car Co. Plant" W. H. Horne. Attendance 40.

University of Notre Dame.—December 1, 1919, Engineering Hall. Papers read as follows: "Transatlantic Radio Communication" by James L. Trant and "The Vacuum Tube" by William L. Wenzel. Attendance 25.

December 15, 1919, Engineering Hall. Illustrated lecture on the Phenomena of Induction by Professor J. A. Caparo; The Life and Works of Ohm by A. B. Butine. Refreshments were served after the meeting. Attendance 27.

Ohio Northern University.—December 17, 1919, Dukes Memorial. Subjects: "Power Switchboard Installing" Mr. R. E. Long, and "Automobile Generator Armature Winding" Mr. Olen Coffman. Attendance 80.

January 8, 1920, Dukes Memorial. Subjects: "House Wiring" Mr. R. E. Long and "The Engineer and the Engineer's Exhibit" Prof. F. F. Turner. Attendance 24.

January 15, 1920, K. of P. Hall. Smoker. Attendance 65.

University of Oklahoma.—December 11, 1919. Subjects: "New Inventions and Discoveries" John P. Jones; "Observations in France" Archie Wallace; "Coil Aerials" E. B. Ferril; "New 50,000 Cycle Alternator" W. A. Kitchen. Attendance 21.

University of Pennsylvania.—November 17, 1919. Paper: "Interior Illumination." Speaker: S. Zuchovitz.

December 1, 1919. Papers: "The Development of the Incandescent Lamp" R. A. Hoke, and "Trunk Line Electrification" R. T. Ervin.

December 15, 1919. Papers: "The Manufacture of Wires and Cables" H. James and "Resuscitation from Electric Shock" W. M. Arthur.

January 12, 1920. Papers: "Vacuum Tubes" W. H. J. McIntyre, and "Starting and Lighting of Automobiles" J. M. Ryan.

Stanford University.—January 7, 1920. Business meeting. Attendance 8.

January 14, 1920. Subject: "The Place of the Engineer in Society." Speaker: Dr. David Starr Jordan. Attendance 50.

Syracuse University.—December 11, 1919. Address by Mr. R. E. Greiner on "Electrical Solutions to Economic Problems." Attendance 14.

December 18, 1919. Address by Mr. K. J. Cole on "Rectifiers." Attendance 12.

January 13, 1920. Moving picture film "The King of the Rails" was shown, following which Mr. G. A. Mezger gave an illustrated lecture on "Electrification of Railroads." Attendance 88.

Throop College of Technology.—December 5, 1919. Subject: "Opportunities in Electrical Communication." Speaker: Dr. Frank B. Jewett. Attendance 35.

December 8, 1919. Subject: "Hydroelectric Developments in California." Speaker: Mr. H. L. Doolittle, Engineer, Southern California Edison Co. Attendance 30.

University of Virginia.—January 8, 1920. Professor Shepherd gave an interesting demonstration of overloading a series generator when supplying a lamp load and motor load, and the consequent periodic reversal of the motor's rotation direction, due to the generator overload condition. Attendance 16.

Yale University.—November 25, 1919. Paper: "Some Practical Experiences of an Engineer." Speaker: Mr. Frederic Cutts, General Manager, G. E. Co., New Haven, Conn.

December 9, 1919. Paper: "Some Problems of the Telephone Engineer." Speaker: Mr. L. F. Morehouse, Equipment Development Engineer, A. T. & T. Co., New York, N. Y.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED JANUARY 9, 1920

ANTHONY, HARVEY M., Head of Dept. of Applied Electrical Engineering, Muncie Senior High School, Muncie, Ind.

ARNOLD, JAMES C., Partner, Arnold & Frankfurt, 202 Crary Bldg.; res., 5906 8th Ave. N. W., Seattle, Wash.

ASHBROOK, ROY B., Telephone Engineer, Southern California Edison Co., Alhambra, Cal.

ASKUE, ALBERT R., Inspector & Cable Tester, Cleveland Electric Illuminating Co., Cleveland; res., 3144 E. Overlook Road, Cleveland Heights, Ohio.

BALFE, JOHN P., Supt., Power House, Yukon Gold Co., Dawson, Y. T., Canada.

BEISWENGER, OTTO L., Chief Electrical Operator, The Goodyear Tire & Rubber Co., Akron, Ohio.

BENTON, P. E., Wireman, Panama Canal, Balboa, C. Z.

BIRK, JOSEPH W., Lieut., U. S. Navy Dept. of Electrical Engg. & Physics, U. S. Naval Academy, Annapolis, Md.

BISHOP, JOHN, Assistant, Hydro-Electric Power Commission of Ontario, 190 University Ave., Toronto, Ont.

*BITNER, RALPH EMERSON, Engineer, Western Electric Co., 463 West St., New York, N. Y.

*BOWEN, WILLIAM C., Electrical Engineer, Power Dept., West Penn Power Co.; res., 5413 Stanton Ave., Pittsburgh, Pa.

*BRAFF, JOSEPH, Engineering Assistant, J. Livingston & Co., 70 East 45th St., New York, N. Y.

BRILL, ARTHUR T., Lieut., U. S. Navy Dept. of Electrical Engg. & Physics, U. S. Naval Academy, Annapolis, Md.

CROUCHLEY, FRANCIS D., Student, General Electric Co., 1030 W. Washington Blvd., Ft. Wayne, Ind.

DAGNALL, CLARENCE H., Instructor in Elec. Engg., Cornell University; res., 204 Fairmount Ave., Ithaca, N. Y.

*DIETZE, EGINHARD, Dept. of Development & Research, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

DIONNE, JOSEPH ALEXANDRE, Engineer (Electrical), Office of Supervisor of Plant, Bell Telephone Co., Montreal, P. Q.

DIXON, JOHN EDMUND, Commercial Engineer, General Electric Co., 1031 Monadnock Bldg., Chicago, Ill.

DUDREY, HOWARD E. A., Electrical Engineer, Union Gas & Electric Co., Cincinnati, Ohio.

*DUREN, GEORGE M., Division Inspector, American Tel. & Tel. Co., 823 Boatmen's Bank Bldg., St. Louis, Mo.

ELLIS, HERBERT W., Engineering Dept., National Lamp Works of G. E. Co., Nela Park, Cleveland, Ohio.

*EVANS, DONALD G., Engineer, Wisconsin Gas & Electric Co., 410 Public Service Bldg., Kenosha, Wis.

FAY, LEON WARREN, Advertising Manager, Century Electric Co., 1827 Pine St., St. Louis, Mo.

FERNANDEZ, FERNANDO, First Substation Engineer, Lake Coleridge Power Plant, Addington Substation, Christchurch, N. Z.

*FISHER, J. CARL, Industrial Power Dept., Consolidated Gas & Electric Co., Baltimore, Md.

*FOWLER, WILLIAM KIRK, JR., Student Engineer, General Electric Co.; res., 26 Eagle Street, Schenectady, N. Y.

*FOX, HAROLD N., Electrical Engineer, Shepard Electric Crane & Hoist Co., Montour Falls, N. Y.

FRASER, CHARLES E., Electrical Inspector, U. S. Navy Dept., Navy Yard; res., 1203 Hancock St., Brooklyn, N. Y.

FUJITA, MORIO, Research Engineer, 4th Section of Electro-Technical Laboratory, Ministry of Communications, Tokyo, Japan.

*GANNETT, DANFORTH K., Telephone Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.

*GETTLIN, ALEX. A., Electrical Engineer, U. S. Cast Iron Pipe & Foundry Co., Burlington, N. J.; res., 2529 N. 30th St., Philadelphia, Pa.

GOODWIN, GEORGE L., Chief Electrician, Ludlow Mfg. Associates, Ludlow, Mass.

GRATWICKE, WALTER, British Aluminum Co., Ltd., 109 Queen Victoria St., London E. C. /4, England.

GRIGSBY, LOGAN C., Power Dept., United Railways Co. of St. Louis, 3869 Park Ave., St. Louis, Mo.

*HAAS, JEROME S., Chief Electrician, Atlantic City Electric Co.; res., 2011 Atlantic Ave., Atlantic City, N. J.

HAGERMAN, JESSE C., Telephone Inspector, Hydro-Electric Power Commission, Bank of Hamilton Bldg., Hamilton, Ont.

*HANCOCK, MRYON S., Designer, Westinghouse Electric & Mfg. Co., E. Pittsburgh; res., 1013 Ross Ave., Wilkinsburg, Pa.

HEMENWAY, EVERETT G., Chief Electrician, Instructor in Gyro Compasses, Navy Electrical School, Hampton Roads, Va.

*HERSKOWITZ, LOUIS, Engineering Dept., Third Avenue Railway System; res., 247 W. 116th St., New York, N. Y.

*HINKLE, ALLEN ELLSWORTH, Designing Engineer, General Electric Co.; res., 68 Brown St., Pittsfield, Mass.

*HOTCHKISS, GROSVENOR, Engineer, Western Union Telegraph Co., 195 Broadway, New York; res., 146 Halsey St., Brooklyn, N. Y.

*HUTH, HERMAN R., Electrical Engineer, Cutler-Hammer Mfg. Co., Milwaukee, Wis.

HYDE, LOUIS H., Student Engineer, General Electric Co.; res., 1030 W. Washington Blvd., Ft. Wayne, Ind.
JAEGER, GEORGE A., JR., Electrician, United Electric Construction Co.; res., 507 West 158th St., New York, N. Y.
KAHANT, CHARLES G., Sales Engineer, Roller-Smith Co., 233 Broadway, New York, N. Y.
*KELLY, JOYCE R., Electrical Engineer, Testing Laboratory, Western Electric Co., 463 West St., New York, N. Y.
*KENDALL, EDWARD N., Telephone Engineer, American Tel. & Tel. Co., 201 Telegraph Bldg., Harrisburg, Pa.
*KISO, DAIJIRO, Engineer, Industrial Division, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
KOIZUMI, MITSUO, Electrical Engineer, Anzan Steel Works, South Manchuria Railway Co., Dairen, Japan.
KONGSTED, LUDVIG P., Designing Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.
LEA, EDWARD, Erecting Electrical Engineer, General Electric Co., Schenectady, N. Y.
LE BEAN, JOHN F., Draftsman, W. H. Taylor & Co.; res., 148 N. 7th St., Allentown, Pa.
LEE, ALEXANDER W. H., Operating Dept., N. Y. Edison Co., 208 W. 85th St., New York, N. Y.
LEUNG, NAI HANG, Assistant Electrical Engineer, West Penn. Power Company, Pittsburgh, Pa.; res., 64 Oxford St., Cambridge, Mass.
LOCKWOOD, JOSEPH B., Senior Operator, Lockport Light, Heat & Power Co., 32 Bacon St., Lockport, N. Y.
MACRAE, F. G., Electrical Engineer, Railway Improvement Co., 61 Broadway, New York, N. Y.
MALONE, JAMES JOSEPH, Supervising Engineer, Postmaster General's Dept., Melbourne, Australia.
MARLEY, GEORGE W., Instrument Tester, Commonwealth Edison Co.; res., 4010 Vincennes Ave., Chicago, Ill.
*MARSTELLER, GEORGE F., 440 Dayton St., Akron, Ohio.
MATTSON, CHARLES O., Electrician, W. & A. Fletcher Company; res., 400 Monroe St., Hoboken, N. J.
MATULICH, LAWRENCE C., Lyndock St., Hyde Park, South Australia, Aus.
MCKEAN, HAROLD S., Electrical Engineer, Canadian General Electric Co., 212 King St. W., Toronto, Ont.
MEADE, THOMAS R., Operator, Sub-station, Puget Sound Traction, Light & Power Company, 4545 California Ave., Seattle, Wash.
*MILLER, FRANK R., Student Engineer, General Electric Co.; res., 415 Brandywine Ave., Schenectady, N. Y.
MORLAN, SAMUEL E., Telephone Representative, Accounting Dept., Mountain States Tel. & Tel. Co., Denver, Colo.
MUNDY, SIDNEY G., Assistant Contract Engineer, Bruce Peebles & Co. Ltd., Edinburgh, Scotland.
MYERS, MORTIMER A., Electrical Engineer, The Maintenance Co.; res., 112 W. 103rd St., New York, N. Y.
NEWTON, ELMER G., Chief Steam & Electric Engineer, Pierce Oil Corp., Sand Springs, Okla.
*NORTON, JOSEPH E., Electrician & Trouble Man, Otis Elevator Co., Boston; res., 1190 Columbus Ave., Roxbury, Mass.
*OLSEN, OLAF M., Electrician, Baltimore & Ohio R. R., Washington, Ind.
*PENDARVIS, HARRY REED, Lieut. (j. g.), U. S. N., Chief Engineer, U. S. S. Porter, Navy Yard, Philadelphia, Pa.
*PETZING, ERWIN W., Telephone Engineering, Western Electric Co., Hawthorne; res., 939 N. Drake Ave., Chicago, Ill.
*PHILIPS, ROBERT C., Salesman, Canadian Westinghouse Co., Ltd., Bank of Hamilton Bldg., Toronto, Ont.
PINCKNEY, GLENN M., Designer, Frederick S. Holmes, 2 Rector St.; res., 481 W. 159th St., New York, N. Y.
POOLE, STAFFORD G., Shift Engineer, Municipal Electricity Works, Peterboro, Eng.
POULTERER, WILLIAM TAYLOR, Elec. Engineer, Electrical Dev. & Machine Co.; Philadelphia Electric Co. Supply Dept., 132 S. 11th St., Philadelphia, Pa.
RANDALL, LAURENCE C., Electrical Engineer, Brooklyn Rapid Transit Co.; res., 199 8th Avenue, Brooklyn, N. Y.
*REAGAN, MAURICE E., Inspector of Elec. Equipment, Kansas City Railways Co., 1500 Grand Ave., Kansas City, Mo.
RILEY, HUGH J., Chief Electrician, Printing Crafts Bldg., 461 8th Ave., New York, N. Y.
*ROBERTS, WALTER VAN BRAAM, Instructor, Princeton University, Princeton, N. J.
ROSENAUER, MOSES B., Instructor in Electrical Laboratory, Boston Trade School, Boston, Mass.
*RUKENBROD, J. K., Tester, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 1308 Kirkpatrick Ave. N., Braddock, Pa.
*RUSSELL, MARSHALL H., Asst. Head, Train Control Test, General Electric Co., Schenectady, N. Y.
SHERMAN, HUGH S., Commercial Electrical Engineer, General Electric Co., St. Louis, Mo.
*SHETZLINE, ROY A., Telephone Engineering, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
*SHORT, PHILIP B., General Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
SINGER, SAMUEL B., Electrical Engineer, Century Electric Co.; res., 5174 Cabanne Ave., St. Louis, Mo.
SMITH, HIRAM G., Piedmont Power & Light Co., Burlington, N. C.
*SMITH, PAUL C., Oscillograph Operator, Test Dept., Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
SPARKS, RAYMOND E., Power Installer, Automatic Electric Co., Winnipeg, Man.
TALMAGE, CHARLES H., Manager, Western Electric Co., 41 W. Broadway, Salt Lake City, Utah.
*TASHIMA, YOSHIO, Asst. Switchboard Engineer, Westinghouse Elec. & Mfg. Co., Markham & Mangum Sts., Atlanta, Ga.
*TESSOHN, ISIDOR M., 948 Union Ave., New York, N. Y.
*THRALL, EDWIN F., Graduate Student, Sheffield Scientific School, Yale Univ., New Haven, Conn.; res., Plaza Hotel, New York, N. Y.
*TOWLE, NORMAN L., Elec. Engg. Dept., Iowa State College, Ames, Iowa.
UMPLEBY, GEORGE F., Elec. Engg. Dept., Consolidated Gas, Electric Light & Power Co., Baltimore, Md.
WARD, H. C., Sales Manager, General Electric Co., 1208 Granite Bldg., Rochester, N. Y.
*WEGMANN, CARL A., Electrician, Central Power Co.; res., 926 Rex Ave. N. E., Canton, Ohio.
WERDEN, EDWARD T., Draftsman, Interborough Rapid Transit Co., 98th St. & 3rd Ave., New York, N. Y.
*WHEELER, HERBERT H., Engineering Asst., Western Union Telegraph Co., 195 Broadway, New York, N. Y.
WHITNEY, ALLAN J., Charge Plant Dept., Whitney Company, 101 Park Ave., New York, N. Y.
WITTMAN, FRANCIS E., Sales Engineer, Canadian Westinghouse Co., 1207 Bank of Hamilton Bldg., Toronto, Ont.
WOOLSTON, LOUIS F. B., Electrical Engineer, General Electric Co., Pierce Bldg., St. Louis, Mo.
WRIGHT, ERNEST M., Electrical Engineer, Pacific Gas & Electric Co., 445 Sutter St., San Francisco, Cal.
ZUBE, HENRY EARNEST, Asst. to Chief Electrician, American Shipbuilding Co.; res., 1311 6th St., Lorain, Ohio.

Total 104

*Former enrolled student.

ASSOCIATES RE-ELECTED JANUARY 9, 1920

HUNT, RAYMOND, General Manager, Tide Water Power Company, Wilmington, N. C.
THERKELSEN, ERIC, Asst. Prof. of Mech. Engineering, Univ. of Montana; res., 716 S. Grand Ave., Bozeman, Mont.
VAN METER, R. H., Electrician, Union Carbide Company, Niagara Falls, N. Y.

MEMBERS ELECTED JANUARY 9, 1920

CREAGER, EDWIN F., Works Manager, Remy Electric Div., General Motor Corp., Anderson, Ind.
SEELY, GARRETT, T., Gen. Manager, Mahoning & Shenango Ry. & Lt. Co., Youngstown, Ohio.

FELLOW ELECTED JANUARY 9, 1920

Recommended for Election by the Board of Examiners, December 8, 1919

PEDERSEN, PEDER OLUF, Prof. of Elec. Engineering, The Royal Technical College, Copenhagen, Denmark.

Transferred to Grade of Fellow January 9, 1920

ALEXANDER, HARRY, Electrical and Mechanical Engineer, New York, N. Y.
ALEXANDERSON, E. F. W., Consulting Engineer, General Electric Co., Schenectady, N. Y.

Transferred to Grade of Member January 9, 1920

BURNHAM, ROY R., Consulting Engineer, Boston, Mass.
CORNEY, CHESTER A., Electrical Engineer, Stone & Webster, Boston, Mass.
DILLON, THEODORE H., Professor of Electrical Engineering, Massachusetts Institute of Technology, Cambridge, Mass.
HOWE, WILLIAM M., First Lieut., Corps of Engineers, U. S. Army, Washington, D. C.
NIKIFOROFF, BASIL, Electrical Engineer, Operating Dept., Alabama Power Co., Birmingham, Ala.
ROBISON, ARCH, Construction Supt., J. G. White Engineering Corp., Marcus Hook, Pa.
SCHMID, ERNEST E., Vice-President and Manager, Shield Electric Co., New York, N. Y.
WOOD, FRANK W., Vice-President and Chief Engineer, Chas. Cory & Son, Inc., New York, N. Y.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at meetings, held in November, 1919, and January, 1920, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

Recommended in November 12, 1919, to Grade of Member

JOHNSTON, A. LANGSTAFF, JR., Lieut. Comdr., U. S. N. R. F., Senior Asst. Inspector of Machinery, U. S. Navy, Newport News. Va.

Recommended in January 1920, to Grade of Fellow

GOLDSMITH, ALFRED N., Professor in Charge of Electrical Engineering, College of the City of New York, N. Y.

To Grade of Member

BEARDSLEY, CLIFFORD R., Electrical Engineer, Fred T. Ley & Co. Inc., Springfield, Mass.

CARROLL, RANDOLPH S., Superintendent, Underground Dept., Portland Railway, Light & Power Co., Portland, Ore.

DUBSKY, FRANCIS, Electrical Engineer, Transformer Engineering Dept., General Electric Co., Pittsfield, Mass.

FOSTER, BENJAMIN P., Electrical Engineer, E. I. Du Pont de Nemours & Co., Wilmington, Del.

HESTON, WALTER C., Industrial Power Engineer, Portland Railway, Light & Power Co., Portland, Ore.

HUNT, RAYMOND, General Manager, Tide Water Power Co., Wilmington, N. C.

LINCOLN, JAMES F., General Manager, Lincoln Electric Co., Cleveland, O.

MORTON, ROBERT B., Electrical Engineer, Toltz King & Day, St. Paul, Minn.

SCHIPPEL, HENRY F., Research Engineer, Ames Holden McCready, Ltd., Montreal, Que.

SOLOMON, NATHAN C., Contracting Electrical Engineer, New York, N. Y.

STRAW, JESSE B., Chief Engineer, The William Gordon Corp., Philadelphia, Pa.

WISEMAN, ROBERT J., Wire and Cable Engineer, National Conduit & Cable Co. Inc., Hastings-on-Hudson, N. Y.

APPLICATIONS FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member objecting to the election of any of these candidates should so inform the Secretary before February 28, 1920.

Adams, Claude H., Detroit, Michigan.
Adams, John R., (Member), Logan, West Virginia.
Adelberg, I. S., Cleveland, Ohio.
Admire, Amzi O., Cleveland, Ohio.
Ahearn, William H., Philadelphia, Pennsylvania.
Andrews, Joseph F., Atlanta, Georgia.
Appleman, Glen, Allentown, Pennsylvania.
Armstrong, Charles H., Atlanta, Georgia.
Armstrong, Vernon D., Seattle, Washington.
Austermiller, Elmer O., Steubenville, Ohio.
Bagby, C. C., Denver, Colorado.
Bain, James W., Montreal, Quebec.
Barnes, Shepard, Buffalo, New York.
Ballinger, John G., Toronto, Ontario.
Beach, Samuel W., Washington, D. C.
Beattie, William P., Norwood, Ohio.
Bechtol, Harvey W., (Member), Cleveland, Ohio.
Bendel, Emil H., San Luis Obispo, California.
Benzon, Axel, Curtis Bar, Maryland.
Bergegrun, Theo., Marion, Ohio.
Bird, Arthur A., Newark, New Jersey.
Biser, Mark H., Washington, D. C.
Blanding, Freeman A., Schenectady, New York.
Boice, William B., Toledo, Ohio.
Bowie, James W., Millbury, Massachusetts.
Bradfield, Joseph M., Atlanta, Georgia.
Bravo, Ricardo S., Jr., (Member), Sugarland, Texas.
Buelhausen, Edgar, Yonkers, New York.
Burgess, William H., Cleveland, Ohio.
Burrage, Claude, Milwaukee, Wis.
Burtzberger, Fred, New York, New York.
Byrd, Alfred A., Montreal, Quebec.
Caffrey, Charles S., Long Island City, New York.
Campbell, James S., Northbridge, Massachusetts.
Canada, William J., Boston, Massachusetts.

BOARD OF EXAMINERS

F. L. Rhodes, Chairman, 195 Broadway, New York.
Murray C. Beebe, H. N. Latey, Wm. S. Murray,
H. H. Norris, E. M. Sawtelle, Clayton H. Sharp,
Wilfred Sykes, H. S. Wynkoop.

SECTIONS COMMITTEE

Walter A. Hall, Chairman, General Electric Co., West Lynn, Mass.
C. Francis Harding, Vice-Chairman, Purdue University, Lafayette, Ind.
F. B. Jewett, H. A. Pratt, J. Lloyd Wayne, 3rd,
and the chairmen of all Institute Sections *ex-officio*.

COMMITTEE ON STUDENT BRANCHES

C. Francis Harding, Chairman, Purdue University, Lafayette, Ind.
Alexander M. Gray, A. C. Lanier, J. C. Parker,
Charles F. Scott.

MEMBERSHIP COMMITTEE

R. W. Krass, Chairman, W. E. & M. Co., 165 Broadway, New York City.
Wills Maclachlan, S. C. Medbery, Jr., G. S. Rose,
G. E. Stoltz,
and the Chairmen of all Membership Committees of Sections.

PUBLIC POLICY COMMITTEE

H. W. Buck, Chairman, 49 Wall St., New York.
C. A. Adams, N. A. Carle, John W. Lieb,
A. C. Marshall, Wm. McClellan, C. E. Skinner.

LAW COMMITTEE

Samuel Sheldon, Chairman, 198½ Schermerhorn St., Brooklyn, N. Y.
John H. Finney, F. B. Jewett, Charles Robbins,
D. B. Rushmore, Charles A. Terry.

HEADQUARTERS COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
William A. Del Mar, F. L. Hutchinson.

U. S. NATIONAL COMMITTEE OF INTERNATIONAL ELECTROTECHNICAL COMMISSION

C. O. Mailloux, President, 20 Nassau St., New York.
F. B. Crocker, Vice-President,
A. E. Kennelly, Secretary, Harvard University, Cambridge, Mass.
Comfort A. Adams, B. A. Behrend, James Burke,
John J. Carty, L. W. Chubb, W. A. Del Mar,
Gano Dunn, H. W. Fisher, H. M. Hobart,
Dugald C. Jackson, B. G. Lamme, W. S. Moody,
Charles Robbins, E. B. Rosa, David B. Rushmore,
Charles F. Scott, Clayton H. Sharp, C. E. Skinner,
S. W. Stratton, Elihu Thomson, R. B. Williamson.

COMMITTEE ON SAFETY CODES

Farley Osgood, Chairman, 80 Park Place, Newark, N. J.
J. C. Forsyth, H. B. Gear, H. O. Lacount,
Johnston Livingston, M. G. Lloyd, R. W. E. Moore,
Henry N. Muller, H. R. Sargent, G. A. Sawin,
A. M. Schoen, George F. Sever, H. S. Warren.

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT

George F. Sever, 4 Divinity Ave., Cambridge, Mass.
C. A. Adams, A. H. Babcock, L. B. Stillwell,
Schuyler Skaats Wheeler.

BOARD'S COMMITTEE ON TECHNICAL ACTIVITIES

Wilfred Sykes, Chairman, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
G. Faccioli, W. I. Slichter.

STANDARDS COMMITTEE

L. T. Robinson, Chairman, General Electric Co., Schenectady, N. Y.
E. J. Cheney, Secretary, Public Service Commission, Albany, N. Y.
P. G. Agnew, G. A. Anderegg, Frederick Bedell,
L. F. Blume, James Burke, G. A. Burnham,
P. H. Chase, H. H. Clark, F. P. Cox,
E. B. Craft, W. A. Del Mar, F. M. Farmer,
H. W. Fisher, F. C. Hanker, H. M. Hobart,
H. H. Humphrey, H. D. James, P. Junkersfeld,
A. E. Kennelly, G. L. Knight, R. W. Krass,
C. O. Mailloux, C. S. McDowell, W. L. Merrill,
Taliaferro Milton, L. F. Morehouse, F. D. Newbury,
H. S. Osborne, S. G. Rhodes, Charles Robbins,
R. F. Schuchardt, C. E. Skinner, A. B. Smith,
John B. Taylor, A. H. Timmerman, W. K. Vanderpoel,
R. B. Williamson.

EDISON MEDAL COMMITTEE

Appointed by the President for terms of five years

Term expires July 31, 1920.
Carl Hering, Chairman, Harris J. Ryan, Robert Lindsay.
Term expires July 31, 1921.
W. C. L. Eglin, Bancroft Gherardi, E. W. Rice, Jr.
Term expires July 31, 1922.
Comfort A. Adams, L. A. Ferguson, S. W Stratton.
Term expires July 31, 1923.
Frederick Bedell, L. T. Robinson, Calvert Townley.
Term expires July 31, 1924.
E. D. Adams, H. H. Barnes, B. G. Lamme.

Elected by the Board of Directors from its own membership for terms of two years.

Term expires July 31, 1920.
Charles Robbins, C. E. Skinner, W. I. Slichter.
Term expires July 31, 1921.
G. Faccioli, W. A. Hall, Wilfred Sykes.

Ex-Officio

Calvert Townley, President, George A. Hamilton, Treasurer,
F. L. Hutchinson, Secretary.

SPECIAL COMMITTEE

COMMITTEE ON DEVELOPMENT

Charles F. Scott, Chairman, Sheffield Scientific School, Yale University, New Haven, Conn.

F. F. Brand, Pittsfield, Mass.	H. E. Bussey, Atlanta, Ga.
J. C. Clark, Stanford University, Cal.	Clem A. Copeland, Los Angeles, Cal.
Ira M. Cushing, Boston, Mass.	R. H. Dalgleish, Washington, D. C.
W. A. Del Mar, New York, N. Y.	F. G. Dustin, Minneapolis, Minn.
H. W. Eales, St. Louis, Mo.	H. S. Evans, Boulder, Colo.
F. R. Ewart, Toronto, Ont.	Baxter R. Grier, Gatun, C. Z.
W. A. Hall, W. Lynn, Mass.	John Harisberger, Seattle, Wash.
W. F. James, Philadelphia, Pa.	V. Karapetoff, Ithaca, N. Y.
Leslie Killam, Milwaukee, Wis.	J. J. Kline, Fort Wayne, Ind.
P. M. Lincoln, Cleveland, O.	Chas. A. Lund, Spokane, Wash.
A. S. MacDowell, Rochester, N. Y.	John C. Parker, Ann Arbor, Mich.
H. T. Plumb, Salt Lake City, Utah.	L. T. Robinson, Schenectady, N. Y.
A. M. Schoen, Atlanta, Ga.	R. F. Schuchardt, Chicago, Ill.
C. H. Schum, Erie, Pa.	W. D. Scott, Portland, Ore.
Samuel Sheldon, Brooklyn, N. Y.	G. E. Snider, Toledo, O.
N. W. Storer, Pittsburgh, Pa.	L. E. Underwood, W. Lynn, Mass.
H. L. Wallau, Cleveland, O.	J. W. Watson, Madison, Wis.
J. Lloyd Wayne, Indianapolis, Ind.	J. B. Whitehead, Baltimore, Md.

TECHNICAL COMMITTEES

ECONOMICS OF ELECTRIC SERVICE

C. S. Ruffner, Chairman, The North American Company, 30 Broad Street, New York.

H. V. Bozell	John B. Fisken,	W. S. Gorsuch,
L. G. Ireland,	A. H. Kruesi,	J. F. Meyer,
S. G. Rhodes,	Allard Smith,	E. H. Sniffen,
	P. B. Yates.	

EDUCATIONAL

J. C. Parker, Chairman, 274 New Engineering Bldg., Ann Arbor, Mich.

C. R. Dooley,	F. F. Fowle,	Charles S. Howe,
C. E. Magnusson,	E. B. Merriam,	L. F. Morehouse,
G. H. Pfeiff,	H. W. Price,	R. F. Schuchardt,
W. I. Slichter,	William R. Work.	

ELECTRICAL MACHINERY

B. A. Behrend, Chairman, 200 Devonshire St., Boston, Mass.

James Burke,	Alexander Churchward,	A. M. Dudley,
C. E. Eveleth,	G. Faccioli,	B. G. Lamme,
A. C. Lanier,	R. B. Williamson.	

ELECTROCHEMISTRY AND ELECTROMETALLURGY

F. A. J. FitzGerald, Chairman, FitzGerald Laboratories, Niagara Falls, N. Y.

F. F. Ambuhl,	E. R. Berry,	Joseph L. Dixon,
I. R. Edmands,	L. E. Imlay,	F. A. Lidbury,
W. R. Whitney,	J. L. Yardley.	

ELECTROPHYSICS

F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.

P. G. Agnew,	H. D. Arnold,	E. F. Burton,
L. W. Chubb,	J. C. Clark,	C. P. Eldred,
E. P. Hyde,	Chester W. Rice,	C. E. Skinner.

INDUSTRIAL AND DOMESTIC POWER

A. G. Pierce, Chairman, 2003 Farmers Bank Bldg., Pittsburgh, Pa.

P. H. Adams,	E. V. Buchanan,	H. W. Cope,
Wm. E. Date,	James Dixon,	A. M. Dudley,
R. H. Goodwillie,	H. D. James,	W. C. Kalb,
R. H. McLain,	E. H. Martindale,	A. H. Timmerman,
L. E. Underwood,	H. Weichsel,	R. B. Williamson.

INSTRUMENTS AND MEASUREMENTS

S. G. Rhodes, Chairman, 104 E. 32nd St., New York.

C. W. Baker,	Wm. M. Bradshaw,	H. B. Brooks,
F. P. Cox,	F. V. Magelhaes,	Charles Robbins,
	Clayton H. Sharp.	

IRON AND STEEL INDUSTRY

W. F. James, Chairman, 1442 Widener Building, Philadelphia, Pa.

F. B. Crosby,	F. D. Egan,	Gordon Fox,
Eugene Friedlaender,	E. S. Jefferies,	W. C. Kennedy,
D. M. Petty,	Wm. T. Snyder,	Wilfred Sykes,
R. B. Williamson,	Fred H. Woodhull,	J. D. Wright.

LIGHTING AND ILLUMINATION

C. E. Clewell, Chairman, University of Pennsylvania, Philadelphia, Pa.

G. N. Chamberlin,	J. R. Cravath,	Terrell Croft,
N. S. Dickinson,	Bassett Jones,	F. D. Newbury,
P. G. Nutting,	R. C. Powell,	E. B. Rosa,
W. D'A. Ryan,	W. M. Skiff,	G. H. Stickney.

MARINE

Arthur Parker, Chairman, New York Shipbuilding Corp., Camden, N. J.
L. C. Brooks, Secretary, Bethlehem Shipbuilding Corp., Bethlehem, Pa.

R. A. Beekman,	Eskil Berg,	A. R. Cheyney,
Maxwell W. Day,	E. G. Gallagher,	H. L. Hibbard,
W. F. James,	C. A. Jones,	C. S. McDowell,
W. P. Meschenmoser,	I. H. Osborne,	G. A. Pierce, Jr.
J. B. Porter,	L. B. Sinclair,	H. M. Southgate,
Wilfred Sykes,	W. E. Thau,	A. E. Waller
	F. W. Wood.	

MINES

W. A. Chandler, Chairman, H. C. Frick Coke Co., Scottsdale, Pa.

R. T. Andrae,	F. H. Armstrong,	Graham Bright,
L. C. Ilsley,	R. L. Kingsland,	A. B. Kiser,
Wills Maclachlan,	E. B. Woodward.	

POWER STATIONS

Philip Torchio, Chairman, 124 E. 15th St., New York.

J. T. Barron,	A. E. Bauhan,	E. T. Brandon,
H. W. Eales,	W. L. R. Emmet	W. S. Gorsuch,
H. P. Liversidge,	I. E. Moultrop,	Frank D. Newbury,
H. S. Putnam,	R. F. Schuchardt,	Russell W. Stovel
H. L. Wallau.	R. B. Williamson.	

PROTECTIVE DEVICES

D. W. Roper, Chairman, 72 West Adams Street, Chicago, Ill.

G. E. Armstrong,	P. H. Chase,	W. H. Cole,
E. E. F. Creighton,	H. W. Eales,	F. C. Hanker,
E. M. Hewlett,	F. L. Hunt,	P. MacGahan,
D. A. McKenzie,	A. A. Meyer,	L. C. Nicholson,
N. L. Pollard,	F. E. Ricketts,	Charles Robbins,
T. C. Taliaferro,	H. R. Woodrow.	

TELEGRAPHY AND TELEPHONY

Donald McNicol, Chairman, 253 Broadway, New York.

O. B. Blackwell	R. E. Chetwood	E. H. Colpitts
H. W. Drake,	W. B. Kouwenhoven,	L. F. Morehouse,
R. W. Osborne,	W. O. Pennell,	L. M. Potts,
S. A. Rhodes,	A. B. Smith,	D. M. Therrell,
W. H. Winter,	D. E. Wiseman.	

TRACTION AND TRANSPORTATION

W. S. Murray, Chairman, Room 2800, 165 Broadway, New York.

A. H. Babcock,	Reinier Beeuwkes,	R. H. Dalgleish,
W. G. Gordon,	John Murphy,	W. B. Potter,
Ralph H. Rice,	Guy A. Richardson,	C. S. Ruffner,
N. W. Storer,	H. M. Warren.	

TRANSMISSION AND DISTRIBUTION

Edward B. Meyer, Chairman, Public Service Electric Co., Newark, N. J.
J. E. Woodbridge, Vice-Chairman, 58 Sutter St. San Francisco, Cal.

R. W. Atkinson,	A. O. Austin,	Wallace S. Clark,
W. H. Cole,	A. W. Copley,	M. T. Crawford,
E. E. F. Creighton,	F. E. Ricketts,	D. W. Roper,
C. S. Ruffner.	R. F. Schuchardt,	A. E. Silver,
	W. K. Vanderpoel.	

INSTITUTE REPRESENTATIVES

AMERICAN BUREAU OF WELDING

W. L. Merrill.

AMERICAN COMMITTEE ON ELECTROLYSIS

Bion J. Arnold, Wm. S. Murray, F. N. Waterman.

AMERICAN ENGINEERING STANDARDS COMMITTEE

Comfort A. Adams, H. M. Hobart. C. E. Skinner.

AMERICAN YEAR-BOOK ADVISORY BOARD

Edward Caldwell.

BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY.

L. T. Robinson, Samuel Sheldon. Calvert Townley.

COMMISSION OF WASHINGTON AWARD

John Price Jackson, Charles F. Scott.

COUNCIL OF AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

H. H. Humphrey, John B. Taylor.

ENGINEERING COUNCIL

Comfort A. Adams, H. W. Buck, N. A. Carle,
E. W. Rice, Jr., C. E. Skinner.

ENGINEERING FOUNDATION BOARD

Frank B. Jewett, E. W. Rice, Jr.

FRANCO-AMERICAN ENGINEERING COMMITTEE

A. M. Hunt L. B. Stillwell.

JOHN FRITZ MEDAL BOARD OF AWARD

Comfort A. Adams, H. W. Buck, Calvert Townley
E. W. Rice, Jr.

JOINT COMMITTEE ON ENGINEERING EDUCATION

Charles F. Scott, Samuel Sheldon.

JOINT COMMITTEE ON STANDARD THREAD FOR INSULATORS AND INSULATOR PINS

J. T. Barron.

LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle,
Samuel Sheldon, W. I. Slichter.

NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

The chairman of the Institute's Committee on Safety Codes.

NATIONAL JOINT COMMITTEE ON OVERHEAD AND UNDERGROUND LINE CONSTRUCTION.

Farley Osgood, Percy H. Thomas.

NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

C. A. Adams, Frank B. Jewett, W. R. Whitney.

NAVAL CONSULTING BOARD

Benjamin G. Lamme, Frank J. Sprague.

SPECIAL JOINT COMMITTEE ON DETERMINATION OF POWER FACTOR IN POLYPHASE CIRCUITS

P. G. Agnew, F. Conrad, F. P. Cox, F. C. Holtz, A. E. Kennelly, Farley Osgood, S. G. Rhodes.

U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION

A. E. Kennelly, C. O. Mailloux, Clayton H. Sharp.

LOCAL HONORARY SECRETARIES

Charles le Maistre, 28 Victoria St., London, S. W., England.
Guido Semenza, N. 10 Via S. Radegonda, Milan, Italy.
Robert Julian Scott, Christchurch, New Zealand.
T. P. Strickland, 61 Hunter St., Sydney, N. S. W.
W. G. T. Goodman, Adelaide, South Australia.
James S. Fitzmaurice, Adelaide, South Australia.
L. A. Herdt, McGill Univ., Montreal, Que.
Henry Graftio, Ministry of Ways of Communication, Petrograd, Russia.
A. S. Garfield, 10 Rue de Londres, Paris, France.
Harry Parker Gibbs, Tata Hydroelectric Power Supply Co., Ltd., Bombay, India
John W. Kirkland, Johannesburg, South Africa.

The Last Stand of the Reciprocating Steam Engine

BY A. H. ARMSTRONG

Chairman Electrification Committee, General Electric Company

During the year 1920 the people of the United States will pay out for automobiles, not commercial trucks or farm tractors, but pleasure vehicles, a sum of money considerably greater than the estimated requirements of our steam railways for that year. The railways however, may find it very difficult and perhaps impossible to secure the large sums needed without government aid, notwithstanding the fact that the continued operation and expansion of our roads are of vital necessity to the welfare and prosperity of the country and all its industries. The will of the American public has always been constructive and undoubtedly, in due time, its voice will be heard and properly interpreted by its representatives in Washington with the resulting enactment of such laws as will permit our railways again to offer an attractive field for the investment of private capital.

The purpose of this paper is not to discuss the politics of the situation nor any necessary increase in freight rates that may be required to make our roads self-sustaining, but rather to offer certain suggestions as to the best manner of spending the sums that must ultimately be provided for new construction and replacements.

During the war period many lessons have been most clearly brought home to us and not the least of these is that there is something inherently wrong with our steam railroads. During the three generations of its development, we have become accustomed to look upon the steam engine as properly belonging to the railway picture and have given little thought to its wastefulness and limitations. It is around the steam locomotive that railway practise of today has gradually crystallized.

During the winter of 1917-18 our railways fell down badly when the need for them was the greatest in their history. It is true that the cold weather conditions were unprecedented and the volume of traffic abnormal but the weaknesses of the steam engine haulage were disclosed in a most startling and disastrous manner. Delayed passenger trains in cold weather can be endured by the traveling public in suffering silence or voluble expression, according to temperament; but the blocking of our tracks with frozen engines and trains, resulting in a serious reduction of tonnage in cold weather and a prohibitive delay in transportation of freight in times of great stress, is quite another thing and plainly indicates the inability of the steam engine to meet overloads and adverse climatic conditions.

In marked contrast to the adjourning steam engine divisions, the 440-mile electrified section of the Chicago, Milwaukee and St. Paul Railway continued to do business as usual all through that trying winter of 1917-18. The electric locomotives brought both freight and passenger trains over the electrified tracks in schedule time or better; in fact, it was quite customary to make up on the 440-mile electric run fully two hours of the time lost by passenger trains on adjoining steam engine divisions. While the results obtained upon the Chicago, Milwaukee & St. Paul were perhaps more spectacular due to the greater mileage electrically equipped, other electrified roads contributed similarly attractive records. The reliability and permanency of the comparison between steam and electric locomotive haulage is sufficiently guaranteed, therefore, by the results of several years' operation, to justify drawing certain conclusions regarding the merits of the two types of motive power. The following analysis of the railway situation is therefore offered for the purpose of exposing the fact that railroading today is in reality steam engine railroading and the general introduction of the electric locomotive will permit fundamental and far reaching changes being made in the method and cost of hauling freight and passenger trains.

The writer is not proposing the immediate electrification of all the railways in the United States, as many roads of lean tonnage would render no adequate return upon the large capital investment required, but is offering the following table of total operating statistics simply as a measure of the magnitude of the problem confronting us in the future. In this country it should be noted, however, that we have during the past thirty years installed electric power stations equal to twice the estimated capacity required for the electrical operation of every mile of our tracks today.

The tonnage passing over the tracks of our railways may be subdivided in a most interesting manner as shown in Table I.

TABLE I

TOTAL TON-MILE MOVEMENT

All Railways in United States—Year 1918

	Per cent	Ton miles
1—Miscellaneous freight cars and contents...	42.3	515,000,000,000
2—Revenue coal cars and contents..........	16.23	197,000,000,000
3—Locomotive revenue, driver weight only..	10.90	132,300,000,000
4—Passenger cars, all classes..............	16.13	196,000,000,000
Total revenue, freight and passenger...	85.56	1,040,300,000,000
5—Railway coal..........................	5.00	60,600,000,000
6—Tenders, all classes......................	6.50	78,800,000,000
7—Locomotive railway coal................	0.39	4,700,000,000
8—Locomotive, non-driving weight.........	2.55	31,000,000,000
Total non-revenue...................	14.44	175,100,000,000
GRAND TOTAL (All classes)......	100	1,215,400,000,000

The first four items, representing 85.56 per cent of the total ton-miles made during the year 1918, may be regarded as fundamentally common to both steam and electric operation. By introducing the electric loco-

Presented at the Schenectady Section of the A. I. E. E., February 20, 1920.

motive, however, the last four items are reduced to the extent of completely eliminating items (6) and (7), reducing item (5) by possibly 80 per cent and item (8) by one-half. Of the total of 14.64 per cent affected, therefore, it may be assumed for purposes of comparison that approximately 12 per cent or 146,000,000,000,ton-miles at present hauled by steam engines over our roads will be totally eliminated with electric locomotive haulage. This ton-mileage eliminated is equal to over 20 per cent of items (1) and (2) representing the revenue producing freight traffic on our railways. In other words, if all our railways were completely electrified they could carry one-fifth more revenue producing freight tonnage with no change in present operating expenses or track congestion.

It is evident that the greater part of the tonnage reduction effected by electrification is included in items (5) and (6), representing the railway coal movement in cars and engine tenders. The steam engine tender will of course entirely disappear, while the railway coal haulage will be largely curtailed by utilization of water as a source of power and the establishment of steam power houses as near coal mines as an abundant supply of good condensing water and load demand will permit. While the water power should be utilized to the fullest economical extent, the greater portion of the railway power must undoubtedly be supplied by coal, due to the unequal geographical distribution of water power available.

Even with coal as a source of power, it may not be fully appreciated just how enormous is the saving made by burning fuel in large modern power stations under the most efficient conditions possible, instead of under the boilers of 63,000 engines which by necessity must be designed and operated for service rather than for fuel economy. During the year 1918 the fuel used by the railways is reported to be shown in Table II.

TABLE II

RAILWAY FUEL 1918

Total coal production (all grades)	678,211,000 tons
Used by steam railways	163,000,000 tons
Percentage of total	24 per cent
Total oil marketed in U. S.	355,927,000 bbl.
Used by steam railways	45,700,000 bbl.
Percentage of total	5.8 per cent
Coal equivalent of oil at 3½ bbl.	13,000,000 tons
Total equivalent railway coal	176,000,000 tons

A quarter of all the coal mined in the United States is consumed on our railways and the following analysis will point out some features of this extreme wastefulness which are inseparable from steam engine operation.

During the year 1910, exhaustive tests were made upon the Rocky Mountain Division of the C., M. & St. P. Ry. to determine the relation existing between the horse power hours work done in moving trains and the coal and water consumed on the steam engines in service. Table III gives the results of these tests:

TABLE III

C., M. & ST. P. RY.; ROCKY MOUNTAIN DIVISION

Coal and Water Used

	Water per h.p-hr.	Water per lb. coal	Coal per h.p-hr.
Three Forks-Piedmont	39.6	5.08	7.75
Piedmont-Donald	35.4	4.70	7.54
Deer Lodge-Butte	39.7	4.85	8.31
Butte-Donald	40.4	4.86	8.74
Harlowton-Jenny	38.0	4.09	8.90
Jenny-Summit	44.2	4.65	9.48
Three Forks-Piedmont	41.4	6.51	6.37
Piedmont-Donald	40.2	5.63	5.78
Average of eight tests	39.86	5.04	7.86

The records were obtained during the portion of the runs that engines were doing useful work in overcoming train and grade resistance, that is, all standby losses were excluded. The through run, however, included such losses in the magnitude shown in Table IV:

TABLE IV

STANDBY LOSSES

	Coal per hour
Fire banked in roundhouse	150 lb.
Cleaning fires for starting	800 lb.
Coasting down grade	950 lb.
Standing on passing track	500 lb.

Adding standby losses to the average of 7.86 lb. per horse power hour obtained in the preceding eight tests the total actual coal consumed under the engine boiler in twenty-four hours divided by the actual work performed by the engine is found to be 10.18 lb. per horse power hour at the driver rims.

As the result of this particular series of tests it was determined that the coal consumed while doing useful work was raised 30 per cent by standby losses. It should be appreciated in this connection moreover that this value was obtained on through runs with no yard switching service or adverse climatic conditions. It may be concluded therefore that under all conditions of service fully one-third of the coal burned on our steam engines today is absolutely wasted in standby losses of the general nature indicated above.

Supplementing these tests, a 30-day record was kept of all the coal used on the entire Rocky Mountain Division and the total engine, tender, and train movement reduced to horse power hours, resulting in a value of 10.53 lb. coal consumed per horse power hour at the driver rims. Both of the above values were based upon constants of 6 lb. per ton train resistance at all speeds and 0.7 lb. per ton per degree of curvature as determined in part by dynamometer car tests and representative of general railway operation. Reducing the average coal values of the test runs and the 30-day record per

horse power hour to electrical constants, we arrive at the data shown in Table V:

TABLE V

COAL EQUIVALENT PER KW-HR.; STEAM OPERATION

Coal per h.p.-hr. at driver rims	10.27 lb.
Coal per kw-hr. at driver rims	13.75 lb.
Coal per kw-hr. at power supply on basis 55 per cent efficiency	7.56 lb.

It is this last figure of 7.56 lb. of coal burned on steam engines to get the equivalent tonnage movement of one kilowatt-hour delivered from an electric power station that is of special interest to this discussion. Comparing coal and electrical records on the Butte, Anaconda & Pacific Railway before and after electrification results in arriving at the value of 7.17 lb. of coal previously burned on the steam engines to equal the same service now performed by one kilowatt-hour input at the substations, a figure comparing favorably with 7.56 lb. above arrived at by an entirely different method.

TABLE VI

ANALYSIS OF ROUNDUP COAL USED

Fixed carbon	49.26 per cent
Volatile carbon	38.12 per cent
Ash	7.74 per cent
Moisture	4.88 per cent
B.t.u.	11899

Making the due allowance for the fact that roundup coal is somewhat low in heat units, it is nevertheless within the limits of reasonable accuracy to assume that the steam engines operating over all our railways are consuming coal at a rate closely approximating 12.75 lb. per kilowatt-hour of useful work done, as measured at the driver rims or 7 lb. per kilowatt-hour as measured at a power station and including for convenience of comparison the transmission and conversion losses inherent to electrical operation.

An electric kilowatt can be produced for so much less than 7 lb. of coal that we are now in position to finally forecast the approximate extent of the coal economy that would result from electrification.

TABLE VII

RELATION BETWEEN KW-HR. AND TON-MILES CHICAGO, MILWAUKEE & ST. PAUL RAILWAY

Avery-Harlowton

Year 1918

	passenger	freight
Average weight locomotive	300 ton	284 ton
Locomotive miles, 1918	651,000	1,431,500
Locomotive ton-miles	195,000,000	407,000,000
Trailing ton-miles	434,406,000	2,903,099,000
Total ton-miles	629,406,000	3,310,049,000
Kilowatt-hours	24,890,000	105,287,000
Watthours per ton-mile	39.6	31.9
Ratio Locomotive to Total	31 per cent	12.3 per cent
Watthours per ton-mile combined movement	33.2	
Ratio locomotive to total combined movement	15.25 per cent	

All power values in Table VII are given at the point of supply from the Montana Power Company at 100,000 volts and include deductions made for the return of power due to regenerative braking of the electric locomotives on down grades, amounting to approximately 14 per cent of the total. Owing to the excessive rise and fall of the profile of the electrified zone of the C., M. & St. P. Ry., its operation is materially benefited by regenerative electric braking and the value of 33.2 watthours per ton mile for combined and passenger movement should possibly be raised to the round figure of 40 to make it apply more nearly to conditions universally obtaining on more regular profiles.

Hence referring again to the ton-mile values of Table I:

Total ton-miles, 1918	1,215,400,000,000
Watthours ton mile	40
Kw-hr. total movement	48,700,000,000
Coal required at 7 lb. per kw-hr.	170,000,000 ton

The actual equivalent coal consumed on our steam railways for the year 1918 is given as 176,000,000 tons, closely approximating the figure of 170,000,000 tons estimated above from the operating results obtained on the C., M. & St. P. electrified zone. These several values check so closely as to justify the completion of the fuel analysis of the railways as shown in Table VIII:

TABLE VIII

COAL SAVING BY ELECTRIFICATION

Total ton-miles steam	1,215,400,000,000
Reduction by electrification	146,000,000,000
Total ton-miles electric	1,069,400,000,000
Kw-hr. electric at 40 watts	42,776,000,000
Coal on basis 2½ lb. per kw-hr.	53,500,000 tons
Equivalent railway coal 1918	176,000,000 tons
Saving by electrification	122,500,000 tons

The startling conclusion arrived at is that approximately 122,500,000 tons of coal, or more than two thirds the coal now burned in our 63,000 steam engines, would have been saved during the year 1918 had the railways of United States been completely electrified along lines fully tried out and proved successful today. This vast amount of coal is 50 per cent greater than the pre-war exports of England, and twice the total amount consumed in France for all its railways and industries. Moreover, the estimate is probably too conservative as no allowance has been made for the extensive utilization of water power which can be developed to produce power more cheaply than by coal in many favored localities.

Perhaps no nation can be justly criticized for lavishly using the natural resources with which it may be abundantly provided. In striking contrast with the picture of fuel waste on the railways in this country however is the situation presented in Europe at this writing.

Faced with a staggering war debt, with two millions of its best men gone and an undetermined number incapacitated for hard labor, and with so much reconstruction work to do, France has to contend also with the destruction of half its coal producing capacity. Before the war, France imported twenty-three million of

the sixty-five million tons of coal consumed. It is estimated that the full restoration of coal mines in the Lens region will take ten years to accomplish, which means materially increasing the coal imported into France if pre-war consumption is to be reached, as the relief rendered from the Saar District will not compensate for the loss on productivity of the mines destroyed by the Germans. This situation is being promptly met in part by France in the appointment of a Commission to study the feasibility of the general electrification of all its railways with special reference to immediate construction in districts adjacent to its three large water-power groups, the Alps, the Pyrenes, and the Dordoyne or Central plateau region. It is proposed to electrify 5200 miles of its total of 26,000 miles of railways during a period covering twenty years. If this work is accomplished at a uniform rate of 260 miles a year, it is a most modest program considering the extreme necessity for the improvement.

In even worse plight is Italy with practically no coal of its own and compelled to import its total supply of 9,000,000 tons. The war has brought home to these countries what it means to be dependent upon imported fuel for their very existence and both Italy and Switzerland are also proceeding with extensive plans for railway electrification. Contrary to the general understanding, the mines of Belgium are not destroyed, but the need of fuel economy is very acute and this country also has broad plans for railway electrification with immediate construction in view.

Recognizing the many advantages of electric operation of its railways, Europe furthermore considers this a most opportune time to start the change rather than to spend its limited funds in replacing worn out and obsolete steam equipment in kind. Also in marked contrast to the American attitude is the sympathetic interest and constructive assistance rendered by the Governments abroad in regard to the vital matter of rehabilitation of its railway systems. It would not be without precedent if the next decade witnessed England and the Continent outstripping this country in the exploitation of another industry which, while possibly not conceived here, has certainly been more fully developed and perfected in America than elsewhere.

From figures given, the conclusions in Table IX are arrived at in the matter of power station capacity required for complete electrification of the railways in the United States.

TABLE IX

RAILWAY POWER REQUIRED

Kw-hr. electric operation, 1918	42,776,000,000 kw-hr.
Average load, 100 per cent load-factor	4,875,000 kw.
Power station capacity at 50 per cent load-factor	9,750,000 kw.

It appears therefore that approximately 10,000,000 kw. power station capacity would have been sufficient to run all the railroads for the year 1918, or one-half the station capacity which has been constructed during the past thirty years.

TABLE X

ESTIMATED POWER STATION CAPACITY UNITED STATES YEAR 1918

Central stations	9,000,000 kw.
Electric railways	3,000,000 kw.
Isolated plants	8,000,000 kw.
Total	20,000,000 kw.

In the order of magnitude, therefore, it is not such a formidable problem to consider the matter of power supply for our electrified railways and it becomes evident also that the railway power demand will be secondary to industrial and miscellaneous requirements.

Such being the case, the question of frequency of electric power supply becomes of great importance, if the full benefit is to be obtained from extensive interconnected generating and transmission systems covering the entire country. Indeed with the full development of interconnected power systems supplying both railway and industrial load from the same transmission wires, the above assumption of 50 per cent load-factor for the railway load can be materially bettered.

In this connection a method of limiting the troublesome peak load hitherto considered inherent to railway power supply has been in successful operation on the electrified C., M. & St. P. zone for the past year. With unrestrained peaks, the load-factor was approximately 40 per cent, but this low value has been raised to nearly 60 per cent by the installation of an inexpensive and most satisfactory device known as the power limiting and indicating apparatus.

TABLE XI

LOAD-FACTOR RECORDS C., M. & ST. P. RY.

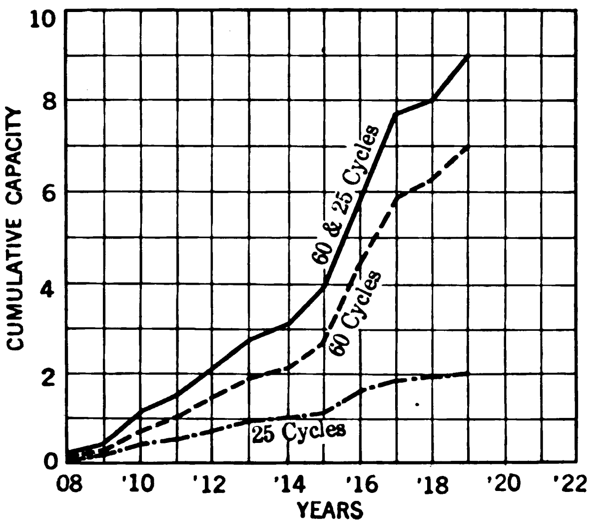
1919

	Per cent duration of peak	Per cent load-factor
April	6.4	59.3
May	4.6	56.1
June	1.6	56.5
July	0.7	55.6
August	9.5	58.8
September	4.1	54.7

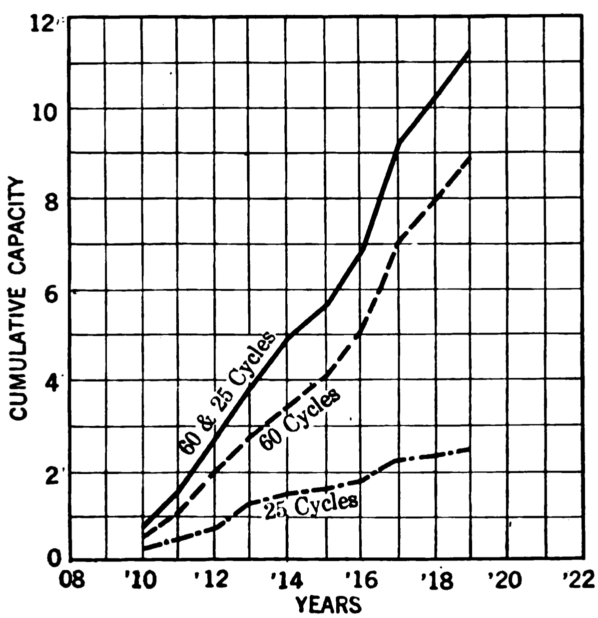
The readings of Table XI cover the performance on the 220 miles of the Rocky Mountain Division supplied by seven substations controlled as a unit. A load-factor of nearly 60 per cent brings the electric railway within the list of desirable customers and makes it possible for power companies to quote attractively low rates for power.

Returning again to the question of power supply, it is instructive to note the general trend toward a higher frequency as evidenced by the turbine and transformer sales of the General Electric Company during the past decade.

It is quite evident that 60 cycles is rapidly becoming the standard frequency in America; and many instances are on record where it has replaced lower frequencies, principally 25 cycles. This fact in no manner handicaps the future development of electric railways, as entirely satisfactory power can be obtained from 60-cycle transmission lines through synchronous converters or synchronous motor-generator sets, depending upon the



Comparative Sales of 60 and 25-Cycle Turbines



Comparative Sales of 60 and 25-Cycle Transformers

Fig. 1

direct-current trolley voltage desired. Indeed a growing appreciation of the declining importance of 25-cycle power generation in this country contributed largely to the demise of the single-phase system, as its chief claim for recognition is wiped out with the introduction of the motor-generator substations required with 60-cycle supply.

While America apparently has adopted 60 cycles as its standard frequency and can look forward to unlimited interconnection of its large power systems, European practise is evidently crystalizing on 50 cycles. The situation abroad is as yet, however, not clearly defined. In such a small compact country as Switzerland for instance, where so much electrical development is taking place, there is much conflict of frequencies. Apparently there is little appreciation of the advantages resulting from interconnected power stations; in fact the Loetschberg Railway is supplied with power from 15-cycle waterwheel-driven generators placed in the same power station with 42-cycle units supplying industrial load while in the same immediate district there is a 50-cycle transmission line and no tie-in frequency changer sets as yet installed to interconnect any two frequencies. The power company, power consumer and electrical manufacturer pay heavily for the complication imposed by maintaining three frequencies where only one is needed, and growing appreciation of this fact may lead to the standardization of 50 cycles in Switzerland and thus swing that country in line with its neighbors and ultimately bring about a more economical ratio of installed generator capacity to average load demand for the country as a whole.

A good example of the necessity for improvement in power distribution conditions in Switzerland is provided in the supply of power to the Loetschberg Railway as illustrated in Table XII.

TABLE XII

POWER SUPPLY TO THE LOETSCHBERG RAILWAY

March, 1919

Total for month	540,180 kw-hr.
Average of six 15-min. peaks	3,489 kw.
Load-factor, basis 24 hours	20.8 per cent

As the railway was operating for only seventeen hours per day, the load-factor during actual operation is somewhat better than 20.8 per cent. On the other hand, the actual momentary peak load greatly exceeded 3489 kw.; and this very fluctuating railway load furnishes a good illustration of the need of combining it with other diversified loads, in order to keep down the fixed investment of power station equipment now set aside for this isolated railway load. For example, the 60 per cent load-factor of the C., M. & St. P. power demand is the ratio of average to momentary peak while the Loetschberg Railway peak load is determined by six 15-min. peaks with momentary peaks greatly in excess of this figure.

Apparently the adoption of a standard frequency of 50 cycles would meet all general requirements in Switzerland, but would necessitate the installation of frequency-changing substations to meet the demands for 15-cycle, single-phase railway power. If the electrified railways are to be benefited therefore from the establishment of a common generating and transmission system in Switzerland, the choice of the single-phase railway system might possibly be considered unfortunate, viewed in the light of modern development in

power economics and the successful adaptation of the less expensive and more flexible direct-current motor to high trolley voltages.

From the power station standpoint, the electrification of our railways admits but one conclusion. We have some 63,000 engines now in operation and their average combined load amounts to approximately four million horse power at the driver rims or only an insignificant total of 65 h.p. for each engine owned. It is true that, owing to the shopping and to one cause or another, a large proportion of these engines are not in active service at all times, still the average twenty-four hour output of each engine is less than 10 per cent of its rating. In the case of the C., M. & St. P. electrification the average load of each individual electric locomotive is only 15 per cent of its continuous rating, but by supplying power to 45 electric locomotives from one transmission system, the average combined load-factor is raised to nearly 60 per cent, a figure which could even be surpassed on roads of more regular profile. Furthermore when the railway load is merged with the lighting and industrial power of the district and the whole diversified load supplied from the same 60-cycle transmission and generating system, it is quite evident that all conditions are most favorable for the efficient production of power. In this country such an achievement will probably be governed by the laws of economic return upon the capital required because our vast natural fuel resources are properly regarded as inexhaustable, but in Europe there is the compelling spur of stern necessity behind the movement to utilize economically the water powers they possess in place of the coal they cannot get.

Fig. 2—Twin Views Central Terminal—"Before and After"

While the much discussed subject of power generation and transmission is a very vital part of the railway electrification project, chief interest centers in the electric locomotive itself. Few realize what a truly wonderful development has taken place in this connection in a comparatively few years and how peculiarly fitted this type of motive power is to meet the requirements of rail transportation. Free from the limitations of the steam boiler, and possessing in the electric motor the most efficient and flexible known means of transmitting power to the driving axles, the electric locomotive gives promise of revolutionizing present steam railway practise when its capabilities become fully recognized. The only limits placed upon the speed and hauling capacity of a single locomotive are those imposed by track alignment and standard draft rigging. Only questions of cost and expediency control the size of the locomotive that can be built and operated by one man, as there are no mechanical or electric limitations that have not been brushed aside by careful development. Just what this means in advancing the art of railroading is as yet but faintly grasped, no more than the boldest prophet of twenty years ago could have fully pictured the change that has taken place at the Grand Central Terminal as the result of replacing steam by electricity.

Progress in utilizing the capabilities of the electric locomotive have been slow. It is hard to break away from life-long railway traditions established by costly experience in many cases. In consequence the electric locomotive has thus far simply replaced the steam engine in nearly similar operation. Even under such conditions of only partial fulfillment of its possibilities the electric locomotive has scored such a signal operating success as to justify giving it the fullest consideration in future railway improvement plans.

On the C., M. & St. P. Ry. 42 electric locomotives have replaced 112 steam engines and are hauling a greater tonnage with reserve capacity for still more. On this and other roads, electrification has set a new standard for reliability and low cost of operation. In fact, although no official figures have yet been published, it is an open secret that the reductions in previous steam operating expenses on the C., M. & St. P. Ry. are sufficient to show an attractive return upon the twelve and a half millions expended for the 440 miles of electrification, without deducting the value of the 112 steam engines released for service elsewhere. As the

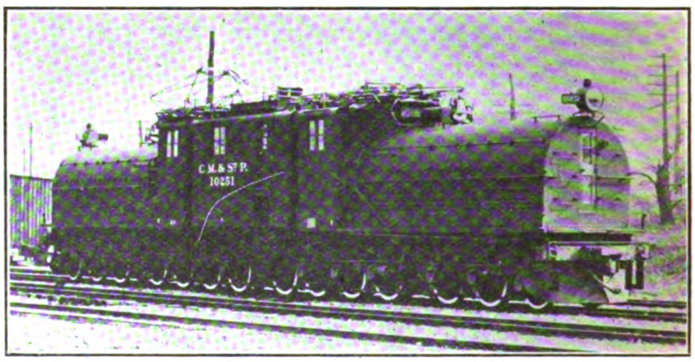


Fig. 3—Chicago, Milwaukee and St. Paul Gearless Locomotive

electric locomotive is destined to leave its deep impression upon the development history of our railways, it is fitting that the remainder of this paper should be devoted to its consideration.

Our steam engine construction is unsymmetrical in wheel arrangement, must run single ended, and is further handicapped with the addition of a tender to carry its fuel and water supply. The result has been much congestion at terminals; and the necessary roundhouses, always with the inevitable turn tables,

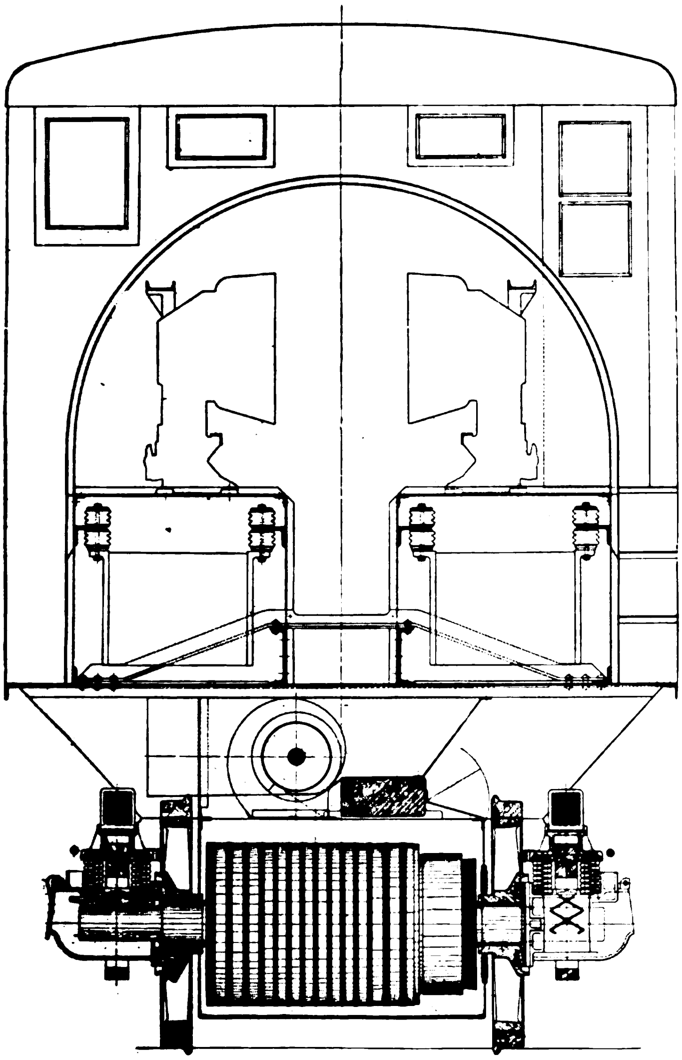

Fig. 4—End Elevation Showing Motor-Line Drawing—C., M. & St. P. Gearless Locomotive

ash pits, and coal and water facilities, have occupied much valuable land; and in addition steam operation has greatly depreciated the value of neighboring real estate. The contrast offered by the two large electric terminals in New York City is too apparent to need more than passing comment, and similar results may be expected on the fulfillment of plans for electrifying the Chicago terminals.

While it has been a simple matter to design electric locomotives to run double ended at the moderate speed required in freight service, the problem of higher speed attainment, exceeding 60 miles an hour, has presented greater difficulties. The electric motor is however so adaptable to the needs of running gear design that electric locomotives are now in operation which can meet all the requirements of high-speed passenger-train running. These results, also, are obtained with less than 40,000 lb. total weight, and 9500 lb. non-spring borne or "dead" weight on each driving axle, and finally, but not least, with both front and rear trucks riding equally well, a success never before achieved in locomotives of such large capacity.

In connection with the riding qualities of electric locomotives, it is of interest to note the conclusions that the Committee of the American Railway Engineering Association, F. E. Turneaure, Chairman, reached in their report of 1917.

From the results of the tests on the electrified section of the Chicago, Milwaukee & St. Paul Railway, the tests made in 1916 on the Norfolk and Western, and the few tests made in 1909 at Schenectady, N. Y., it would appear to be fairly well established that the impact effect from electric locomotives is very much less than from steam locomotives of the usual type. Comparing

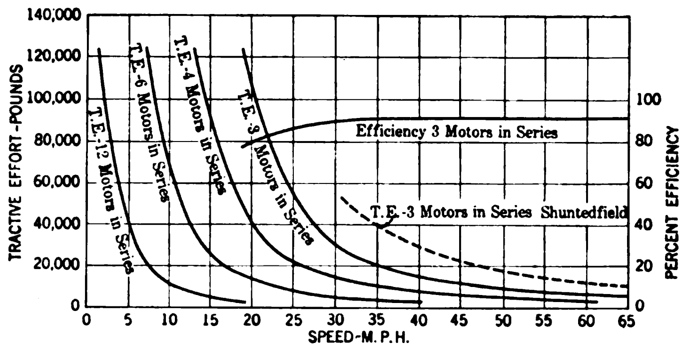

Fig. 5—Characteristic Curves 3000-Volt D-C. Gearless-Motor Locomotive—For C., M. & St. P. R. R.

results obtained in these tests with the results from steam locomotives, it would appear that the impact from electric locomotives on structures exceeding, say, 25 ft. span length, is not more than one-third of the impact produced by steam locomotives.

There is as yet no general acceptance of a standard design of electric locomotive. Geared side-rod construction for heavy freight service and twin motors geared to a quill for passenger locomotives appear to find favor with the Westinghouse-Baldwin engineers, while the General Electric Company goes in for the simple arrangement of geared axle motor for freight and gearless motors for passenger locomotives. In both Switzerland and Italy the side-rod locomotive enjoys an almost exclusive field. How much of this preference for side-rod construction is due to the restrictions imposed by the use of alternating-current motors is hard to determine, but the facts available indicate both in this country and abroad the uniformly higher cost of repairs of this more complicated form of mechanical drive.

The electric railway situation in Italy is further complicated by the employment of three-phase induction motors with all the attendant handicaps of double

overhead trolleys, low power-factor, constant speeds, and overheating of motors resulting from operation on ruling gradients with motors in cascade connection. In many respects the non-flexible three-phase induction motor is poorly adapted to meet the varied requirements of universal electrification; and in consequence Italian engineers are still struggling with the vexing question of a system, which may however be in a fair way of settlement through the adoption of a standard of 50 cycles as the frequency of a nation-wide interconnected power supply, thus throwing the preponderance of advantages to high-voltage direct current.

The extreme simplicity of the gearless motor locomotive appeals to many as does its enviable record of low maintenance cost, reliability, and high operating efficiency, as exemplified by its unvarying performance in the electrified zone of the New York Central for the

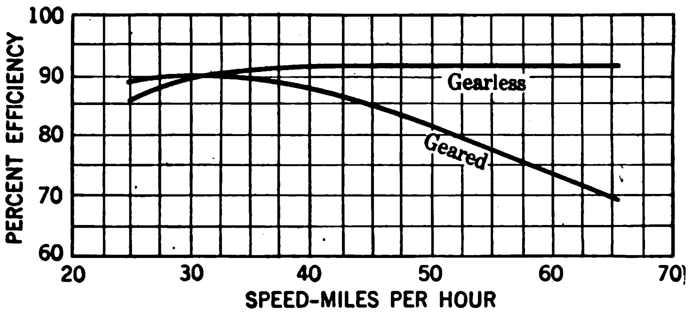

FIG. 6—EFFICIENCY CURVES PRESENT GEARED AND NEW GEARLESS C., M. & ST. P. LOCOMOTIVES

past twelve years. Table XIII shows that the high cost of living did not appear to have reached this favored type of locomotive until the year 1918.

TABLE XIII
MAINTENANCE COSTS NEW YORK CENTRAL

	1913	1914	1915	1916	1917	1918
Number locomotives owned	48	62	63	63	73	73
Average weight, tons	118	118	118	118	118	118
Cost repairs per locomotive mile	4.32	4.03	4.45	3.78	4.01	6.26

The records on the C., M. & St. P. locomotive are equally remarkable when considering their greater weight and the more severe character of service.

TABLE XIV
LOCOMOTIVE MAINTENANCE COSTS CHICAGO, MILWAUKEE & ST. PAUL RAILWAY

	1916	1917	1918
Number locomotives owned	20	44	45
Average weight, tons	290	290	290
Cost repairs per locomotive mile	8.21	9.62	10.87

In both these instances the cost of repairs approaches closely to three cents per 100 tons of locomotive weight. Giving due credit to the excellent repair shop service rendered in each case, it is instructive to note that three cents per 100 tons maintenance cost of these direct-current locomotives is less than half the figures given for any of the alternating-current locomotives operating in the United States or in Europe.

Compared with the cost of repairs for equivalent steam engines, the above figures for electric locomotives are so very favorable as to justify the general statement that electric motive power can be maintained for approximately one-third of the cost of that of steam

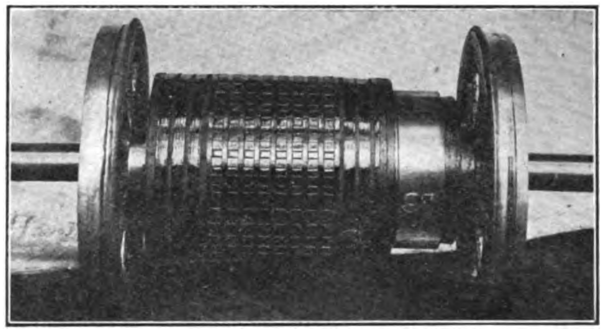

FIG. 7—GEARLESS ARMATURE AND WHEELS

engines for the same train tonnage handled. As locomotive maintainance is a measure of reliability in service and in a way expresses the number of engine failures, it is quite in keeping with the records available to state also that the electric locomotive has introduced a new standard of reliability that effects material savings in engine and train crew expense as well.

While the first cost of electrification is admittedly high, it may in certain instances be the cheapest way to increase the tonnage carrying capacity of a single

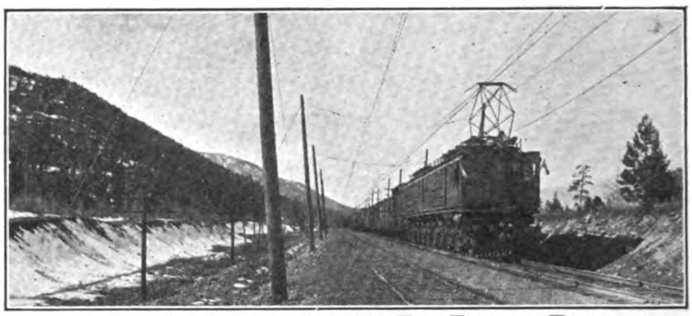

FIG. 8—C., M. & ST. P. 5000-TON FREIGHT TRAIN

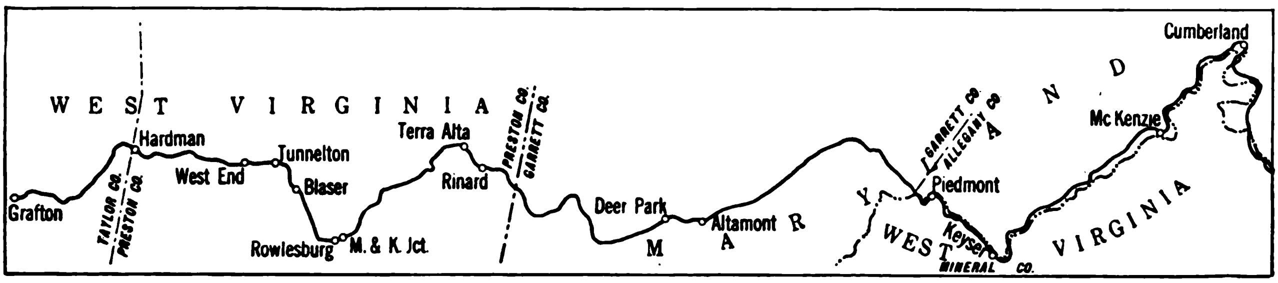
track especially in mountain districts where construction is most expensive and steam engine operation is most severely handicapped. In this connection a comparison of steam and electric operation on the C., M. & St. P. Ry. may be summarized as follows:

For the same freight tonnage handled over the Rocky Mountain Division, electric operation has effected a reduction of 22½ per cent in the number of trains, 24.5 per cent in the average time per train, and has improved the operating conditions so that nearly 30 per cent more tonnage can be handled by

electric operation in about 80 per cent of the time it formerly took to handle the lesser tonnage by steam engines. This means a material increase in capacity of this single-track line which may be conservatively estimated in the order of at least 50 per cent and probably more. In other words, on this particular road, electrification has effected economies which sufficiently justify the capital expenditure incurred and furthermore has postponed for an indefinite period any necessity for constructing a second track through this difficult mountainous country.

Further instances could be cited where the benefits of electrification are badly needed and many of these are fails to respond to our advancing needs. Electrification affords a cheaper and better means of securing increased track capacity and improved service than by laying more rails and continuing the operation of still more steam engines in the same old wasteful way.

To conclude the startling picture of our present railway in efficiency, we are today wasting enough fuel on our steam engines to pay interest charges on the cost of completely electrifying all the railways in the United States, fuel that Europe stands in sad need of and which England and Germany, the pre-war coal exporting countries, cannot now supply. With operating expenses mounting to 82 per cent of revenue, inadequate



B. & O. R. R.—Cumberland Division
Cumberland to Grafton

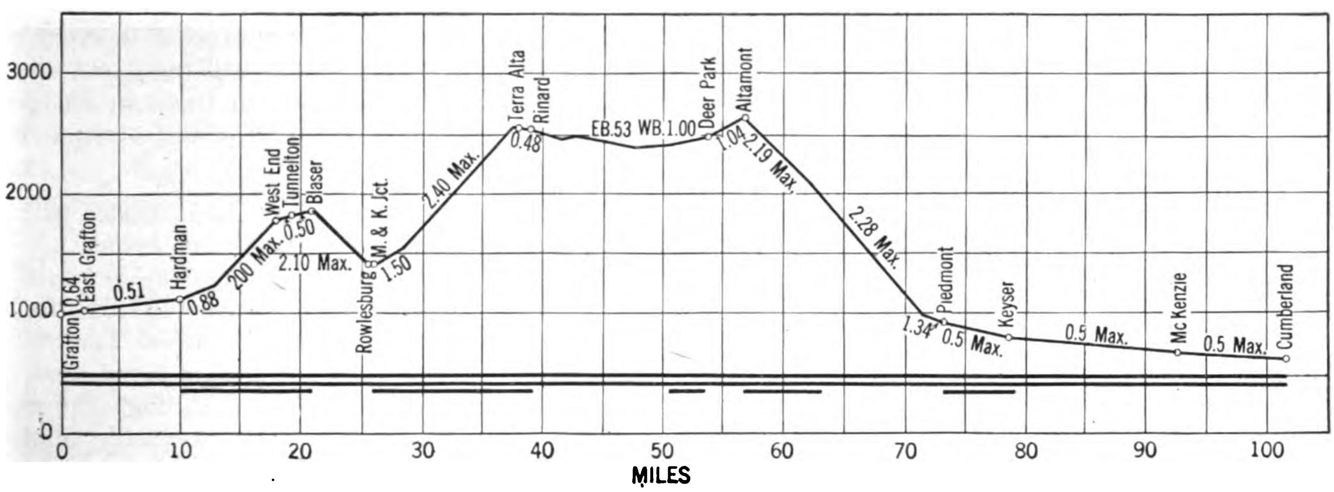


Fig. 9
West End Cumberland Division—Baltimore & Ohio Railroad
Condensed Profile—Showing Ruling Grades

coal-carrying roads, among which the Virginian Railway stands out conspicuously as a good opportunity to make both a necessary improvement and a sound investment.

Reviewing the progress made in a short twenty-year period, we have seen the steam turbine and electric generator drive the reciprocating engine from the stationary power field. The same replacement is now taking place on our ships, big and small, notwithstanding the fact that the marine reciprocating engine is a very good engine indeed and operates under ideal conditions of steady load and constant speed. And now the steam locomotive must in turn give way to the electric motor for the same good reason that the reciprocating steam locomotive has become obsolete and equipment and congestion of tracks, what we need, in addition to constructive legislation and real co-operation on the part of the Government in the matter of rates and safeguarding invested capital, is wise direction in the expenditure of the large sums that must speedily be found and used to bring our railways abreast of the times. Accord full honor to the reciprocating steam engine for the great part it has played in the development of our railways and industries, but complete the work by replacing it with the electric motor and enter upon a new era of real railroading, not restricted steam engine railroading.

A careful study of the seriously congested tracks of the Baltimore and Ohio Railroad between Grafton and Cumberland disclosed vitally interesting facts.

Company coal movement in coal cars and engine tenders constituted over 11 per cent of the total ton-miles passing over the tracks. In other words, due to the very broken profile of this division, the equivalent of one train in every nine is required to haul the coal burned on the engines. Taking advantage of this

FIG. 10—NEW YORK CENTRAL LOCOMOTIVE—LATEST TYPE

fact and the higher speed and hauling capacity of the electric locomotive and its freedom from delays due to taking on water and fuel, it is estimated that the three tracks now badly congested with present steam engine tonnage could carry 80 per cent more freight with electric locomotive operation. The coal output of the

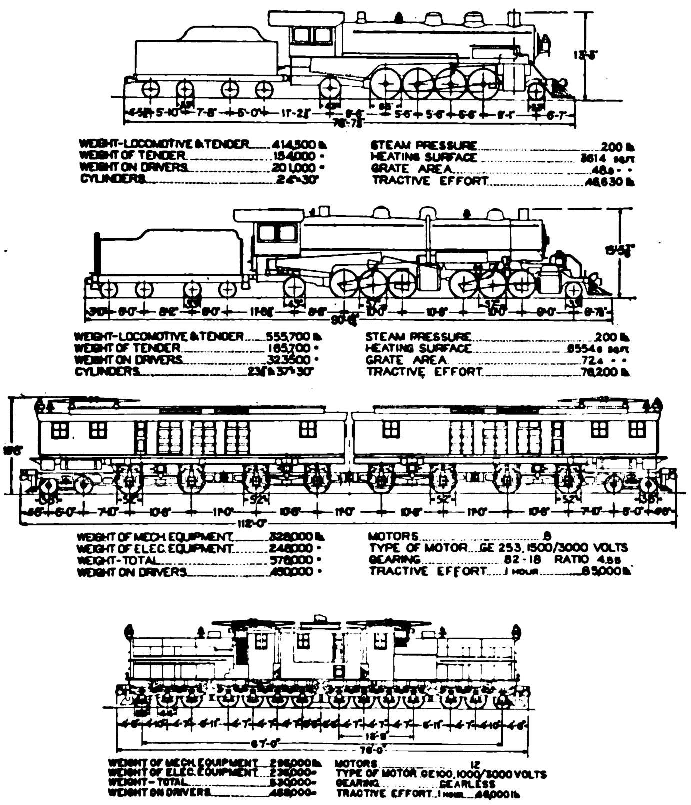

FIG. 11

Fairmount District is largely restricted by the congestion of this division of the B. & O. R. R. and it is probable that equal relief with continued steam engine operation could not be secured without the expenditure of a much larger sum for additional track facilities than would be needed to put electric locomotives upon the present tracks.

PROPOSED METRIC LEGISLATION

Agitation has again been started on the subject of the Government's use of the metric system. The bill covering the proposed plan has not been introduced to date during this session of Congress. It is contemplated that a bill similar to the last metric system bill may be introduced in the near future. It is understood that the proposed legislation will not be put into final form until after the Patents Committee has considered a brief of the arguments in opposition to be submitted by the American Institute of Weights and Measures. If in the light of these arguments it is still found feasible to push such legislation a hearing will probably be given interested parties. The last hearing on this subject was held about fifteen years ago, although the bill in a slightly different form has appeared before practically every session of Congress since that time.

Some few interests have aligned themselves in support of this measure, but it is expected that much opposition will be brought from the manufacturers of the country during the hearings, because it is realized that although the bill may provide for the adoption of a metric system in only the Departments of the Government, the eventual change-over, which would be sure to come, would be a tremendous expense to every phase of industry. The opposition will point out the fact that with industry and foreign trade in its feverish condition the country can ill afford such a radical change.

No doubt but that you have been flooded with congratulations on the success of the JOURNAL,—Your task is a great one, and you may even feel that your pay is small, but no one can estimate the value that such a publication will be to the Electrical Fraternity as the days go by. You may rest assured that your efforts will receive their reward through the greater service the JOURNAL will be to the vaster number of men who will read it.

The issue is just as it should be and I assure you that men will contribute to a live JOURNAL like that, who before would turn a cold ear to any such appeal.

Thanking you again most heartily for the results you have achieved, and the obstacles that you have overcome, I am, BYRON T. MOTTINGER,

Philadelphia, Pa.

Allow me to congratulate the Institute on the appearance of the JOURNAL. I feel sure that after the members of the Institute become accustomed to the new size, it will be universally approved.

CHAS. R. RIKER, Pittsburgh, Pa.

I am much pleased with the new JOURNAL of the A. I. E. E. It will be particularly useful to teachers and students of electrical engineering, as well as to practicing engineers.

A. S. HILL, Orono, Me.

Economical Supply of Electric Power

For the Industries and the Railroads of the Northeast Atlantic Seaboard

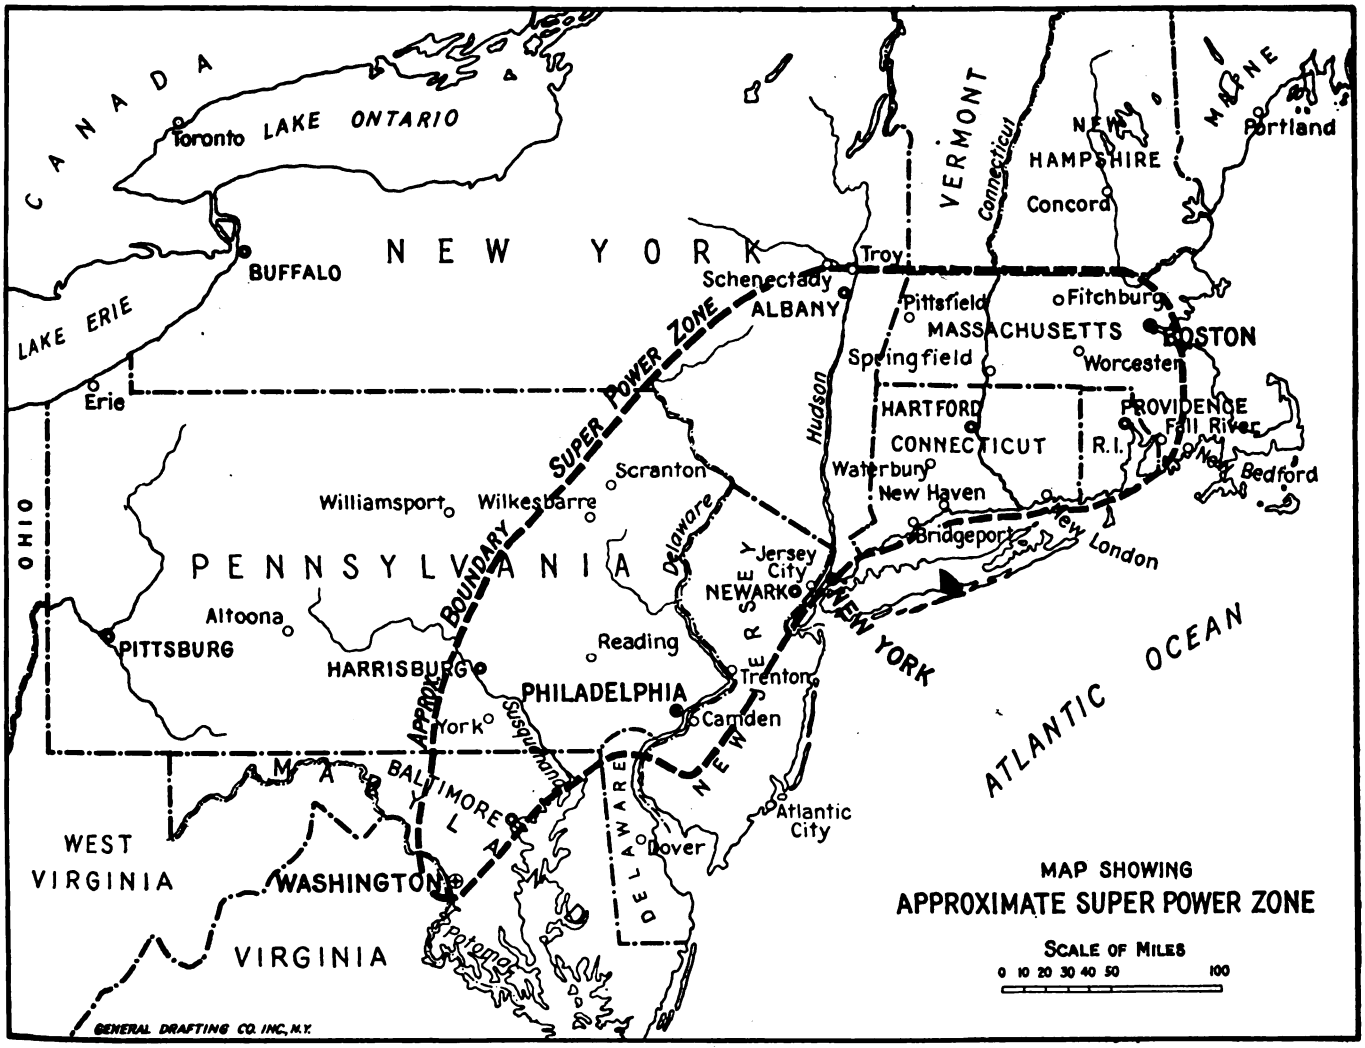
BY W. S. MURRAY

Consulting Engineer, New York City

Contributions to Symposium by:

(1) W. Le R. EMMET, Consulting Engineer, General Electric Co.
(2) J. F. JOHNSON, Engineer Turbine Department, Westinghouse Machine Co.
(3) H. G. REIST, A. C. Engineering Dept., General Electric Co.
(4) F. D. NEWBURY, Manager, Power Engineering Dept., Westinghouse Elec. & Mfg. Co.
(5) W. B. POTTER, Chief Engineer, Railway and Traction Dept., General Electric Co.
(6) PHILIP TORCHIO, Chief Electrical Engineer, New York Edison Co.
(7) PERCY H. THOMAS, Consulting Electrical Engineer, New York City.
(8) W. D. A. PEASLEE, Electrical Engineer, Jeffry-Dewitt Insulator Co.
(9) A. O. AUSTIN, Chief Engineer, Ohio Insulator Co.

THE super-power plan, briefly summarized, provides a means by which a present estimated machine capacity of 17,000,000 horse power—divided 10,000,000 for industrial purposes and 7,000,000 for the railroads—in a region between Boston and Washington and inland from the coast 100 to 150 miles, now operating with a load factor not exceeding 15 per cent, can be lifted to a load factor of greater than 50 per cent and possibly to 60 per cent, and a means by which, conservatively speaking, one ton of coal will do the work of two, and the railroads within the above zone, and those carrying coal into that zone will be relieved of transporting one-half the amount of coal required for power and lighting purposes. In short, the value of machine capacity from a utilization standpoint will be increased three to fourfold, and coal resources for the purposes named conserved twofold.



Presented at the Midwinter Convention of the A. I. E. E., New York, February 19, 1920.

This means that a present plant capacity of 17,000,000 horse power can be replaced by one of not greater than 5,500,000 horse power, and that not less than 30,000,000 tons of coal per annum can be saved, which at $5.00 a ton will represent $150,000,000 a year.

Besides the above savings, two great departments of economy will be created; one applying both to the railroads and the industries, in the reduced cost of maintenance of machinery, and the other applying to the railroads alone, in the reduction of train miles, by virtue of this plan permitting consolidation of trains with resultant savings in train miles. It is estimated that these latter economies will effect a saving of another $150,000,000 annually thus making a total saving of $300,000,000.

The above are the direct savings as estimated from data collected from actual past operations of the specific order contemplated to be put into force in the zone under consideration.

The railroad situation in this country is too well known to hold any brief upon it in this paper. Not secondary to the concern of those private interests from whom the money has come to build and maintain them is that, now, of the people to whom their service means so much. Forgetting for the moment the much-mooted question as to who will own and control them, we cannot afford however, from a national standpoint, irrespective of ownership, operation or control, to overlook any means, large or small, which will be conducive toward reducing expense keeping the standard of American transportation upon its past high plane, and which will operate to hold the roads solvent.

This plan offers immediate relief from the present intolerable congestion by automatically increasing rail capacity without increasing track mileage. It also operates to reduce power equipment investment to å minimum. By the creation of an overhead common carrier system of power the present cargo space now required for industrial coal will be cut in half; train equipment in all classes will have its service factor doubled, and the present steam power equipment, replaced by electrical equipment, can be transferred to other divisions, where it is so vitally needed.

The super-power plan has lately been given much space in the pages of the technical and public press, and except to say that it contemplates the general application of electricity wherever economically possible in the factories and on the railroads, in the zone described, it will not be necessary to add length to this paper by a more detailed description. It will doubtless engage your interest however, to know the following facts:

1. The plan has the unanimous endorsement of Engineering Council representing the American Institutes of Electrical, Mechanical, Civil and Mining Engineers.

2. It has been presented to and unanimously endorsed by the

a. Western Massachusetts Engineering Association
b. Bridgeport Chamber of Commerce
c. Connecticut Chamber of Commerce

3. It is now in Committee with the U. S. Chamber of Commerce, and so far as I know has found only favor in their considerations for the amount of time they have been able to give it among their many other deliberations.

4. Among the many prominent men with whom I have had opportunity to discuss it, including U. S. Senators and Representatives, Engineers, Central Station Operators and Railroad Officials, and Financiers, all have expressed the keenest interest in it.

5. An appropriation of $250,000 forms a part of the sundry civil bill to provide the money necessary to an investigation, under the direction of the Department of the Interior. This investigation will be followed by a report allocating the losses incident to labor and material by virtue of the present inefficient form of power production and distribution with recommended procedure, to cause their elimination.

While satisfied in my own mind that the true economy of power production, and its distribution in this great industrial and railroad field lies in an organized power policy, it is far more important that we should hear the opinions of those men to whom is largely due the great advances of electricity's application. Therefore, the following letter addressed to Messrs. Emmet, Johnston, Reist, Newbury, Porter, Storer, Torchio and Thomas will explain itself:

(I would add that the address referred to in this letter is one which was delivered to the Connecticut Chamber of Commerce and is reprinted in the JOURNAL of the A. I. E. E. for January 1920).

It has been said that the clash of rival systems has delayed the electrification of railroads. This, in my opinion, is true; but I question whether such a result, after all, has not been beneficial.

Fifteen years has been the period over which we have had opportunity to analyze the theory and practise of railway electrification.

Had we known fifteen years ago what we know today about electrification, and therefore could have decided the proper system to apply to each case, the financial stress under which the railroads were laboring would have prevented electrification.

Today the industrial demand for power has grown so prodigiously that faced with the old methods of power production which we have been perpetuating, we find ourselves faced with two factors, greatly militating against securing and maintaining supremacy in world's trade. Viz.: (1) throttled production, and (2) waste of the nation's natural resources.

The past fifteen years of education have opened the eyes of the "opposing camps" to certain fundamental factors which will now permit a prompt unanimity of opinion regarding what system applies. The railroad managers have in the past justly taken the ground that since we could not make up our minds which system was correct, they would wait until we could. But, as stated before, I believe that finance and not system has been the real cause of lack of action on the part of the railroads to electrify and that the delay has been truly beneficial since we can now stand on more solid ground for decision.

I am enclosing copy of an address made before the Connecticut Chamber of Commerce, November 19th, 1919.

While the super-power line as described in that address is an important adjunct to the plan proposed, the central idea is the indorsement of central station expansion through means of which national production may be increased and the conservation of our natural resources made secure.

As the major demand for power in the territory between Boston and Washington is for industrial purposes, I believe that I will be supported in the following conclusion:

(a) That prime generating machinery should be three-phase.

(b) That the power to be applied to railroads should be through synchronous motor generators with the synchronous motor fields designed to relieve to a maximum degree the direct current excitation of the prime generating machinery.

(c) That the question of whether train propulsion be by direct or by alternating current should be settled purely upon the economic relations existing between the generating side of the motor-generator substations and the driving wheels of the motive power. In saying this I realize that this robs the single-phase system of the argument to which it has justly laid claim by virtue of the higher efficiency of static versus rotative substations.

Railroad electrifications, in the past, have been individual to themselves. Today I believe that you will agree that they will form only a part of a whole and indeed be a smaller part, the industrial load being the greater—both receiving power from the same source.

I would like to be first under the above conditions in recognizing two serious limitations to single-phase generation.

(a) Size of generators.

(b) Low power-factor regulation.

The Paper's Committee have assigned the 18th of February during the Midwinter Convention in New York as the date for the presentation of a composite paper bearing upon the subject as presented in the accompanying pamphlet.

It is respectfully requested that you, as expert authorities in the design and application of the apparatus in your respective fields, keeping in mind the central idea of zone application of power, contribute your ideas, and while doing so, eliminate all thought of the past battle of systems.

I further believe that you will agree that the hour has struck for a united front and that such a paper will help the advance of electricity's rightful use in the industrial and railway field.

Since writing this letter contributions have been asked from Messrs. Peaslee and Austin, and their valuable opinions touching upon line and insulation form a part of this presentation.

To write a symposium of the contributions forming the principal part of this paper is at once both a delightful and easy task for there treads through such an effort the supporting element of unanimity of opinion. I shall not undertake to comment individually upon these authors' opinions, for that would be but a discussion of their papers. I will rather treat the subject as a whole, shaping its individual parts from the contributed opinions of the authors, using some cement of my own for coherence, and thus, I trust, arrive at a true composite summary.

I am immediately struck by what might be termed the composite voice of these authors. It is as though they say in unison, "We are ready and the conditions are ready to put this thing together." It is opportune here to quote from the address delivered by Past President Charles F. Scott before the New England Section of the National Electric Light Association, September 24, 1919: "The water powers which Nature has bestowed upon New England will be wastefully used until our best engineering abilities combine them into one great regional power system." Again, "The goal is the super-power system, the interconnection of hydraulic and steam stations—a single comprehensive power system, and the universal use of electric power"; and again, "A still larger view shows the power problem from New York to Washington to be closely related to that of New England. High-voltage transmission makes the region from Portland and Boston on the North to Baltimore and Washington on the South a single electrical area. The wide and more varied the field, the more favorable the diversity factor. Power plants at water powers, at coal mines and on tide-water at the cities, combined into one system insure the highest economy in power production."

Professor Scott shows by undeniable records of past growth of central stations, that if the present rate of increase is maintained in New England, its power requirement, now 1,500,000 kw. will be 5,500,000 kw. in ten years. What is true of New England is true throughout all the centralized industrial and railroad districts of the United States. The super-power system now so urgently needed here in the northeast will find demand elsewhere and related in time of application to the industrial and railroad density of the regions to be considered.

We have indeed come to the realization that electricity solved the problems of high-speed economic production and has become the agent of a tremendously diversified utilitarianism. I heard a representative of one of the larger electrical companies say he had just closed an order for a million motors for electrical washers. Think of this as a million kilowatt, and then think also of the diversity factor of such a load! This is but one illustration. The electric range, the toaster, curling iron—all these little implements depending upon electricity, integrate great power loads upon central stations. The amount of power a one-kw. washer takes in an hour would move a 40-ton freight car half a mile. Insignificant as the individual power application may be, their combination makes the central force to drive them immense.

Mr. Emmet more than confirms the statements made to the Connecticut Chamber of Commerce relative to the great economy of electric over steam locomotives and draws deserved attention to the more reliable operating characteristics of the electric engine over that of the steam during the winter months. Traction requirements in such season "go up" and the electric locomotive's capacity automatically "goes up" to meet them, while the steam locomotive's capacities when they are most needed "go down." Who has not had the experience when upon a steam train during bitter cold weather, of having his question,

"What's the matter?" answered by the conductor, "We can't make steam."

Mr. Emmet's contribution, though brief, not only brings out the fact that individual turbine sizes are now available for zone power application, and his closing paragraph, while summating important conditions to be satisfied, points to his belief that real results can be accomplished by cooperating in the art of power production—this to my mind is the crux of the situation, for if plant *A* is inter-connected with plant *B*, then the customers of district *A* and those of district *B* both can enjoy the fruits of economical power production, as upon those joint districts could be impressed the voltage from selected machines of high efficiency synchronized upon a common transmission bus.

In comparing the economy of present power production throughout the Boston-Washington zone, with the proposed super-power system, I have stated elsewhere that the former will average at least, if not more than, 40 lb. of steam per kw-hour, and that the average consumption per kw-hour for the super-power line will not be greater than 15 lb. In this connection it is most interesting to note Mr. Johnson's figures of ten, or even less than ten pounds of steam per kw-hour.

As Mr. Johnson has pointed out, "Constant output at as nearly as possible full normal capacity is the first requisite to high efficiency or its equivalent, low cost of production." This is but another way of saying that there can be selected from the inter-connected plants of those now operating and those to be built, the high efficiency units, their size and location related to required distribution, to supply the base load, with the governors of each machine set to contribute its power at highest efficiency.

It is indeed encouraging to find no qualifications in Mr. Johnson's viewpoint regarding the super-power system, but rather a reference to the specific nature of the apparatus necessary to produce satisfactory results, and especially his reference to the adaptability of the multi-cylinder type. It is quite clear that Mr. Johnson's shop specifications are ready and this department of the super-power system only awaits orders to construct. Mr. Emmet and Mr. Johnson have given us the assurances regarding the steam element in the super-power generator. What do Mr. Reist and Mr. Newbury say regarding the other half of the turbo-generators? Mr. Reist says: "So many generators of from 30,000 to 50,000 kv-a. are at present in operation, giving satisfactory results, that there need be no hesitancy in considering generators such as those now used or larger."

Mr. Newbury says: "The generating element in the proposed Boston-Washington power supply system does not involve anything new or untried. The individual power stations need not, and probably would not, be any larger than stations now in operation, or under construction: Certainly any probable station involved in carrying out this super-power development could be designed with steam and electric generating units of size now available."

Mr. Reist's remarks regarding the standardization of potential, methods of insulation and the closed cycle of ventilation are indeed illuminating and all point to that reliability of construction so necessary to continuity of service. It is surely a step in the right direction, and a mark of determination to save thermal losses when, as Mr. Reist points out, the generator itself is made to function as a feed water heater. It may be said indeed that this will be a clean and efficient way to accomplish generator ventilation.

Mr. Reist has opened up an interesting suggestion regarding the consideration of fifty cycles as a standard for world's frequency. Personally, I cannot offer a friendly port to this thought. I believe our generating and transformer investment in the two generally accepted standards of frequency *viz.* 25 and 60 cycles is of an order too large to change now. Certainly, generating equipment of 40 and 62½ cycles should be discouraged. In Mr. Thomas' presentation of the transmission and distribution problem for the super-power zone much valuable suggestion is offered to confirm the standard for prime generating power at 60 cycles.

I think Mr. Newbury has pointed out a fact, not to be denied, in saying that the "super-power scheme will have to be developed by building up local central stations. Its growth must be outward from these centers; but I believe he would agree in the importance of inter-connection of plants through high-voltage transmissions to secure not only diversity factor of load, but *economic* generation and transfer of power from one district to another. The operator who has tried to secure for his company the maximum number of kw-hours per annum from the minimum number of tons of coal burned, has indeed, many times been burdened with the thought of the low efficiency of some of the turbines in his plant that he has had to run on base load when a neighboring plant has had a machine lying idle whose efficiency was the equal of his best machine. Diversity factor though important pales in value when compared to this. That is one of the operating conditions I infer Mr. Emmet had in mind when he made reference to cooperation. I can easily conceive of a tie line between two plants without a single kilowatt of additional capacity paying a handsome return on the investment necessary.

Mr. Potter's able contribution on the traction side of the problem leaves but a small amount of cement to bind it to this symposium. He has furnished the cement along with his paper. In short, he tells us that every form of railroad service, passenger, freight or switching can be performed and better performed, by the electric locomotive. The record of electric motive power now in service doing terminal, level and mountain service, and the mileage electrified, bespeaks

Submarine Detection in an Alternating Magnetic Field

BY J. B. WHITEHEAD
Professor of Electrical Engineering, Johns Hopkins University
AND
L. O. GRONDAHL
Associate Professor of Physics, Carnegie Institute of Technology

The paper describes a series of tests of the disturbance caused in a uniform alternating magnetic field by an incoming magnetic mass looking to the development of a device for the detection of enemy submarines.

Detection tests in the laboratory with submarine models 10 ft. long are in agreement with underlying theory and may be used as a basis for the design of larger equipment.

Detection tests on steel hulls from shore equipment and from equipment installed on a wooden submarine chaser 110 ft. long are in good agreement with results predicted from a formula developed in the laboratory tests.

By sufficient increases in the size of the equipment it is possible, in quiet water, to detect a steel vessel 200 ft. long at a distance of 500 ft. The weight of equipment required would be about 8000 lb.

Distances of detection in the neighborhood of 200 ft. were obtained in quiet water with equipment weighing 4500 lb. installed on a wooden submarine chaser 110 ft. long. The reliability of the system of detection is immediately impaired by motion of the vessel, due to her engines, heavy sea, and changes of course, or speed. The results mentioned involve the use of amplifier tubes for enlarging the signal. Without the amplifier the distances of detection are very short, even when a large magnet or large detecting coil and an extremely sensitive detecting instrument are used.

With amplifier, detecting coil and detecting instrument higher sensitivities may be reached than can be used in the detection tests. Disturbances in the detecting system fix the limit for increasing sensitivity. These disturbances are amplified and appear in the detecting instrument as larger than the signal sought.

Introduction

THE illegal and unforeseen methods of submarine warfare adopted by the Germans created an urgent demand for devices for detecting the hidden submarine. Practically no attention had hitherto been given to the development of such devices. So serious was the need that instructions were issued to government technical boards, requests to the national engineering societies, and a general invitation to the public to study the problem and make suggestions. As a result, hundreds of ideas, suggestions and plans were received through the several technical boards. Many of them were obviously worthless, and few, if any, from the nature of the problem gave promise of conspicuous success. A number of the more promising suggestions were developed experimentally and as based on the underlying physical principles they may be divided into two broad groups.

In the first group are the various methods of detecting sounds emitted by the submarine. These methods are more particularly adapted to the detection of the submarine at great distances. Devices of this character were brought to a high stage of development and extensive experiments were made with them. For obvious reasons data as to their performance is difficult to obtain,* but there is a general understanding that under favorable conditions the sound of the propeller or other machinery of a distant vessel can be detected at distances of several miles. One obvious limitation of these methods is that the enemy vessel may also be equipped with the same device and so can hear the approach of the searching vessel. Under these circumstances the submarine may come to a standstill or reduce its speed and noise to such an extent as to prevent the further estimate of its location by the searching vessel. A further disadvantage is the fact that the machinery of the listening vessel must be stopped during observations.

The second group embraces those methods which depend on the magnetic and electrical properties of the hull of the submarine. Most of these methods make use of the earth's magnetic field. The presence of the submarine disturbs the earth's field and effort is made to detect the distortion so caused. Other magnetic methods involve the establishment of an independent magnetic field by the searching vessel itself and the presence of the submarine is detected by the distortion of this field. The experiments which are to be described in this paper fall within this latter class.

The magnetic methods, by reason of the underlying physical laws, are adapted only to relatively short distances of detection. The strength of the magnetic field, due to a magnet, varies inversely as the cube of the distance from the magnet, and consequently the signal on a searching vessel received from a magnetized submarine falls off rapidly with increasing distance. On the other hand, the limitation of the listening device mentioned in the foregoing paragraph means that these methods cannot be used at short distances. Detecting devices therefore, having even a relatively short range, promised to be of value.

The experiments described in this paper aimed to develop a short-range magnetic detector. They were begun shortly after the entrance of the United States into the war, under the direction and support of the

*L'Illustration, February 8, 1919.

NOTE. The work described in this paper was carried out first at the Johns Hopkins University and then at the United States Naval Academy, under the direction of the Naval Consulting Board. The results of all the work have been communicated in a confidential report to the special Problems Committee on the Board, and permission has now been given for the publication of any portions which appear of purely scientific interest.

The body of the paper is generally descriptive in character and more detailed descriptions of the difficulties encountered and the methods of experimental attack are given in a series of appendices.

Naval Consulting Board. The fundamental idea on which the experiments were based was first suggested by Major (now Lieutenant-Colonel) Ralph D. Mershon, who was in general charge of the experimental work conducted by the Special Problems Committee of the Board. The first of the experiments were conducted in the Laboratory of Electrical Engineering of the Johns Hopkins University, and afterwards the work was continued on vessels afloat at the Engineering Experiment Station, U. S. Naval Academy, Annapolis, Md.

General Description

Of the various devices suggested for the detection of a submerged submarine making no noise, probably the simplest and most obvious are those making use of the magnetic and electrical properties of the hull. If the submarine comes into a magnetic field it becomes magnetized and consequently its presence may be detected by suitable measuring instruments. For example, if a detecting vessel carries a magnet or is itself magnetized, a submarine in its neighborhood will become magnetized. If the magnet be excited by alternating current, the magnetic field and the magnetization of the submarine will be alternating. A suitable detecting instrument on the detecting or searching vessel will then indicate the presence of the submarine, particularly if the instrument is compensated against the influence of the field of the magnet itself.

The principle of the device now described will be best understood from the following description by Lieutenant-Colonel Mershon:

> The most promising method so far proposed for the detection of submarines by an alternating magnetic field is this: An alternating magnetic field is set up by an alternating-current magnet having an open magnetic circuit;—a straight bar magnet so designed as to give as far reaching and as strong a field as is practicable. In the field of this magnet, and as far away from it as is practicable, is located a detecting coil. This coil may be located with its plane parallel to the lines of force set up by the magnet, in which case it will theoretically have no voltage induced in it by the magnet itself; or, it may be located with its plane not parallel to the lines of force, in which case the voltage induced in it by the alternating field set up by the magnet must be balanced out by another electromotive force exactly opposed in phase and magnitude to the voltage induced in the detecting coil. If the conditions aimed at are realized, there will, in either of these cases, be no resultant electromotive force in the circuit including the detecting coil, and no indication thereof in such means as may be employed for detecting an alternating e.m.f. in this circuit. If, now, a submarine comes into the field set up by the magnet, the submarine will disturb the field existing around the detecting coil, with the result that there will be an alternating voltage produced in the detecting coil circuit which will indicate the presence of the submarine, and may also indicate its location.

The current due to the electromotive force induced by the submarine in the detecting coil may be measured in a number of ways and in particular it may be rectified by a commutator mounted on the shaft of the generator supplying the magnet, and read on a continuous-current measuring instrument. The use of an alternating magnetic field and a commutator has a number of advantages. The system is independent of motion in the earth's magnetic field. It has a selective property, since the commutator will "chop up" disturbances of lower frequency. Under certain circumstances disturbances of higher frequency may be filtered out by suitable combinations of inductance and capacity. The signal e.m.f. is received in a detecting coil and an increase in the size of this coil affords one way of increasing the magnitude of the signal received from the submarine and therefore increasing the distance of detection. The e. m. f. in the detecting coil due to the magnet itself may be balanced out in a number of simple ways. Finally by means of the commutator a continuous-current detecting instrument may be used.

As is well understood, the strength of the magnetic field due to a magnet falls off very rapidly with increasing distance from the magnet. For distances large in comparison with the length of the magnet, the strength of field is inversely as the cube of the distance from the magnet; that is to say, the strength of magnetic field at the submarine will be inversely as the cube of its distance from the magnet. This is a serious enough limitation, but is only half the story in submarine detection. For detection of the presence of the submarine it is necessary that the magnetized submarine itself set up a field at the detecting coil sufficient to generate in that coil an electromotive force which may be detected by the usual available types of detecting instrument. This return signal from the submarine varies also inversely as the cube of the distance. Consequently, the signal in our detecting coil will vary roughly inversely as the sixth power of the distance to the submarine.

The relations outlined in the foregoing paragraph are at first sight most discouraging and indeed apparently insuperable. There are, however, several ways in which much of the handicap of the inverse sixth power may be offset. In the first place, the dimensions of the modern submarine are so great that its magnetic moment, even in a field of low intensity, may still be of appreciable magnitude. The signal received in the detecting coil may be increased by increasing the volume of the coil. The strength of the magnetic field at the submarine may obviously be increased by increasing the size of the magnet. And finally, we have now available in the three-electrode amplifier or pliotron tubes a means for stepping up a minute electric signal several hundreds of thousands of times. With the use of such tubes, it is theoretically possible to offset in large measure the limitation imposed by the inverse sixth power of the distance and to reach distances of detection which would be extremely important in submarine warfare.

It is obviously possible to compute approximately the moment of a magnet necessary for setting up a given field strength at a given distance, the size of de-

tecting coil for receiving a definite signal in a field of given strength, and the degree of amplification which may be given to such a signal by the use of amplifier tubes. It is not possible to predict however the magnetic moment of the hull of a submarine in a field of given intensity, nor to say what limits of amplification may be applied under the conditions of our problem. Experiment is therefore necessary before any safe conclusions can be drawn either as to the size of the equipment or as to its practicability.

As regards the magnetization of a submarine, if it were placed in a uniform magnetic field in the direction of its axis, it would still be impossible, owing to its unsymmetrical shape, the riveting of its plates and the uncertainty as to its interior structure, to make even an approximate estimate of its magnetic moment. Aside from this, the shell of the submarine when placed in an alternating magnetic field will have set up in it circulating or secondary currents. The magnetic field due to these secondary circuits will, in general, differ both in magnitude and in phase from that due to the magnetization of the hull. The relative importance and net magnetic moment due to these influences are obviously matters for experimental determination.

There is also another important and indeterminate factor. The detecting coil, in view of its position on the detecting vessel, will be relatively close to the magnet, consequently it will have induced in it a large electromotive force due to the magnet. This electromotive force must be balanced out and the coil be retained, as far as possible, in a neutral electric condition, for this is the condition of maximum sensitivity toward the signal from the submarine. This consideration demands as nearly as possible a rigid relation in space between the magnet and coil. On shipboard it is a question as to just how definitely it is possible to retain such a fixed relation. In considering this question it appeared certain that vibration and motion of a boat due to its driving machinery and to its rolling in a heavy sea would, to a greater or less extent, upset this desirable rigid relation between magnet and coil. The exact amount of this upset and whether it would be great enough to seriously impair the method were questions which could only be answered by actual tests on shipboard.

Experiments at Johns Hopkins University

Since the underlying relations of the method are reasonably clear, the uncertain factors being the values of the constants involved, the problem was first attacked by laboratory tests aimed to determine whether distances of detection which would be actually useful could be reached. Using the constants obtained in these laboratory tests, distances of detection for larger equipment were computed. Tests of this character were carried out in the Laboratory of Electrical Engineering of The Johns Hopkins University. These tests will be described first and the computations given upon which the design of the larger equipment was based.

The tests comprised studies of the types of magnet and detecting coils, of the method of balancing the electromotive force in the detecting coil due to the magnet, various types of commutator and detecting instrument, the use of amplifying tubes, the choice of alternating frequency, types of speed control and tests of the formulas by which the results to be expected in actual service were computed. Each of these investigations contributed to the design of the final equipment. The successive steps in each of these studies are of interest and value but have no necessary place in a direct statement of the experiments and conclusions of the investigation. Therefore only brief mention of them will be made as occasion requires.

The general arrangement of the essential elements is shown in Fig. 1 and the electric connections of the detecting circuit in Fig. 2. Referring to Fig. 1, S is a model submarine, M is the magnet excited by alternating current, C is a detecting coil and C' a balancing coil. Two arrangements of the relative positions of S, C and M are shown, these being the two most important from the standpoint of detection at a distance.

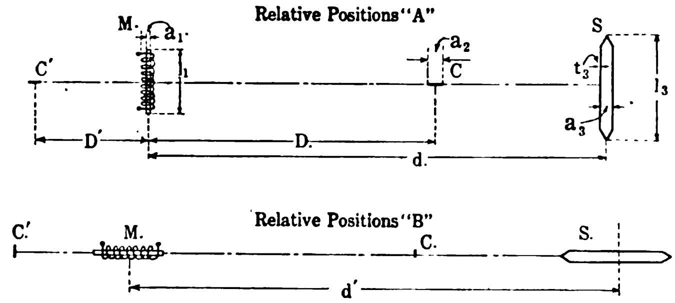

Fig. 1—Laboratory Tests

Submarine Model S. The model was made of galvanized iron 0.025 in. thick. It was cylindrical in shape with conical ends, the altitude of these ends being 1 ft. The length overall was 10 ft. and the diameter 1 ft. The length, diameter and thickness of wall are in approximately the same ratios as those pertaining to a late type of submarine of length 200 ft. There were five sections in the model, including the ends, the joints being telescoped without soldering.

The submarine model was mounted on a small wooden truck rolling on a graduated wooden track, thus permitting approach of the submarine to the detecting coil and magnet, and measurement of the distance at which a standard signal of detection was received in the detecting instrument G.

Submarine models of other dimensions and characteristics were also used, and an extensive study was made of the influence of variation of dimensions of the model on the signal received.

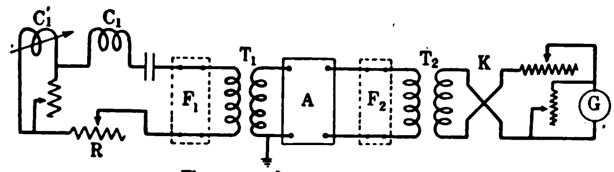
The Magnet M_1. The magnet M_1 had a laminated iron core 6 ft. long and 8.81 sq. in. (66.8 sq. cm.) cross

section. The core was bolted together and wedged in a piece of 4-in. internal diameter fiber conduit, over the outside of which the exciting winding was placed.

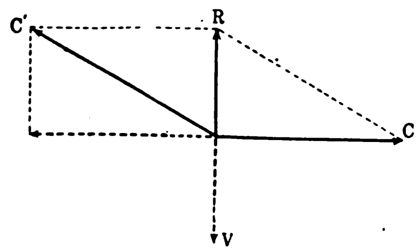
The exciting winding consisted of 28 coils, each having 52 turns and all connected in parallel. The coils toward the poles had a progressively increasing cross section of copper. The total length of the winding was 69 in., thus leaving a polar extension of the core of 1.5 in. at each end. The object of this method of winding was to maintain the flux in the core uniform over approximately its full length, thus increasing the effective length of the magnet.

At 30 cycles the magnet absorbed 200 amperes at 22.6 volts, *i.e.*, 4.52 kv-a. The power factor was 0.2. This excitation was used in the tests described below.

The Detecting and Balancing Coils. A number of coils of different sizes and characteristics were used as the detecting coil and as the balancing coil. The two coils used most commonly were of the same dimensions, having an outside diameter of 9.5 in., inside



– Elements of Detecting Circuit –



Emfs. of Detecting Circuit

FIG. 2

diameter of 5.75 in., the detecting coil, C_1 having 2000 turns of No. 22 B. & S. wire, and the balancing coil C_1' 306 turns of No. 14 B. & S. wire. The resistance of the detecting coil was 70 ohms and its inductance 1 henry.

As indicated in Fig. 2, the detecting and balancing coils are connected in series. The electromotive forces in the two coils are in opposition and the purpose of the balancing coil C_1' is to counterbalance exactly the electromotive force induced in C_1 by the field of the magnet. In this condition there is no current in the detecting instrument and an incoming submarine upsets the balance, causing a current in the detecting circuit and detecting instrument. Obviously, if C_1' is placed relatively near the magnet, it need have fewer turns relative to C_1. In this way the countersignal in C_1' due to the magnetized submarine is reduced to a negligible value.

The Generator. The generator was a 50-kv-a., 240-volt, single-phase, 60-cycle machine, directly connected to a 240-volt, d-c. compound-wound motor. The preliminary experiments having shown that the method was most sensitive at frequencies near 30 cycles, it was necessary to drive this machine at half speed. This was done by reducing the voltage on the motor armature running the fields of both motor and generator at approximately full excitation.

Mounted on one end of the shaft of the generator was the commutator for rectifying the signal delivered to the direct-current detecting instrument G, Fig. 2. This commutator was carefully constructed. It had six segments corresponding to the number of poles of the generator and the segments were separated by very narrow mica insulation which with narrow brushes permitted very close adjustment of the brushes with references to the zero of the alternating current. Worm and gear fitting for the brush holder aided in this accurate adjustment.

The Detecting Circuit. The simplest arrangement of the detecting circuit consists of the detecting and balancing coils, and the detecting instrument with its commutator all connected in series. With this arrangement it is possible to obtain a good balance of the system, but the distance of detection is quite small. With a detecting instrument of a given sensitivity, the distance of submarine detection can be increased only by increasing the sizes of the magnet and detecting coil. The tests with these simple elements of equipment and the computation in connection with them, indicate that an increase of the distance of detection by this means soon involves prohibitive sizes and weights for the magnet and coil.

It is important therefore that the sensitivity of the detecting instrument be increased so that signals corresponding to greater distances of the submarine may be detected. However, great sensitivity in the instrument itself usually means delicate construction and a thread suspension and these are not suitable for use on shipboard.

Fortunately, it is now possible in effect to increase the sensitivity of a rugged type of instrument to figures which are quite beyond those pertaining to the most delicate laboratory instruments. This is accomplished by the use of amplifier or pliotron tubes, now in common use in telephony, telegraphy and radio transmission. The properties of these tubes are now well understood and they need not be described here. They serve in effect a relays, in which extremely small amounts of energy in the form of electric signals may be used for liberating correspondingly greater signals from a local circuit, and transmitting them to the detecting instrument. The combination of amplifier and detecting instrument therefore results in a sensitivity far beyond that of the instrument alone, so that a rugged and substantial type of instrument may be used—a very important feature for service on shipboard.

The essential elements of the detecting circuit are shown in Fig. 2. C' is the balancing coil with an ad-

justable resistance across its terminals. It is connected in series with the detecting coil C_1 with a condenser C, with a frequency filter F_1, a transformer T_1 and a control resistance R. The transformer is for the purpose of adapting the characteristics of the detecting circuit to those of the amplifier A. For a given disturbance in the detecting circuit the maximum signal in the transformer will be obtained when the inductive reactance of the detecting circuit is neutralized by capacity C and the resistances of the detecting coil and transformer are equal. The total voltage generated is then divided equally between the detecting circuit and the circuit to which it is connected. The same considerations apply to the output circuit of the amplifier in its relation to the detecting instrument G. The transformers T_1 and T_2 are for the purpose of introducing receiving and delivery circuits of impedance approximately equal to those pertaining to the detecting circuit and detecting instrument respectively. The filters F_1 and F_2 consist of combinations of resistance, inductance and capacity and are for the purpose of cutting out disturbing frequencies above 30 cycles. The amplifier was arranged so that any number of stages from 1 to 5 might be used.

The Detecting Instrument. The most satisfactory type of instrument, as developed by experience, has been found to be a direct-reading, needle-type, double-pivot D'Arsonval galvanometer with zero in the center of its scale. The instrument most used in the present experiments was of this type and had a sensitivity of 10^{-6} amperes per millimeter of scale. It had a scale of 25 millimeters on each side of the zero position. The resistance of the instrument was 100 ohms and the critical dampening resistance 90 ohms.

In efforts to introduce the greatest sensitivity by means of the instrument, other types were also used, as for example, the Einthoven string galvanometer, a high sensitivity electro-dynamometer and sensitive suspension types of D'Arsonval galvanometer. These instruments are in general unsatisfactory by reason of their delicate construction. Not only does this construction render them unsuitable for use on shipboard but the circuit in which they are connected contains the coils C_1 and C_1', in each of which a very large electromotive force exists. During the process of balancing, there are frequently liberated in the detecting circuit electromotive forces of magnitude far beyond that of the signal to be detected. With an instrument of delicate suspension extreme caution is necessary to avoid disastrous consequences. The instrument mentioned above combined ruggedness and sensitivity to an unusual degree and withstood many hard knocks without damage.

The Experiments. The principal problem in the taking of observations is to secure and to maintain an exact balance of the electromotive forces set up in the coils C_1 and C_1'.

It was found by separate experiment that the phase of the signal received from the submarine is practically coincident with that of the main magnetic field due to the magnet. The brushes of the commutator therefore must be set so as to correspond with the electromotive force induced in C_1 by the main magnetic field. This is readily accomplished by cutting out C_1' and inserting enough resistance in the detecting circuit to insure that the resulting current is in phase with the electromotive force and at the same time that the current in the detecting instrument is within its capacity. This being done, the brushes may be adjusted for zero deflection of the measuring instrument, when the signal will be cut up into an equal number of positive and negative parts. A shift of the brushes by 90 electrical degrees will now bring their setting to the point corresponding to the maximum signal due to C_1 alone.

The problem of the balance is to introduce from C' an electromotive force exactly equal in magnitude and opposite in phase to that in C_1. Unfortunately the phase in the magnetic field of the neighborhood of the magnet differs appreciably from point to point. It is relatively easy to find a position in which the value of the electromotive force in C_1' is equal in magnitude to that of C_1, but quite difficult to find a point at which their phases are exactly the same. This was the most difficult of all the problems arising in the experiments. An extensive series of investigations was made on the method of balancing and it was found that the simplest and most accurate method was to adjust the phase of the electromotive force at the terminals of the balancing coil C_1' by varying its shunt resistance. (See Fig. 2). The value of the balancing electromotive force could then be varied by rotating the balancing coil about an axis normal to the direction of the field. The technique of the method is given in Appendix E.

The degree to which the equality of both magnitude and phase of the two opposing electromotive forces is obtained is measured by the constancy of the zero position of the pointer of the galvanometer. If they are not in phase slight changes of frequency will cause sharp upsets of the balance. Naturally it is more and more difficult to obtain a balance the greater and greater the degree of amplification that is used. In fact the limit of sensitivity of the whole apparatus is found by increasing the number of stages of amplification. With increasing amplification the wandering or jerks of the needle about the zero position become greater and greater and more and more irregular until finally they will mask the deflection due to the incoming signal. These disturbances of the balance are largely associated with variations of the speed of the generator. The greater the refinement in the control of the speed, the greater the degree of amplification which may be used, and consequently, the greater the sensitivity of the apparatus and the greater the distance of detection. A further description of the experiments on the balance in the detecting circuit is given in Appendix E.

The general method of taking observations was to

obtain a satisfactory balance, and then bring the submarine model toward the detecting coil until a standard signal was received, the distance from the magnet being observed. Throughout the experiments the distance of detection was measured between the centers of the magnet and the submarine. The readings were repeated sufficiently often to be certain of the distance of detection. The standard signal in these laboratory experiments was 15 millimeters of scale with a zero disturbance not greater than plus or minus five divisions. In general a ratio of signal to zero disturbance, 3 to 1, has been adopted throughout the experiments.

Experimental Results. Numerous experiments with both arrangements of Fig. 1 and with and without the use of an amplifier were conducted. Quite satisfactory observations were obtained without the amplifier and with the amplifier using up to three stages. Beyond this point, even under the most careful control of all conditions, obscure disturbances were magnified by the amplifier to a point where they were comparable with the ordinary signal due to the submarine model and therefore masked them. With prolonged investigation of the source of these disturbances and under carefully chosen conditions it was found possible to work with four stages of amplification. The conditions are quite unstable, however, and difficult to obtain; the results were therefore considered to be unsuitable as a basis for prediction of future results.

Without the use of amplifier the distances of detection of the model S were relatively small. Detection was definite at 15 ft. from center of magnet to center of submarine model, but 10 ft. with a galvanometer deflection of 1 cm. was taken as the conservative maximum distance.

With three stages of amplification distances in the neighborhood of 50 ft. were obtained, and for the standard signal on the galvanometer the distance, by a number of observations, was 44 ft.

Possible Distance of Detection as Estimated from Laboratory Tests

The results of the laboratory tests were made the basis of a computation of the distances of detection to be expected with enlarged equipment and the full-sized submarine.

The magnetic field strength or intensity due to a bar magnet at a point on its axis is

$$f = \frac{2\,M}{d^3} \tag{1}$$

and at a point on a line normal to the axis and passing through the center of the magnet

$$f' = M/d^3 \tag{2}$$

where M is the moment of the magnet and d is the distance of the point from the center of the magnet; d is assumed to be large compared with the length of the magnet.

Let l_1 and a_1 be the length and diameter of the core of the magnet M Fig. 1; l_2, a_2, t_2 and V_2 the length, mean diameter, radial thickness and volume, respectively, of the detecting coil C_1; and l_3, a_3 and t_3 the length, diameter and thickness of shell, respectively, of the submarine.

Let the magnetic field intensity at S due to M be f_1, then in either arrangement of Fig. 1, if the magnetic flux density in the core of M has always the same value

$$f_1 = K_1 \frac{l_1\,a_1^2}{d^3} \tag{3}$$

also the field intensity at C_1 due to S will be

$$f_2 = K_2\,f_1 \frac{l_3\,a_3\,t_3}{(d - D)^3} \tag{4}$$

This assumes that the whole length of the submarine is subjected to the same magnetic intensity and that the resulting flux is proportional to the cross section of its skin, that is, to the product of its mean diameter and the thickness of its plates. These assumptions are obviously open to question, but they are approximately correct when d is large compared with l_1 and l_3. Independent experimental studies of this relation were made particularly for values of d comparable with the length of the submarine. See Appendix D.

The electromotive force induced in the detecting coil will be proportional to f_2 and will also depend upon the dimensions and number of turns in the coil. The signal on a given detecting instrument will be a maximum when the resistance of the detecting coil is equal to that of the instrument and when the reactance of the coil is completely neutralized. We will assume then that the resistance R of any larger detecting coil will have the same value as that of the coil used in the above experiments. This value was approximately equal to the resistance of the detecting instrument used. We have then if l is the axial length, t the radial depth, a the diameter, and n the number of turns in the coil C_1

$$R \propto \frac{\pi\,a\,n}{\frac{l\,t}{n}} = \text{const.} \tag{5}$$

$$\therefore n = K \sqrt{\frac{l\,t}{a}} \tag{6}$$

The e. m. f. in the detecting coil e is

$$e = k_1\,a^2\,n \tag{7}$$

$$= k_2\,a^2 \sqrt{\frac{l\,t}{a}} \tag{8}$$

$$= K_3\,a\,V_2^{1/2} \tag{9}$$

Thus the e. m. f. or signal in the detecting coil due to the magnetic field f_2 set up by the submarine will be

$$S = K_1\,K_2\,K_3 \frac{l_1\,a_1^2\,a_2\,V_2^{1/2}\,l_3\,a_3\,t_3}{d^3\,(d - D)^3} \tag{10}$$

and if an arbitrary constant signal in the detecting instrument be selected, the distance of detection for any magnet, coil and submarine is

$$d = D/2 + \sqrt{K\,(l_1\,a_1^2\,a_2\,V_2^{1/2}\,l_3\,a_3\,t_3)^{1/3} + D^2/4} \quad \textbf{(11)}$$

By substituting in the above expression the distances of detection, the dimensions of the magnet, detecting coil and submarine model, used in the experiments described above, the value of K may be found and d may then be computed for any size of magnet, coil and submarine by substituting the proper values for l_1, a_1, a_2, etc. Obviously in this method of computing d it is assumed that the magnetic flux density in the core of the large magnet is the same as that in the core of the small magnet M_1 used in the experiments.

In the above development, no account has been taken of the signal in the balancing coil C_1'. In all of the experiments the number of turns in this coil has been small compared with the number in the detecting coil and its area has also been relatively small. In order to obtain the value of the electromotive force necessary to balance that in the detecting coil, it has only been necessary to place the balancing coil nearer to the magnet. Simple computation shows that in all the experiments the countersignal in the balancing coil C_1' due to the submarine was in all cases negligible compared with the main signal in C_1.

Making the substitutions mentioned above for the case when the amplifier is not used, and using the foot as the unit of length, a value of K, 31.3, is obtained which enables us to predict the possible distance of detection with the simplest elements of apparatus; that is, no amplifier being used. A submarine of recent type may be assumed as having a length of 200 ft., average diameter of 20 ft. and a thickness of skin 0.03125 ft. Substitution in formula (**11**) of these figures shows that in order to obtain even moderate distances of detection quite large sizes of both magnet and detecting coil would be necessary. For example, with a magnet 25 ft. long and core 1 ft. in diameter and a detecting coil 10 ft. in diameter and 9 sq. in. cross section, and a distance of 50 ft. between the magnet and detecting coil the distance of detection is found to be 185 ft. which is too short to be of value. Bearing in mind the equipment necessary to excite so large a magnet and the space requirements for the magnet and coil, it will be seen that the device promises little value unless the magnitude of the signal can be greatly increased, thus permitting a smaller size and mass of equipment and at the same time a greater distance of detection.

The outlook is considerably improved when we consider the tests in which the amplifier was used. When the distances obtained in these tests are substituted in formula (**11**), the value of the constant K is increased to 7730 approximately 25 times. Using this value, together with the constants of a submarine given above it was found that with a magnet 16 ft. long, 9 ft. in diameter and a detecting coil 7 ft. in diameter and 9 sq. in. radial cross section, distances of detection of from 450 to 500 ft. are indicated. These results were considered to be sufficiently promising to warrant the construction of enlarged equipment and further tests on actual vessels.

Experiments At Annapolis

Particularly favorable conditions were found at the Engineering Experiment Station, Annapolis, for conducting some intermediate tests on actual steel hulls of full size, without the necessity of diverting from other purposes a vessel on which the detecting apparatus would be assembled. In view of the uncertainty as to what bearing the character of the hull of a steel vessel would have on the results, it was deemed advisable to undertake experiments with enlarged magnet and coils and the use of steel hulls approximating those of the modern submarine, before going to the more elaborate and expensive equipment necessary on shipboard.

The detecting coil, magnet, motor generator, etc., were assembled on the end of a pier reaching into deep water and well removed from possible disturbing influences. The Experiment Station offered complete facilities for the construction and assembly of much of the necessary equipment. Electric power was also available in ample quantity.

In order that all factors entering might be made as large as consistent with their convenient usage, and so increase the maximum distance of detection, it was determined to build a magnet with the largest possible moment with an excitation of 26 kv-a., the limiting capacity of the available motor-generator set. This magnet which we will call M_2 had an effective length of 16 ft. and an overall diameter of approximately one foot. Its weight mounted on its base was 4000 lb.

The detecting coil C_2 constructed for these experiments had a mean diameter of 7 ft. and a winding cross section 3 in. by 3 in. It contained 1307 turns and had a resistance of 60.7 ohms and an inductance of 8.22 henrys. Its total weight mounted in its frame was 1500 lb.

The balancing coil C_2' was 3 ft. in diameter with a winding cross section 2 in. by 2 in. It had 530 turns and 9.86-ohms resistance. This coil was adjustable about a diameter arranged as a vertical axis. Its exact position could be accurately controlled and set by means of a worm screw and gear. Its weight in its mounting was 525 lb.

The motor-generator set with its speed control equipment, used in the Johns Hopkins University tests, was also used at Annapolis. In all other particulars as regards amplifier and other auxiliaries the apparatus was assembled and operated in the same manner as pertained to the Baltimore experiments. In these experiments which can only be mentioned here, many new conditions attendant upon the enlarged equipment were encountered. In particular much new information as to the detecting circuit, the importance of speed

control, and the elimination of disturbances was obtained.

The vessels on which the detection tests were made were the ocean tug "Standish" and the converted yacht "Wasp". Their respective dimensions are as follows:

Standish: Length overall, ...150 ft.
Beam, ... 27 ft.
Depth, ... 11 ft. (from deck to keel)
Skin, wrought iron ½ in. thick,
Wooden deck on steel frames 18 ft. apart.

Wasp: Length overall, ...203 ft. 9½ in.
Beam, ... 23 ft.
Depth, ... 18 ft. (from rail top to keel)
Skin, steel ⅝ in. thick with additional armour belt amidships 55 ft. long, 6 ft. wide and 1 in. thick.

The pier at the Experiment Station projected toward deep water and had a dock or basin alongside. The detecting coil was set up on the extreme corner of the pier and the magnet placed in various relative positions. The balancing coil was shifted to various convenient positions in relation to the magnet, and close to the balancing coil a small observing platform, protected from the weather, carried the detecting instrument and balancing equipment. The amplifier and the motor generator for exciting the magnet were located nearby in the Station, permitting ready access for commutator setting, speed control, inspection of amplifier. etc.

In taking observations a satisfactory balance of the detecting instrument was first obtained by the method described in Appendix E. A wig-wag signal was then sent to the vessel to approach on a prearranged course. Her position at all times was observed by a simple system of triangulation. When the signal was received on the detecting instrument the observer near the balancing coil signalled by means of a bell and the position of the vessel was thus noted at the corresponding moment. A corresponding signal was generally taken as the vessel passed out of range.

A large number of detection observations were taken with both arrangements indicated by Fig. 1 and with the vessel approaching on different courses. The maximum distances of detection reached were in the neighborhood of 450 ft. and were therefore in general accord with those predicted from the laboratory tests in the manner indicated. Fig. 3 shows graphically the results of one series of tests.

Detection Tests Afloat

It is obvious that the distances of detection which have been mentioned are dependent strictly upon the degree of sensitivity which is used in the detecting circuit. Throughout the experiments it was always found that in the combination of amplifier and measuring instrument it was possible to obtain figures for sensitivity higher than it was possible to use by reason of the limitations of the exact balance between the detecting and balancing coils. One vital factor affecting the balance is a fixed relation between the magnet, detecting and balancing coils. If any one of the three moves, with reference to the others, the balance is correspondingly upset. It was realized, therefore, considering further tests on shipboard, that there was a large chance that the distances predicted might be seriously curtailed, if not entirely lost, by reason of the vibration due to the engines of the vessel and to the straining or distortion of the hull of the vessel due to the motion of the sea. There appeared also a possibility that these factors might have an influence on the delicate relations obtaining in the amplifier tubes and on the detecting instrument. However, the unusual steadiness of the submarine chaser, as regards her engines, seemed to offer exceptionally favorable

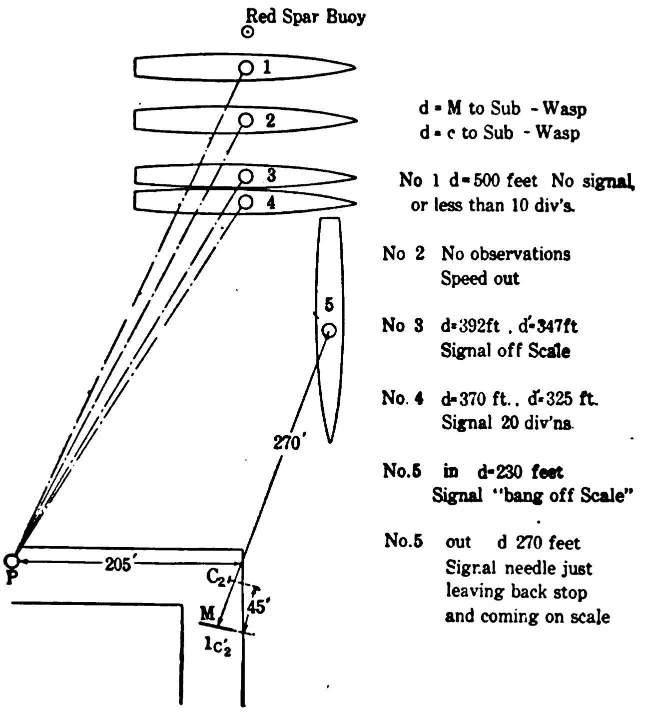


Fig. 3—Detection Tests—Yacht "Wasp"

3 stages and transformer.
10-ohm shunt. Excitation 93 amperes; 50 volts; 4.65 kv-a.
Distances Measured by triangulation from point *P*. Balance conditions good at constant speed; needle returned to center of scale after all signals.

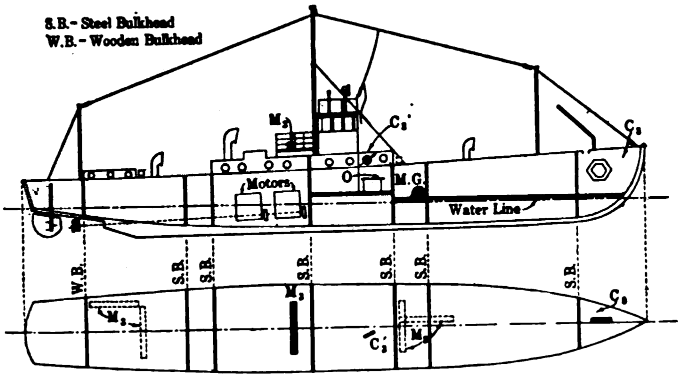
conditions in this respect. Moreover, a promising method of spring suspension for the amplifier and a robust detecting instrument which seemed to be independent of moderate motion also gave promise of partially avoiding the difficulties mentioned.

The submarine menace at this time was at its most serious stage. No reliable detection devices existed, and every possible chance for the development of such a device was being encouraged. Submarines are limited to about 200 ft. of submersion and it was felt that if half the distances obtained in the shore tests could be reached in reliable fashion the method might prove of value. In view of the good agreement between the computed and the observed distances in the foregoing experiments, it was therefore decided to

construct and install the equipment, described below, on Submarine Chaser No. 326, stationed at Annapolis and placed at the disposal of the Naval Consulting Board at the request of the Special Board of the New London Naval Experimental Station.

The total weight of the equipment used in the shore tests, 17,000 lb., was unnecessarily large, even for a magnet of the capacity of M_2. This was principally due to the fact that the motor generator was of higher rating than that of the magnet and no special effort had been made to limit the weight of several other portions of the equipment. Moreover, tests both in the laboratory and at the Engineering Experiment Station had shown that it was possible to obtain good results with considerably lower figures for the excitation of the magnet. This is in accord with theory, as the distance of detection varies approximately as the sixth root of the total flux emanating from one pole of the magnet. (See formula (**11**)).

The method requires the use of a wooden vessel. The number of such vessels available, of length greater



Scale—1 in. — 12 ft.

Fig. 4—Submarine Chaser, "S. C. 326"

than 100 or 150 ft., is very limited. The 110 ft. submarine chasers were seen to possess many features advantageous for testing this method. Not only have they wooden hulls, but they are driven by three gasoline engines of six cylinders each, and this feature results in extreme steadiness when under way. In addition it will be seen, from a description below, that the space on board was admirably adapted to the accommodation of the necessary equipment. A study was therefore made as to the maximum equipment which could be installed on one of the chasers, the magnet being limited to the capacity which could be furnished by a 3½-kw., 120-volt, d-c. gasoline-driven generator, installed on the chaser for pumping and other purposes. As based on tests on shore, it appeared that it should be possible, with this equipment, to reach distances of detection which would be useful though considerably less than those obtained with the larger equipment in the shore tests.

Submarine Chaser No. 326. The "326" (See Fig. 4) is 110 ft. long, 15-ft. beam midships and has an average depth from deck to keel of about 10 ft. She is of wooden construction throughout except that she has six water-tight steel bulkheads. Other metal masses are the engines, propeller shafts, rudder, ventilators, air and gasoline tanks, anchor, stanchions, deck posts, etc. Outline drawings of elevation and deck plan, shown in Fig. 4, indicate the construction of the vessel and the relative location of her equipment, the steel bulkheads, and the experimental apparatus.

The earlier experiments had shown that the proximity of masses of metal had no effect on the balance conditions as long as these masses were stationary. Several rough experiments were made in order to determine the influence of such masses and no striking influence was found. It was always possible to secure practically the same conditions of balance when the metal mass was present or absent.

It was recognized, however, that the steel bulkheads of S. C. No. 326 offered a condition which had not been considered in the earlier work. These bulkheads, stretching the full width of the ship, are longer than the magnet and no positions for the magnet can be found which are very far removed from some one of these bulkheads. The influence of the bulkheads therefore was an uncertain factor. Subsequently, a number of experiments were made to determine this influence and it was found that the phase of the magnetic field near the bulkheads was markedly affected by them, that the influence on the balance could be eliminated, and that the influence on the sensitivity, while appreciable, was not great.

The Motor Generator. The generator was a 5-kv-a. single-phase, 60-cycle machine, directly connected to a 220-volt, compound-wound, d-c. motor, operated at full excitation and half voltage, thus driving the set at one-half speed for 30 cycles. The power for the set was supplied by the 3½ kw. gasoline auxiliary set, already described, which was located in the engine room. The motor generator, together with all of its control equipment, was located in the magazine, as indicated at *M G*, Fig. 4.

On one end of the shaft was located the rectifying commutator of the detecting circuit. The other end was equipped with special control devices, including ball thrust bearings, for constant speed regulation, as described in Appendix B. There is no more important feature for a balance of high sensitivity in the detecting circuit than constancy of speed, and much time and effort were devoted to perfect the two speed control methods described in Appendix B.

The Magnet M_3. The core of the magnet was 9 ft. long and had a cross section of 7.7 sq. in. (49.5 sq. cm.). The core was placed inside a piece of 4-in. internal diameter fibre conduit, over the outside of which the exciting winding was placed. This winding consisted of six similar one layer coils of 104 turns each, No. 10 B. & S. cotton covered wire, all connected in multiple. The length of the core beyond the winding at each end was 15 in. The magnet was mounted in a suitable wooden frame and housing.

In Fig. 4 the magnet is shown as located on the bridge of the chaser just abaft the pilot house. Other positions in which observations were made are indicated in dotted line on the deck plan.

The Detecting and Balancing Coils C_3 an C_3'. Two features are desirable for the location of the detecting coil; one that it should be below decks, and the other that it should be as far as convenient from the magnet, the latter for its bearing on the conditions of balance. The location combining these two particulars to best advantage was found in the forward hold of the chaser. A serious drawback to this position was that entrance to the hold was limited to a manhole 18 in. in diameter in the deck. However as none of the hatches on the

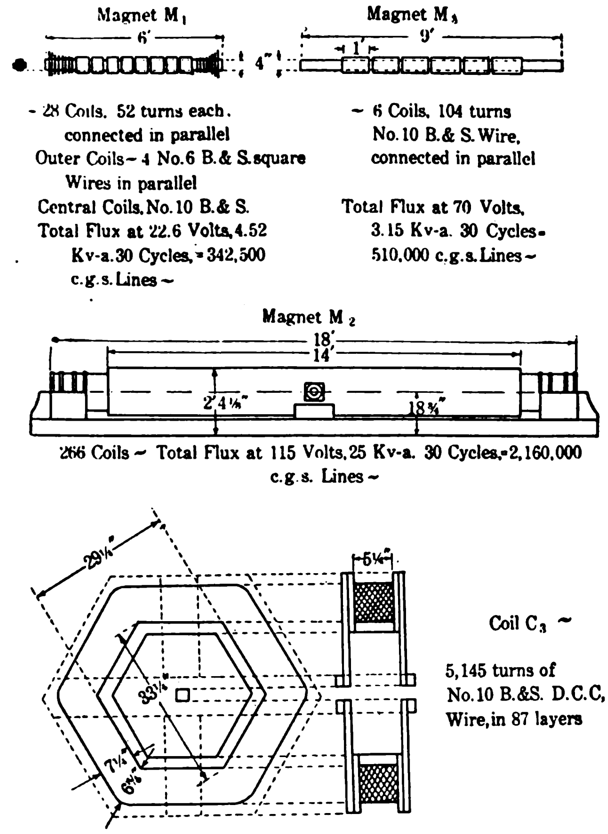


Fig. 5

vessel was large enough to accommodate a coil of the size required, it was realized that in any position below decks the coil would have to be wound in place.

The coil as finally wound was hexagonal in shape, this shape being adopted for convenience in construction and assembly of the wooden form on which the coil was wound and permanently supported. Its dimensions, shown in Fig. 5 were the largest possible in the available space, having in mind the importance that for the experiments it would be located with its plane athwartship, as well as at right angles to this position, and also that it should be kept a reasonable distance from the nearest steel bulkhead. In winding, the wooden form was mounted on an axis, and owing to the limited space, turned by hand. The wire reels were mounted on deck and the wire fed through the manhole. After completion of the winding the form was firmly braced into position, so that it became, as far as possible, an integral part of the framework of the vessel.

The coil had 5145 turns, average length of each turn 10.3 ft. corresponding to a circular diameter of 3.29 ft. The volume of the winding, V_3, was 2.6 cu. ft.

The balancing coil, C_3, was located inside the radio room of the chaser, which was used as the center of control and observation. Its location is shown at 0. Several different balancing coils were used at various times. They were all of small size, less than 1 ft. in diameter and were mounted in wooden frames, permitting accurate adjustment about a diameter as axis. Sometimes two coils were used, one of them located near the magnet to take up the greater part of the electromotive force in the detecting coil. The final balance, both as regards phase and magnitude of the net balancing e.m.f., was always accomplished from the observer's station, from which ready access could also be had to the rectifying commutator on the motor generator.

Practically all of the control equipment, including transformers, filters, condensers, switchboards, speed control and storage batteries, was located in the magaazine. The amplifier and resistance for the final adjustment of the balance were located in the radio room in convenient reach of the observer at 0.

All of the wiring was enclosed in steel conduit or other metal covering and all portions of the detecting circuit, transformers, speed control, etc., were placed in iron boxes for screening. Extreme precautions of this character were necessary, as any exposed part of the detecting circuit would pick up inductively stray disturbances difficult to recognize, and very troublesome when magnified by the amplifier.

Total Weight. The approximate weights of the several portions of the equipment are as follows:

Magnet,	420	lb.
Motor generator and control,	2000	"
Detecting coil,	1065	"
Amplifier,	150	"
Batteries and auxiliaries,	500	"
Total,	4135	"

As assembled, the only portion of the equipment appearing above decks was the magnet, whose housing was 10½ ft. long and approximately one foot square in section. The space occupied below decks was limited to the magazine, the radio room, and a part of the forehold.

The Tests. The experiments embraced a great many preliminary tests on the conditions and stability of the balance in the detecting circuit. The congested condition in the magazine, bringing as it did, the generator magnet, transformer and speed control in close relation to each other, introduced a number of new

disturbances. In addition, the motion of the boat, both as regards its vibration and rolling, were new types of disturbance. The phase of the magnetic field was found to vary in a most irregular way in different parts of the boat. Although the input transformer of the amplifier was enclosed in a triple nest of wrought-iron screens, it was found to pick up very large inductive electromotive forces. In some positions of the magnet M_3 these stray electromotive forces were so large as to be comparable in magnitude with that in the detecting coil itself.

As a result of all the new disturbing factors, the use of the input transformer was abandoned in the later tests and the amplifier operated at either three or four stages. Under the best conditions available on the boat therefore the sensitivity of the detecting circuit was reduced to from one-half to one-tenth the value used in the shore tests, depending on the motion of the vessel due to the sea. It was considered that this degree of sensitivity was surprising and highly satisfactory for the conditions encountered. It was accomplished largely through the reduction of the electrical equipment to its simplest terms, by careful spring suspension of the amplifier, the rigid mounting of the detecting and balancing coils and of the magnet, and especially to the close control of the speed of the motor generator.

It should be stated at this point, however, that the degrees of sensitivity, mentioned above, pertain to what would ordinarily be described as good sea and weather conditions. Motion of the boat in high wind and heavy sea is immediately reflected in the detecting circuit. Sudden changes in engine speed and sharp changes of course also introduced corresponding upsets of the conditions of balance.

The detection tests were made on the steel converted yachts Wasp and Vega. The dimensions of the Wasp have already been given. The Vega was 179 ft. long, 20 ft. beam and approximately 15 ft. depth from keel to rail top. The thickness of her skin could not be ascertained, and it is assumed to be the same as that of the Wasp, 5/8 in. The tests were made sometimes with the vessel to be detected lying at the dock and sometimes in the open waters of Chesapeake Bay. Three kinds of tests were made; one approaching the submarine end on, that is, along the common axis of the two vessels; one passing the submarine, the two axes being parallel; and the third approaching the submarine as though to ram her amidships. The distances of detection were read with a range finder, or "stadimeter," the observer standing close to the magnet M_3 The distances were measured to the center of the vessel to be detected. Two observers were required for making a test, one on deck measuring distance to the vessel to be detected, and one below at the instrument table. The detecting circuit was balanced with the vessel under way, and at some distance from the vessel to be detected. As the latter vessel is approached the galvanometer deflects and at a given magnitude of deflection the observer at the nstrument signals with a bell to the other on deck who records the distance. A great many tests of this character were made with various relative positions and speeds of the two vessels. It is not possible to make a more extended description of these tests within the limits of this paper.

The actual distances of detection reached, even under the best conditions, were usually somewhat short of 200 ft. In quiet water and at low speeds it was found to be possible to reach distances better than 200 ft., but this figure pertains strictly to conditions of this character. These figures fall somewhat short of the distances as computed for the equipment as installed. Two causes were found for the discrepancy.

At distances of 200 ft. between magnet and submarine the magnetic field due to the magnet is far from uniform over the whole length of the submarine. This results in a considerable shortening of the magnetic moment due to the hull of the submarine. A separate laboratory study of this condition showed that when a correction is made on this account, the observed distance of detection of 200 ft. is very nearly in accord with the computed distance.

A far more serious limitation to the distance of detection was found in the conditions of the balance, that is, in the instability of the zero of the detecting instrument. These conditions were strictly dependent upon the stability of the vessel and became rapidly worse the higher the sea, the more rapid the speed of the boat, and the balance was always sharply upset on any change either of the course or the speed. There was always available a considerably higher sensitivity in the combination of amplifier and galvanometer than it was possible to use, owing to the vibration and motion of the boat.

Considered from the standpoint of quiet water and slow speeds, the results of the detection tests on S. C. No. 326 were in accord with predicted values and they may be made the basis for the computation of the size of an equipment for extending the distances reached in the tests given above.

General Conclusions

The principal conclusions from the detection tests are as follows:

1. Detection tests in the laboratory with submarine models 10 ft. long are in agreement with underlying theory and may be used as a basis for the design of larger equipment.

2. Detection tests on steel hulls from shore equipment and from equipment installed on a wooden submarine chaser 110 ft. long are in good agreement with results predicted from a formula developed in the laboratory tests.

3. By sufficient increase in the size of the equipment it is possible, in quiet water, to detect a steel ves-

sel 200 ft. long at a distance of 500 ft. The weight of equipment required would be about 8000 lb.

4. Distances of detection in the neighborhood of 200 ft. were obtained in quiet water with equipment weighing 4500 lb. installed on a wooden submarine chaser 110 ft. long.

5. The reliability of the system of detection is immediately impaired by motion of the vessel, due to her engines, heavy sea, and changes of course, or speed.

6. The results mentioned involve the use of amplifier tubes for enlarging the signal. Without the amplifier the distances of detection are very short, even when a large magnet or large detecting coil and an extremely sensitive detecting instrument are used.

7. With amplifier, detecting coil and detecting instrument higher sensitivities may be reached than can be used in the detection tests. Disturbances in the detecting system fix the limit for increasing sensitivity. These disturbances are amplified and appear in the detecting instrument as larger than the signal sought.

8. The problem of increasing the distances of detection is that of eliminating disturbances in the detecting circuit.

9. Other interesting conclusions at various stages of the work will be found in the several appendices.

[To be concluded in the April Journal.]

The Engineer, Employer and Employee

BY CALVERT TOWNLEY

President, American Institute of Electrical Engineers

THE purchase prices of most essentials, not to mention luxuries, of life are now abnormally high. Can the engineer do anything about it except pay and grin? My good friend, George F. Swain, of Boston, says that the engineer is the antithesis of the idealist and that the idealist is a most dangerous individual. The engineer approaches a problem with an open mind, first obtains all the available facts and then reaches his conclusion and bases his action on these facts. The idealist on the contrary, first pictures the ideal result which he would like to obtain and proceeds to make his facts fit—if they do not, so much worse for the facts. In discussing higher prices, let me see if I can qualify under Professor Swain's definition of an engineer. The first question that arises is "Why are prices high?" And the answer to this question is almost if not quite obvious. Prices are high because costs are high and costs are high because wages have gone up. Of course material as well as labor goes into cost, but material in the last analysis is very largely labor because, for example, coal, iron, copper, lumber and other raw materials, forming the bulk of those used, are governed as to their cost by the wages paid to produce them. It is also alleged, and with reason, that prices of some commodities are higher than the increased costs justify because their distributors have taken advantage of existing conditions to reap abnormal profits. This no doubt is so to a limited extent. It can hardly be claimed to be true in general and certainly not to such an extent as to disprove the statement that prices are high because costs are high. Following the analysis, if prices are high because costs are high and costs are high because wages have increased, the next question is "Why have wages increased and in what way, up or down, may wages be expected to change in the future?" We have all heard much about the "awakening" of labor and its determination to hereafter demand and obtain a greater "share in the reward of its products." Our recent history is not lacking in examples of efforts on the part of workmen to benefit through organization and collective bargaining, effects crowned with no mean measure of success, but of catch phrases and slogans it perhaps may be said that they lack a sufficiently definite meaning to be interpreted alike by all. A catch phrase can frequently be made to mean whatever its user wants it to mean over wide limits. Let us therefore adhere to a terminology of which the meaning is understood by all and which is always the same. First of all what do we mean by "labor" and "capital?" Perhaps we all ought to understand what these words mean but do we? If we say that "labor" is the performance of manual work and "capital" is accumulated money, it can be pointed out that many are classed with labor who do no manual work while a large number have accumulated money who are not capitalists. Possibly the walking delegate's definition would be that a laborer is one who works all the time for pay but never has any money and a capitalist is one who has money all the time but never does any work. Both of these are manifestly incorrect definitions. For the purpose of avoiding misleading terms perhaps we can dodge the issue by not using them in the present discussion and instead of referring to capital and labor speak of the "employer" and the "employee" although even then it becomes necessary to explain the term "employer" to include not only him who pays for the services of others with his own money but also him who directs the work of others while himself employed and also to limit the term "employee" to those who do not so direct the

Presented before the Schenectady Section of the A. I. E. E., February 6, 1920.

work of others. Is there any good reason to believe that a "new order" of things has been created that the working man or employee will hereafter "demand" and what is more to the point obtain a greater share of the reward of his labor and that therefore wages and consequently the cost of everything into which labor enters will stay up and may even go higher? Has there been anything which may properly be called an "awakening" of labor? The only evidence that I can find to support such an idea is the undeniable fact that beginning in 1914 the employee has demanded and has obtained a greatly increased wage and of course we know it is human nature to get all we are able and to keep it if we can. But these plain facts do not prove the reasons why. The working man like every other man has in the past always wanted all he could get and human nature to-day has neither gained nor lost cupidity. There is no indication of a "new order" in these facts.

It is conservative to look for ordinary and natural causes before evolving new theories so before wondering whether there is or is not any "new order" of things, suppose we examine the old order and see what could be naturally expected under it. Before the war the country was prosperous, general business was good, the employees if not contented and happy were at least much less discontented and unhappy than they are to-day and with wages very much lower than they now receive. Then came the war. The men of both sides threw down their tools and took up arms. The productive capacity of every warring nation was at once greatly reduced but their needs were not—they were greatly increased, and naturally the United States was called upon to help supply them. We were by no means the only but we were certainly by far the largest source of supply in the world and our productive capacity was immediately speeded up to meet the new and unusual demand made upon it. All this was natural, ordinary and logical and its analysis so simple as to seem very obvious. Then what happened? The business men of this country—the employers— those in command of industry saw their chance. They had, if not exactly a monopoly or corner, in the supply market at least something very like it and they promptly took advantage of the situation and boosted their prices. Higher prices for export to Europe soon reacted to cause higher prices at home and the complaint of profiteering started and spread. It reached such proportions as to influence the government and action was taken to curb the business man's cupidity and make him loosen up. To a considerable extent he did it; sometimes with not very good grace, but nevertheless as a class he recognized the logic of events and acquiesced. Then we got into the war ourselves and we likewise took several million men out of our shops to fight and in turn we increased our demand for manufactured goods and decreased our productive capacity. You will note that I say "productive capacity" not our output. That our actual output was greatly increased in spite of the reduction in capacity is history but the reasons for it were improved efficiency, concentrated effort etc., and do not contradict nor weaken the preceding statement. Well, what happened then? Why the workman—the employee—waked up. He began to do what the business man—the employer— did when the war began, and which caused the hue and cry against profiteering. He saw a diminishing supply of men and an ever increasing demand for work and he cornered his market. He put up the prices of his services and having got the new price easily he put it up again, and so on. You know the rest. Now all this seems to be natural, simple, logical and so obvious as not to need argument but it is all based not on any "new thought" or on the awakening "of the proletariat" or any other new ideas or theories but on the plain old fashioned simple law of supply and demand, a law as old as the hills and just as immutable.

I do not lose sight of the fact that the organization of labor played a conspicuous part in bringing about increased wages. Many people no doubt honestly believe that organization did it all. Well organization did a great deal of course. The organization was the machine tool or weapon which the employees used to get quicker and greater results. It is pertinent to remember however that the organization of workmen is not new. They have been organized for years. There is no essential difference between the way in which nor the extent to which they are organized now and what they have been for many years past. And ever since employees began to organize they have been trying to get higher wages by identically the same methods they have been using during the war period. But organization never before accomplished anything like the results which latterly have been brought about and it seems clear therefore that we must seek the cause for the great wage advances not in some old condition like organization which existed long before the war but in some new condition that has been created since the war began. That new condition is obviously a change in the relation of supply and demand and we get back to our first conclusion again as to why wages have so greatly increased. Another contributory cause is the decreased efficiency of the workman. Employees. as a class, do less work, produce smaller results per day's work than formerly. There seems to be abundant evidence of this condition; enough to warrant our accepting it as a fact. One reason of course is that the employers had to use "seconds." Just as a builder in times of stress will put into a house lumber that he would ordinarily reject; because he cannot get enough first class lumber and he *must* have the house, so employers were forced to hire men in war time that ordinarily they wouldn't have about the place; there weren't enough others. Then of course there is the question of fewer hours per day and a reluctance to work continuously through the week. These features materially affect the increase in cost. They effect it tremendously

but while in fact they may be important, they nevertheless are not causes at all but merely results incidental to the working out of the law of supply and demand. They are superimposed upon and do not underly the existing condition which we are analyzing.

Some say that the change in the value of the dollar has caused the increased cost. On all sides we hear and read the statement that the dollar is only worth fifty cents, or some other small fraction of its face, and that prices and wages are really no higher than they used to be because the dollar is now worth much less. Well suppose we briefly examine that statement. What is a dollar worth anyhow—by itself? Why a dollar isn't worth anything—by itself. You can't do anything with it—by itself. A dollar is simply and solely a convenient medium of exchange. It has become valuable just to the extent that men want it and will give up something which they have to get it. When we set out to place a definite value on the dollar in commodities or labor it isn't sufficient to take into account the conditions in one place only, in Schenectady, for example, or in a dozen or in fifty places, or even in any one entire country. The dollar has value all over the world now but when our economists insist that the value of the dollar has fallen permanently, they are evidently thinking in terms of conditions in the United States only. Abroad the situation is very different. A dollar will buy about six shillings in London, 1½ times its old rate; 15 francs in France, three times its old rate; 100 marks in Germany, 24 times its old rate, and the end is not yet. Travelers returning from Europe bring back specific information of how much more than formerly can now be bought with a dollar. Not only is foreign money cheaper but things are as well. For example in November last at the best hotel in Vienna, and its a good one too—the Hotel Bristol, a big room with three beds and a bath, occupied by three, the rate was the equivalent of 62 cents a day American money. Does that look like a depreciated dollar? And if it be said that this comparison is misleading because European exchange is only down for a while and the condition is therefore temporary, the answer is how do we know, how does anybody know that the values in the United States are any more stable or permanent? Instead of theorizing why not look to history for real information? The best indication of what will happen in the future is what has happened in the past. We have had wars before—not so big, not so many men were killed, but a very similar condition as to the supply of and demand for labor was created. This same condition of inflated values that confronts us now existed right after our civil war and it seems reasonable to attribute it to the same causes. In any event the high cost of living after the civil war was not due to the activities of labor organizations because they didn't exist then. The more we examine the cause for abnormal advance in wages from different angles the more it seems evident that the fundamental underlying and controlling cause has been an increased demand and a decreased supply. Now if the law of supply and demand has controlled the wages of workmen in the past and through them the cost and therefore the price of commodities, this same law is very likely to exercise this same control over the same conditions in the future. In other words prices will stay up, go higher, or fall according as the supply of labor is equal to, less than, or greater than the demand. You will have noted, I hope, that I have tried to discuss facts and conditions and have not referred to the so called "rights" of the interested parties, the employer, the employee and the public. That is another part of the story but it is my conception that the economics of industry will continue to be governed by economic laws which are just as immutable as are the laws of the attraction of gravitation and other physical laws albeit not so generally understood and acknowledged and that any so called "rights" of the different elements of society, no matter how skillfully or persistently asserted, must give way absolutely before the inexorable operation of economic laws. The question of "rights" is further one into which opinion enters more than demonstrable facts and no opinions of any party to such a discussion has received particular credence, much less acceptance from any opposing party. It would be profitless therefore in the present discussion to diverge into any attempted examination of this phase on the subject.

If now prices were raised to their present level because the war required greatly increased production and at the same time withdrew from productive occupations so large a number of workers, how will prices be affected by the operation of economic laws in the future? The war is over. War material is no longer demanded. Its production has ceased. The men who fought have been released to pursue again their pre-war avocations. Yet prices are still up where they were. If my reasoning is correct, why has the law of supply and demand not reversed its effect and operated to restore pre-war conditions? That question has to be asked to follow the analysis logically but its answer seems fairly obvious. Pre-war conditions have not been restored because there hasn't been time. In this country during the war we couldn't and didn't produce what was needed. We produced all we could selecting the things most essential —war material. Industrial needs had to wait. Now the country is catching up. Our stimulated productive capacity has been diverted from war to peace channels and a booming business still struggles to meet the demand made upon it. In Europe the conditions are similar but more acute. Industry was put out of joint there worse than here. It will take Europe longer to recover and readjust, meanwhile some of their immediate needs must be supplied from this side and this requirement puts an added demand on us and still further defers our return to a pre-war normal status. New nations have been created—financial and many other problems demand solution, all taking time and

yet more time, and keeping the United States still working extra hours. Although the supply of workmen has been greatly augmented by demobilization the peace demands have absorbed this supply and as yet there is no surplus. Many people say there never will be a surplus. That the United States has taken up a new place in the world's industries and henceforward will be expected to produce and will supply a so much larger share of the total world's commerce than ever before that our industries will be kept going at top speed and every workman be busy. This is certainly an optimistic picture. It is worth examining. Europe owes a lot of money. Some of their men have been killed. In the war zone the country was laid waste. These are the only real differences between then and now. Their abilities are no less, their natural resources are intact, their morale is good. Europe competed with us before the war and although we set up a tariff wall around our own country and successfully protected our domestic business she captured most of the world's trade against our best efforts. Of course we now have certain advanvantages we did not possess before. We are a creditor nation and can exert the influence attaching to that position. We have made tremendous inroads into Europe's foreign commerce while she was down and out commercially and we have thereby established relationships and gained an entree previously denied to us and which if judiciously followed up should produce results of great value. But the European nations are not out of the running permanently. They must recover a large volume of trade or go bankrupt. They are diligent and by nature and training thrifty. They will work under the spur of necessity. We are naturally spendthrifts. We are inclined to overconfidence. When the world's productive capacity shall have caught up with the industrial shortage occasioned by the great war and the demands of commerce shall have again become normal and when Europe's industries are once more functioning properly, it seems reasonably certain that there will be an excess of production over consumption and some nations will lack a market. Translated to workmen, this means that the supply will be greater than the demand and some must go hungry. It will be then that the test will come. If the United States shall have used the prosperous period to prepare for it by reducing the costs of production and by teaching its people economy and thrift the readjustment may come perhaps without any serious disturbances and we may save a good share of what we had gained by our running start. But if we sail serenely on ignoring the possibility of a coming storm, if we continue the policy of working less and less and of paying more amd more while Europe buckles to, the resulting depression with its period of unemployment, suffering and possible panics is appalling to contemplate. Then prices and wages will come down suddenly and with a thump—such a thump as the country has never known. The inexorable law of supply and demand is no respector of people or nations and its deadly work will be deadly indeed.

We now come back to the question I asked in the first place, "Can the engineer do anything about it except pay and grin?" I think he can. An engineer is by training taught to think straight and to speak clearly. Further it is a fixed tenet of his faith to tell the truth and fear none. People know that and believe him. If I have been fortunate enough to have made my views clear to you and if you agree with me, say so, and keep on saying it as you go about your daily tasks. Do what you can to show up the idiocy of dwelling in a fool's paradise and preach the gospel that industrial preparedness is as essential to commercial safety as military preparedness is to national safety. Dispel the bogy of class control. Brains always have ruled the world and brains always will. Show that we are dealing with a perfectly normal problem which must be solved in conformity to well-known natural laws and not with any mysterious unknown or novel principles or with newly discovered rules of life. No organization of a minority created for the avowed purpose to taking from the majority some of its property or just rights can long prevail. Witness organized Germany's effort to subjugate the world. The law of supply and demand will ultimately just as surely bring down the cost of living and the wages paid employees as it put the items up. The only uncertain features are the time when the changes are to occur and whether these costs and wages shall be brought down in an orderly and gradual manner so that the readjustment shall be made without disturbance and with lasting benefit to all or whether they shall come down with a thump, heard around the world, amid disaster and distress.

This is one of the most important problems confronting our great nation to-day. As citizens it concerns us all. As members of the A. I. E. E. who have enjoyed the privilege of special training and of valued association with our fellows we have each a duty to perform. It is perhaps as well stated as may be on the old familiar railroad crossing sign, "STOP, LOOK, LISTEN."

Changing 33-Cycle Apparatus To Operate on 60-Cycle Circuits

BY D. W. PROEBSTEL
Assistant Engineer, Portland Railway, Light and Power Co.
AND
E. H. LeTOURNEAU
Secretary, Portland Railway, Light and Power Co;

BEFORE dealing with any of the specific problems involved in changing 33-cycle equipment to 60-cycle operation, it would be well to review a few historical facts which were responsible for the two frequencies now in use on the system of the Portland Railway, Light and Power Company of Portland, Oregon.

In a paper, read by Mr. F. G. Sykes before the Electrical Transmission Section of the Pacific Coast Engineering Congress held at the Lewis and Clark Centennial Exposition, June 29 and 30, 1905, are many references to the early development of the electrical industry in Portland. This article gives the following information: The first contract for city lighting was taken March 18, 1885, and at Weidler's Mill in North Portland a brick building was erected to house the boilers, engines and dynamos. In 1887 this plant was enlarged by the addition of five 750-light, 1000-volt Westinghouse alternators, with a frequency of 125 cycles. The following year, on November 8, 1888, the Willamette Falls Electric Company was incorporated, and all of the Weidler Mill equipment, except the original five Westinghouse alternators, was moved into Station A, Oregon City. In 1889 the equipment in the Willamette Falls power plant consisted of six Westinghouse 80-kw., 125-cycle, 4000-volt generators and two Thomson-Houston 120-kw. 125-cycle, 2000-volt generators and eleven 100-lamp, Excelsior arc machines, the lamps being rated at 2000 c. p. Each of these nineteen machines had its individual circuit into Portland, a distance of approximately fifteen miles.

The growth of the electric railway system in Portland in 1893 demanded a new order of things. Direct current in larger quantities was needed. The synchronous converter operating at frequencies in the neighborhood of 25 to 30 cycles had been successfully built at this time, and with the view to supplying direct current for railway service through the use of such apparatus and on account of that frequency being well adapted to the economic speed of the water wheels, the frequency of 33⅓ cycles was adopted when the new plant on the west side of the river at Oregon City was constructed. This frequency was also expected at that time to prove successful in the operation of a-c. arc lamps. Four sections of the Station B plant were built at that time and four 450-kw., 200-rev. per min., 33-cycle generators were installed with separate lines to Portland, two of which operated 400-kw. synchronous converters located in the basement of the office of the Portland General Electric Company at Seventh and Alder streets.

It was some years after this that there was a demand for 60-cycle service in Portland for light and power. This frequency was obtained by regeneration, using frequency changers. Two 500-kw. sets consisting of 33-cycle motors direct connected to 60-cycle generators were first installed and were followed later by several 1000-kw. sets.

The first direct generation of 60-cycle electric energy of importance was in the summer of 1908, following the disaster at the Cazadero hydroelectric plant of the Company. Since that time the 60-cycle load has gained so rapidly that nearly all of the generating and transforming equipment installed during recent years has been designed for 60-cycle operation.

On page 55, Volume 37, of the A. I. E. E. TRANSACTIONS will be found an article by Mr. B. G. Lamme entitled "The Technical Story of the Frequencies." He mentions a few of the frequencies that have been in use in this country such as 133⅓, 125, 83⅓ 66 ²/₃, 60, 50, 40, 33⅓, 30, 25 and 16²/₃. Several of these earlier frequencies were a result of convenient construction rather than of design. For instance, it was convenient to build a generator for a speed of 2000 rev. per min. and 8 poles. This gave 16,000 alternations per minute or 133⅓ cycles per second.

It had for a long time been recognized that the operation of the system with two different frequencies was disadvantageous. Sixty-cycle generators could not be used to operate 33-cycle motors or synchronous converters except through frequency changers with the consequent loss and the inflexibility due to location and size. Neither could 33-cycle generators be used to furnish the energy required by 60-cycle motors. Duplicate transmission lines had in some cases to be built where one might have served if there had been one frequency only, and there are many other reasons why a single frequency is desirable.

In the spring of 1918, due to the increase in load brought on by the war industries, the company was confronted with a situation where it was necessary to secure additional 60-cycle generating capacity. It had 33-cycle generating capacity rather in excess of the needs, but even though the frequency changers could be considered as available as 60-cycle generators,

Presented at a meeting of the Portland Section of the A. I. E. E., October 7, 1919.

there was still need for additional 60-cycle current capacity to take care of the increases in the 60-cycle war industries load.

Mr. O. B. Coldwell, the company's General Superintendent, went East to determine what could be secured to meet the needs of the situation. As a result of the investigations made on this trip, it was decided to change the largest one of the company's generating units from 33 cycles to 60 cycles in a unique way.

The machine involved in the change was installed in 1912 and was a two-pole 7500-kw. 1980-rev. per min., 33-cycle, 5500-volt generator direct connected to a six-stage horizontal Curtis turbine The generator winding was star-connected, and was operated with grounded neutral. The station bus voltage of 11,000 was obtained by the use of a 2 to 1 ratio, three-phase 5114 kv-a. auto-transformer.

The method which was decided upon, of changing the generator from a 33- to a 60-cycle machine was to change the polarity of one of the two field poles, making both of the same polarity and causing two poles of opposite polarity to be induced at 90 deg. to the wound poles, and to reduce the speed of the machine from 1980 to 1800 rev. per min. The stator winding required changes in connections, but it was not found necessary to remove the winding from the slots. The two-circuit star-connected winding was changed to a single-circuit star-connected winding. It was also necessary to change the connections and ratio of the auto-transformer to provide for changing the generator voltage of 7000 to the bus voltage of 11,000. (Fig. 1.)

When the change to 60-cycles by inducing two poles was suggested, it was recognized by the manufacturing company's and operating company's engineers that poles would not only be induced at 90 deg. to the poles set up by the wound coils in a plane perpendicular to the axis of rotation, but that there would be a certain amount of endwise or axial flux, caused especially by the flux linkages with the end turns on the rotor. Therefore, it was suggested that compensating coils be placed at the ends of the rotor concentrically with the shaft in such a way as to oppose or counteract the endwise flux. The General Electric Company's engineers designed such compensating coils each to be composed of 66 turns of 0.1-in. by 2-in. flat ribbon copper mounted on the inside of the inner end shields. To check up the requisite number of ampere turns in the compensating coils, as well as to confirm the prac-

ticability of the converted machine, the manufacturers made a test on a much smaller machine at the factory. They changed a two-pole machine of much the same characteristics as the 7500-kw. machine into a four-pole machine by inducing two new poles. The results of their tests were not available until after the change was actually made in the 7500-kw. unit at Portland, but they also demonstrated that the idea was practicable. It was found in the case of the test machine that the compensating coils were not needed, but this apparent result may have been due to the fact that the machine was not run long enough to develop trouble. In any event, as will be seen later, they certainly proved necessary in the case of the larger machine. The wave form in the case of the four-pole operation of the test machine was as would be expected from the field form, different in its two halves, the top of one-half being flat while the other half was more peaked, higher, and showed the steps caused by the rotor slots.

The change-over to 60 cycles on the 7500-kw. unit at Portland was started in July, 1918. The work was completed including the installation of the compensating coils. Considerable difficulty was encountered in securing the copper for these compensating coils and it was finally obtained from a manufacturing jeweler, who rolled the copper to size in lengths of about 20 feet and made it into one continuous piece by means of silver soldering. The winding of the coils proved a difficult process on account of the copper being drawn out of shape in the rolling. When the machine was started up and cut in as a 60-cycle machine, it operated satisfactorily for a couple of days, carrying loads up to 5000 kw., when troubles commenced. The fifth-stage runner in the steam turbine became loose on the shaft and shifted endwise, causing it to rub on the stationary vanes and necessitating the removal of the intermediates from this stage. After this was done and the machine started again, it developed an excessive vibration and the coupling between generator and turbine was trued up in an endeavor to improve the balance. This did not however remove the trouble and various other experiments were made to improve its operation, such as changing the turns and current in the compensating coils and lowering the stator to increase the air gap on the bottom, with the idea of compensating for the increased magnetic paths, due to the bed plate. None of these experiments however was instrumental in entirely removing the difficulties, and during the fall of 1918 when the generating capacity of every plant on the system was required to carry the imposed load, it was not possible to take the machine out of commission long enough to make a thorough investigation into the causes of the trouble, even though it was only possible to operate it at loads not exceeding 2500 kw. and although it vibrated excessively. However, as soon as the winter rains brought water to the hydraulic plants and the steam plants were relieved, the machine was given a thorough overhauling. It was and is appreciated that if the machine could have been overhauled as soon as the first troubles developed, a number of the repairs later necessary might have been avoided. The fifth-stage intermediates were restored and wheel shrouds repaired, the shaft was trued up, bearings rebabbitted and scraped, the field coils and compensating coils reinsulated and the machine put in first class condition. While the turbine was being overhauled, tests were made on the revolving field to see if poles were balanced. These tests revealed that some turns were short-circuited. It was found that the end turns had become distorted and the insulation had been cut on one of the straps connecting the bottom of one series of coils to the top of the next. Repairs were made by driving sheets of hard mica between the straps and the coils. The distortion of the coils was apparently caused by the action of centrifugal force because of insufficient wedging between coils. (See Fig. 2). This failure when discovered was considered entirely responsible for the vibration of the machine, but other difficulties were found later.

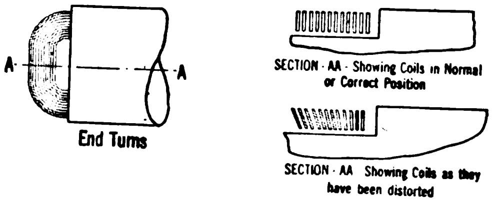

FIG. 2—SKETCH SHOWING FAILURE IN FIELD WINDING ON 7500-KW. TURBINE

The machine was carefully balanced and tried again, but after operating a short time with field circuit closed, it developed its former tendency to vibrate excessively. It was tried at first with no current in the compensating coils, inasmuch as the General Electric Company had not found it necessary in the case of the test machine. Then a separate machine was provided to supply current to the compensating coils and trials were made with various ratios of current in field coils to current in compensating coils. During some of these tests, it was discovered that the insulation between the outboard bearing pedestal and bed plate had broken down. This was repaired, and in trying out the mechanical balance, it was found the governor drive gear which was mounted on an end of the main shaft was not running exactly true and caused some unbalance. The end of the shaft was then ground in the bearings and the governor drive pinion bushed to fit by electrically welding on material and reboring. This improved the mechanical balance but the vibration reappeared when operated for any length of time with field circuit closed. An examination of the bearings showed that apparently electric action was taking place. During the investigation of the electric action in the bearings, a brush was placed on the shaft between the middle bearing and the rotor and electric-

ally connected to the bearing pedestal. Within a very short time after the field circuit was closed, the ½-in. bolt connecting the brush to pedestal melted off, showing that an enormous current was flowing, Following this, careful readings of voltage were taken between the shaft and pedestals on all bearings and from pedestal to bed plate on the insulated bearing, under various conditions. By varying the current in the field coils and compensating coils, it was found that it was possible to materially vary the voltages between shaft and bearing pedestals. The voltage readings were taken with a d-c. voltmeter and tests showed that there was practically no alternating voltage under any of the conditions. When the current in compensating coils was reversed and the resultant flux augmented instead of opposed the endwise flux from the field coils, the voltage between shaft and bearing pedestal was very materially increased. By experiment, it was found that with flux set up by current in the compensating coils opposing the endwise flux caused by excitation of the field poles, increases in current in compensating coils up to a certain point tended to decrease the bearing voltages, and any given

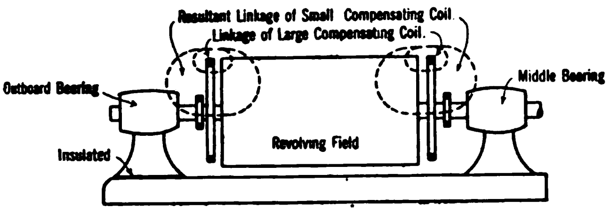

Fig. 3—Sketch Showing Magnetic Circuits of Compensating Coils

field excitation and increases beyond that reversed the bearing voltages.

It was apparent therefore that there might be a certain ratio of compensating coil current to field current which if maintained might keep the bearing voltages below an allowable maximum. This was found to be the case but the ratio was found to be so great that the required compensating-coil current corresponding to full-load field current was larger than the coils would carry continuously. It was further apparent that the compensating coils were not fully effective in doing that for which they were designed. A diagrammatic illustration of our conception of the flux linkages is shown by a sketch. (See Fig. 3). The bearings were acting as direct-current generators, because the shaft was cutting the magnetic lines of force which used the shaft and bearing pedestal as part of the magnetic circuit. The compensating coils as at first designed were evidently not sufficiently effective in opposing the flux in the shaft.

From a study of the theoretical considerations involved, it was thought that compensating coils closer to the shaft would be much more effective. Some experiments made with coils of cable wound on the outside of the inner shield indicated the correctness of the assumption and consequently additional coils were designed to be placed in series with the already installed coils, and to be located near the shaft. It was found to be difficult to find space in which to locate the coils, but by winding one of the coils in place on the machine, the other being wound in the shop, the desired 19-turn coils were constructed and installed on each end. The location of the coils is illustrated in a sketch. (See Fig. 4). All of the compensating coils are operated in series and in series with the field coils, thus main-

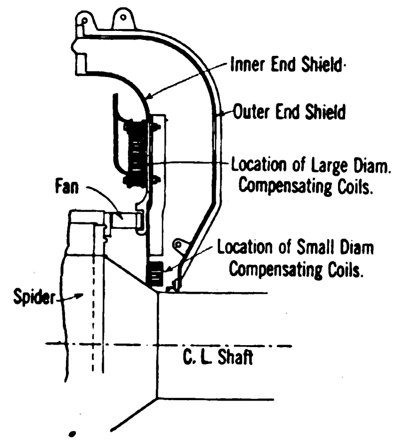

Fig. 4—Sketch Showing Details of End Shields and Compensating Coils on 7500-Kw. Turbo-Generator—Station E

taining proper ratio of ampere turns for all values of field current. The ratio was computed for unity power factor conditions, but it has been found that under any conditions of operation, the voltage on the center bearing where the effect is most marked does not exceed 1¼ to 1½ volts. The operation of the bearings has been entirely satisfactory since the current in the bearings has been reduced and no further vibration has occurred. The wave form as shown by an oscillogram was practically sinusoidal. (See Fig. 5).

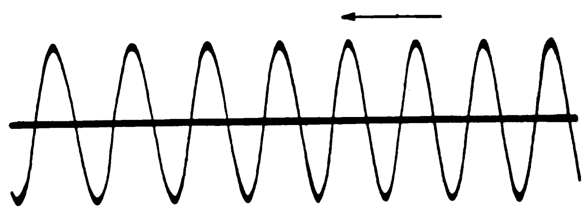

Fig. 5—Oscillogram, No. 5 Turbo-Generator—Station E—Generator, Open Circuit

As stated before, one of the reasons for the adoption of 33 cycles as a system frequency was in order that synchronous converters could be used, and a considerable number of these machines was purchased and installed to furnish railway service. When considering the problem of effecting economies through a reduction in the amount of 33-cycle apparatus, it was necessary to consider especially the 1000-kw. converters. It was not feasible to sell them and buy 60-cycle machines as there are very few systems on

which they could be used. Consequently Mr. Coldwell sought to solve the problem by changing the converters into 60-cycle machines. His preliminary analysis indicated to him that there was a chance of its being accomplished and he therefore had the matter gone into thoroughly. As a result a 1000-kw. converter has been converted from a 33-cycle to a 60-cycle machine by changing the number of poles from 12 to 18 and by increasing the speed from 333 to 400 rev. per min. The method of making the changes is described in the following:

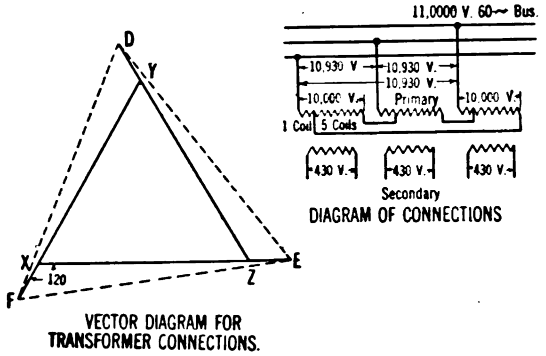

FIG. 6—THREE 10,000-VOLT AIR BLAST TRANSFORMERS CONNECTED TO OPERATE ON AN 11,000-VOLT BUS AND MAINTAIN NORMAL SECONDARY VOLTAGE

The synchronous converter under consideration in its original state was a 12-pole, 1000-kw., 333-rev. per min., 600-volt d-c., $33\frac{1}{3}$-cycle, six-phase machine. The armature core has 324 slots wound with two coils per slot making 648 coils. This number is not only a multiple of six (one-half the number of poles of the original machine) six, the number of phases, and 18, the number of coils per phase, but also a multiple of nine (one-half the number of poles of the new machine) six, the phases, and 12, the coils per phase. Changing from 12 poles at 33 cycles to 18 poles at 60 cycles increases the speed from 333 to 400 rev. per min., or an increase of 20 per cent. This was considered safe from a structural standpoint.

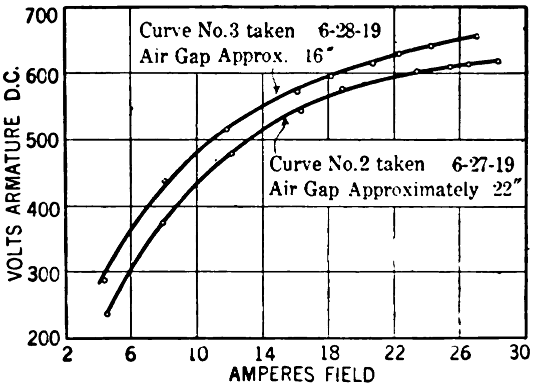

FIG. 7—SATURATION CURVES—60-CYCLE CONVERTER—SHOWING EFFECT OF CHANGE OF AIR GAP

The coils before the change occupied slots 1 and 26, etc., and in the rewinding were given a pitch such that they occupied slots 1 and 19, etc. It would be natural to expect an increase in flux density in the armature teeth, but the increase in speed prevented the flux from being as high as it would otherwise have been. The flux density in the armature teeth of the original machine at full load was about 138,000 lines per sq. in. and in the new machine about 180,000 lines.

The field poles, field windings and bridges for the changed over machine were designed and constructed by the General Electric Company, and the work of reconnecting the armature, changing the brush rigging, reassembling, etc., was done locally.

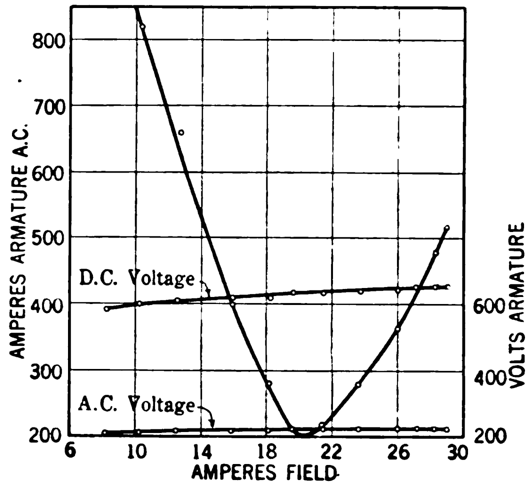

FIG. 8—PHASE CHARACTERISTIC CURVE—60-CYCLE CONVERTER

Work on rewinding the armature was started first. All the coils were taken off, cleaned, retaped where necessary and reshaped. The coils were put back in the slots with new slot insulation and new wedges, and reconnected with a pitch such that the coils occupied slots 1 and 19, etc. The connections from the collector rings would not conform to the new division of the coils, so six ring buses were secured to the spider on the a-c. end by means of fiber clamps and to these buses were soldered the connections from the collector rings and also those from the clips on the armature

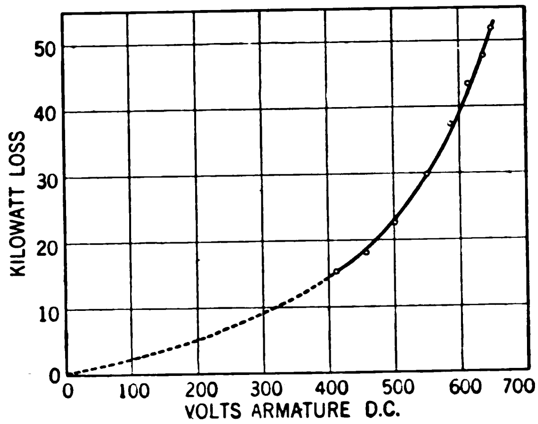

FIG. 9—OPEN-CIRCUIT CORE LOSS CURVE—60-CYCLE CONVERTER

windings, the connections, of course, being arranged in proper sequence. The final work on the armature was banding it with extra heavy banding wire.

The magnet frame was stripped of its original field poles and sent to a machine shop where it was bored out to a larger inside diameter and bolt holes drilled to receive the new pole pieces and field coils furnished by the manufacturers.

The brush holder ring was altered to support 18 brackets for brush studs instead of 12. This was accomplished by electrically welding two cast iron blocks on opposite sides of the ring, machining them to dimension and drilling. Extra brass brush holder brackets, studs and connection pieces were supplied to complete the d-c. brush rigging. After all the new and worked-over parts had been collected together, the assembling was accomplished with very little difficulty.

The air-blast transformers which form a part of the synchronous converter equipment have a voltage ratio of 10,000 to 430. The 60-cycle bus voltage is 11,000, so something had to be done in the way of

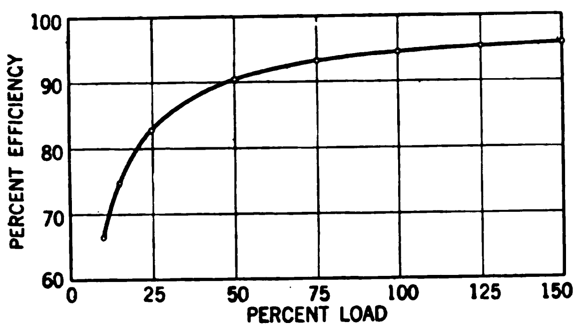

FIG. 10—LOAD-EFFICIENCY CURVE BASED ON AN ASSUMED RATING OF 1500 KW.

increasing the ratio between the primary and secondary in order to maintain normal voltage on the direct-current side of the converter. This was accomplished by a novel scheme of primary connections, shown in the accompanying sketch. (See Fig. 6.)

Testing of the newly assembled machine was the next step in the progress of the experiment. The first tests were the usual preliminary ones such as insulation tests on field and armature, cold resistance measurement of the field, drop on individual field coils and polarity test. Following these tests, a 60-h.p., 600-volt motor was belted to the converter shaft to drive it while under test. Saturation readings were first taken which showed that it was not possible to obtain a d-c. voltage in excess of 600 volts because of too great a reluctance in the magnetic circuit. Therefore, the air gap was reduced from 0.22 in. to 0.16 in. by inserting sheet iron shims between the poles and the magnet frame and another set of saturation readings taken. This change showed a very satisfactory improvement. (See Fig. 7). The converter was then started from the 60-cycle bus and brought up to speed. The brushes were adjusted for best commutation, and voltage readings taken on the a-c. and d-c. sides to determine the ratio of conversion. The ratio was about 71 per cent as was to be expected.

A phase characteristic test was made next and curves plotted. (See Fig. 8). The machine was then run without load and at unity power factor for ten hours and temperatures of the various parts taken. The inside of the field coils showed the hottest tempera-

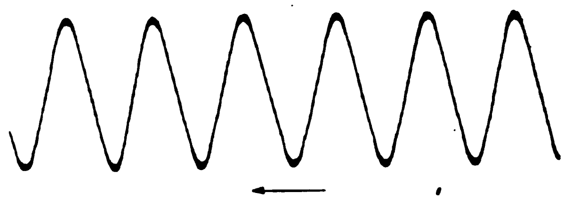

FIG. 11—OSCILLOGRAM, 60-CYCLE SYNCHRONIZED CONVERTER, REDUCED SPEED

ture to be only 64 deg. cent. It was next put in service on the railway bus and operated in the usual manner for several days. We then imposed a heavy load condition on it for eight hours, holding the power factor as nearly unity as possible and observed it closely. It remained comparatively cool and its commutation was excellent, notwithstanding the current varied from 1000 to 3000 amperes.

Determination of new rating and efficiency demanded a core loss test. (See Fig. 9). From this and the foregoing tests efficiencies were calculated on a basis of 1500 kilowatts as normal load. (See Fig. 10). A load of 1500 kilowatts was then held on the converter until constant temperatures were reached, then shut down and temperatures of all parts taken. The temperature in degrees centigrade of hottest spots were: field by rise in resistance calculation 61.5 deg., pole tips 56.5 deg., armature core 51.5 deg., air duct 54 deg., field coil inside 55 deg., and commutator 49.5 deg. The room temperature was 24 deg. cent. These temperatures were by no means excessive and it was concluded that the external wiring and transformers, rather than the internal heating of the converter, precluded a safe loading beyond 1500 kilowatts. Finally an oscillogram was taken of the voltage wave with the machine running as a generator separately excited from the railway bus. (See Fig. 11).

NATIONAL ELECTRICAL CODE

The Electrical Committee of the National Fire Protection Association will hold public hearings on the items appearing in its bulletin on March 23 and 24 in the Assembly room of the New York Board of Fire Underwriters, 123 William St., New York. Any member of the Association interested in electrical fire hazards is welcome at these hearings, and is privileged to speak. For copies of bulletin apply to Secretary Ralph Sweetland, 141 Milk St., Boston, Mass.

Mutual Inductance of Two Straight Cylindrical Conductors Which Lie in Parallel Planes but which are not themselves Parallel

BY ALBERT M. JACOBS

Electrical Engineer, Chile Exploration Co., New York, N. Y.

CONSIDER a symmetrical arrangement, *i. e.* supposing the planes containing the conductors to be horizontal then the horizontal projections of the conductors shall bisect each other.

It is assumed that the total length of conductor to be considered is contained between two parallel planes cutting one of the conductors at right angles.

That is, the field due to the current flowing outside of the length of conductor under consideration is assumed to have no effect on the conductors, *e. g.* if a generator be connected to one end and a motor to the other.

Let the vertical distance between conductors be s and the horizontal distance between conductors, measured in the end planes, be r. The maximum distance between leads is then $\sqrt{r^2 + s^2}$.

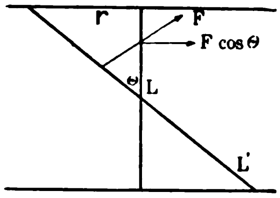

FIG. 1

Let the angle included between the horizontal projections of the leads be θ. Consider the action of the longer lead (of length L') on the shorter lead of length L. The component of the field F, due to L', which cuts L at right angles is $F \cos \theta$. The total field being proportional to L', the component cutting L at right angle is proportional to $L' \cos \theta$ *i. e.* proportional to L.

In the expression for M *viz.* $2L\left(lgn \frac{2L}{d} - 1\right)$ we may therefore use L instead of $L' \cos \theta$.

As d varies from point to point, the average value of $lgn \frac{2L}{d}$ has to be found. Taking the point of intersection of the horizontal projections as the origin, O, and the direction of the shorter lead as the abscissa axis, the ordinates will represent the horizontal distances between leads from point to point. The vertical distance being constant throughout, d may be expressed as the hypotenuse of a right-angled triangle.

The expression for $lgn \frac{2L}{d}$ is to be integrated between the limits O and $L/2$, the definite integral multiplied by 2 and the result divided by L to obtain the average value sought.

Let x = distance along shorter lead measured from O.
y = ordinate corresponding to x.
Then y is obviously proportional to x, *i. e.* $y = cx$

When $x = L/2$, $y = r$, whence $c = \frac{2r}{L}$

$$y = \left(\frac{2r}{L}\right) x.$$

Therefore $d = \sqrt{y^2 + s^2} = \sqrt{\left(\frac{2r}{L}\right)^2 x^2 + s^2}$.

$$\text{and} \int_0^{l/2} lgn \frac{2L}{d}\, dx$$

$$= \int_0^{l/2} lgn \frac{2L}{\sqrt{\left(\frac{2r}{L}\right) x^2 + s^2}}\, dx$$

$$= \int_0^{l/2} lgn\ 2L\, dx$$

$$- \int_0^{l/2} lgn \sqrt{\left(\frac{2r}{L}\right) x^2 + s^2\, dx} \qquad \textbf{(A)}$$

Consider the second integral. Omitting limits pro tem we may write it as:

$$\int \frac{d}{dx}(x)\, lgn \sqrt{\left(\frac{2r}{L}\right)^2 x^2 + s^2\, dx}; \quad \text{and}$$

integrating by parts this is equal to:

$$x\, lgn \sqrt{\left(\frac{2r}{L}\right)^2 x^2 + s^2}$$

$$- \int x \frac{d}{dx} lgn \sqrt{\left(\frac{2r}{L}\right)^2 x^2 + s^2}\, dx. \qquad \textbf{(B)}$$

Differentiating and multiplying by x we obtain finally $\frac{x^2}{\left(x^2 + \frac{s^2 L^2}{4r^2}\right)}$. Throwing this into partial fraction form we obtain:

$$\frac{1 - \frac{s^2 L^2}{4r^2}}{\left(x^2 + \frac{s^2 L^2}{4r^2}\right)}$$ in which form the integral may readily be written as:

$$x - \frac{SL}{2r} \tan^{-1} x \left(\frac{2r}{sL}\right).$$

(B) then becomes:

$$x\, lgn \sqrt{\left(\frac{2r}{L}\right)^2 x^2 + s^2}$$

$$- x + \frac{sL}{2r} \tan^{-1} x \left(\frac{2r}{sL}\right)$$

and **(A)** becomes, omitting limits,

$$x\, lgn\, 2L - x\, lgn \sqrt{\left(\frac{2r}{L}\right)^2 x^2 + s^2}$$

$$+ x - \frac{sL}{2r} \tan^{-1} x \left(\frac{2r}{sL}\right).$$

which may also be written

$$x\left(l\,g\,n\sqrt{\frac{2\,L}{\left(\frac{2\,r}{L}\right)^2 x^2 + s^2 + 1}}\right.$$

$$\left. - \frac{s\,L}{2\,r}\tan^{-1} x\left(\frac{2\,r}{s\,L}\right)\right)$$

For the lower limit, $x = 0$, this expression vanishes. Inserting the upper limit, $x = L/2$, and multiplying by $2/L$ we obtain:

$$l\,g\,n\sqrt{\frac{2\,L}{r^2 + s^2}} + 1 - s/r\tan^{-1} r/s.$$

which is the *average* value of $l\,g\,n\,\frac{2\,L}{d}$.

Inserting this value in the expression for M we obtain

$$M = 2\,L\left(l\,g\,n\,\frac{2\,L}{d_{max}} - s/r\tan^{-1} r/s\right).$$

The last term in this expression may be somewhat differently expressed. In the containing planes at the ends of the conductors the latter would appear as in diagram at side.

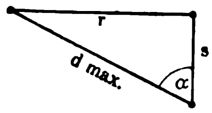

Fig 2

Now $s/r = \cot\alpha$
and $\tan^{-1} r/s = \alpha$
M may then be written:

$$2\,L\left(l\,g\,n\,\frac{2\,L}{d_{max}} - \alpha\cot\alpha\right).$$

If the arrangement be unsymmetrical *i. e.* if the projections of the conductors on a horizontal plane do not bisect each other the above method can obviously still be used by integrating between the correct limits.

For parallel conductors, r vanishes and α becomes zero. It may readily be shown that the limiting value of $\alpha\cot\alpha$ is unity, and the expression for M reduces to the standard value.

For conductors cutting each other at right angles r becomes infinite and M becomes zero.

The aim of this investigation was to develop an expression which could readily be used in practical layouts in which the values of r and s would be readily obtainable, rather than to obtain a general mathematical expression depending on the lengths of leads and the angle θ contained between the horizontal projections.

The value found for M is the average M of an infinite number of conductors running parallel to the shorter one and at all horizontal spacings between zero and r. The longer conductor may be considered as replaced by a conductor running parallel with the shorter one at a distance D which may be found from the equation:

$$l\,g\,n\,\frac{2\,L}{d_{max}} - \alpha\cot\alpha = l\,g\,n\,\frac{2\,L}{D} - 1$$

from which it follows that $D = d_{max}\,e^{\alpha\cot\alpha - 1}$

Constant Potential Series Lighting

BY CHAS. P. STEINMETZ
Chief Cons. Engr., General Electric Co.; Prof. Electrophysics, Union College, Schenectady, N. Y.

UNTIL recent years, street lighting in the United States has been almost exclusively by the high-voltage constant-current series system, either direct current or alternating current, and low-voltage constant-potential multiple systems have been used to a very limited extent only. This was for two reasons, one social-political, the other electrical.

To the democratic character of the country, only such form of lighting appeared suitable, as was applicable alike to the scattered suburbs and to the more densely populated center of the city. Thus high voltage had to be used, either a series system, or alternating current with individual transformers. The latter was excluded at first by the absence of a satisfactory alternating-current arc lamp and by the high cost and low efficiency of the small individual transformers. Thus American street lighting developed on the high-voltage series system, and much later only, with the gradual growth of civic pride of the city population, special lighting features were developed such as "White Way Lighting." The alternating-current arc lamp largely replaced the direct-current arc lamp; the small transformers became more efficient and less expensive; but still more efficient and economical was the constant-current transformers operating a whole circuit of alternating arc lamps, so that the conditions which led to the use of the high-voltage series system did not materially change.

The other reason was the electrical characteristic of the arc, which was the only illuminant of sufficient intensity and efficiency for street lighting. The arc is unsteady on constant potential, and requires a constant current or at least a circuit in which the voltage drops greatly with the increase of current. Thus, to operate an arc lamp on constant-voltage supply, a large series resistance or reactance is necessary, which makes it inefficient and, with alternating current, greatly lowers the power factor, and even then, the light is not as steady as when operating on a constant-current circuit.

As seen, of these two conditions, the first one requires high voltage, whether constant potential or constant

Presented at the Chicago Meeting of the A. I. E. E., January 9, 1920.

current; the second one required constant current, which economically means series connection and high voltage. The first one still applies with practically the same force as before, but the second one has entirely changed, and thus makes a reconsideration and revision of our views on street lighting desirable.

With the exception of the luminous arc, which by its high efficiency and superior quality of light—perfect whiteness—holds its own, especially in high intensity and decorative lighting, such as "white way lighting," exposition lighting, etc., the arc lamp has practically disappeared from street lighting, and the gas-filled mazda lamp taken its place. With the disappearance of the arc lamp however, disappeared the necessity of the constant-current circuit. As an incandescent lamp, the gas-filled mazda lamp is a dead resistance, equally stable on constant potential as on constant current, and while the necessity of using high voltage still remains—especially in American cities, which as a rule cover a far larger territory with their street-lighting districts, than European cities of the same population—the need of converting from constant potential to constant current has ceased, and the high-voltage constant-potential street-lighting systems with gas-filled mazda lamps, thus have become possible and are increasing in frequency, either as high-voltage constant-potential series systems, or as high-voltage alternating-current multiple systems with individual transformers.

Unlike the carbon-filament incandescent lamp of old, which has a negative temperature coefficient of resistance, the metal-filament mazda lamp has a positive temperature coefficient, that is with a change of circuit conditions, in the mazda lamp the voltage varies more than the current, while in the carbon-filament lamp the current varied more than the voltage. Therefore, in a constant-potential circuit, the mazda lamp,—other things being equal—will have a better life than in a constant-current circuit having the same percentage fluctuation of current, as the constant-potential circuit has fluctuations of voltage, while the reverse was the case with the old carbon-filament lamp. Constant potential thus is somewhat preferable for the mazda lamp, that is to give the same life of the mazda lamp, the regulation of the constant-current system must be closer than that of the constant-potential system.

The regulation of the available constant-current systems, such as giving by the moving-coil constant-current transformer, reactor or similar devices, is amply close for the successful operation of mazda lamps. It is true that the incandescent lamp is much more sensitive to current variations than the arc lamp was, and while arc lamps are not affected by momentary current variations of 50 to 100 per cent, such as may occur in case of a surging of the circuit due to instability of the arc lamps, swinging grounds, etc., such current variations may be disastrous to the incandescent lamp.

However, in the constant-current mazda lamp circuit if reasonable care is taken of the insulation, the danger of surging hardly exists, and it is only where mazda lamps are operated in series with arc lamps, and the circuit is overloaded and the arc lamps allowed to get out of proper adjustment, that an impairment of the life of the mazda lamp, due to current surges, may occur.

As regards the regulation of constant-potential street-lighting systems, whether high-voltage series, or multiple systems with individual transformers, the problem of regulation of the voltage supply is eliminated by the fact that domestic lighting constitutes a large part of the load of the electric supply system, and the voltage regulation satisfactory for domestic lighting is equally satisfactory for constant-potential—series or multiple—street lighting. That is, constant-potential street lighting is operated from the same supply circuits and in the same manner as domestic lighting is.

Necessary in all series systems is a shunt protective device, that is, a device keeping the circuit closed in case one of the lamps open-circuits. Otherwise either all the lamps would go out or, if the circuit voltage is high enough, arcing occurs and causes more or less damage. The simplest form of shunt protective device is the film cut-out, used very largely in constant-current incandescent lamp circuits. Usually however, one of two other functions are combined with the shunt protective device; to restore automatically operation and to maintain the regulation of the circuit. In incandescent lamp circuits, the former is not necessary, as an open circuiting of the lamp means a burn-out, the lamp then has to be replaced, and when doing so, the film cut-out is renewed. In arc lamps however, the arc not infrequently breaks momentarily, and if then the film cut-out short-circuited the lamp, it would be put out of service. Therefore, in arc circuits, as a part of the arc lamp, a shunt magnet is used closing the circuit through a starting resistance, the latter giving sufficient voltage drop to allow the arc to start again when the electrodes come together.

In constant-potential series circuits, the operation of the film cut-out would reduce the circuit resistance, thereby increase the circuit current and impair the regulation and the life of the lamps. Thus the shunt protective device when operating, must insert a resistance or reactance into the circuit, such as maintains the total circuit impedance unchanged. For this purpose, the same device may be used as in arc lamps, that is, shunt magnet and starting resistance, making the latter equal to the lamp resistance. Such is used in the series operation of a number of arc lamps in direct-current circuits. Or a reactance may be used instead of the resistance, as in the series operation of two flame carbon arc lamps on constant-potential 110-volt circuits.

The objection to this device is the use of moving parts and contacts, and as series incandescent circuits are almost invariably alternating, as shunt protective

device maintaining the circuit regulation, a shunted reactance is used, which remains continuously in circuit, and when the lamp is in normal operation, by-paths only a negligible current, operating below saturation; but when the lamp burns out, the shunt reactance magnetically saturates and thereby drops in reactance to the value required to maintain the regulation. A constant shunt reactance cannot give regulation, since with the lamp burned out, but all other parts of the circuit the same, the total circuit impedance necessarily is higher, thus the circuit current lower, and the reactance in this case thus must decrease, to maintain the same circuit impedance. However, with the lamp burned out, the voltage drop across the shunt reactance is much higher than with the lamp in operation, since in the former case, the reactance voltage combines in approximate quadrature with the remaining circuit voltage.

The requirements of such a regulating shunt reactance thus are: (1) with the lamp in operation, to consume as little current and power as possible. (2) When the lamp opens, to drop by saturation to such a value of reactance as to give the same total circuit impedance as before, and thus maintain the circuit regulation. (3) To maintain the circuit regulation over as wide a range as possible, up to at least 10 to 20 per cent of burned-out lamps, so as to give ample time for renewal. These requirements can be fulfilled by proper design in a very perfect manner.[1]

Such shunt reactance may be, and usually is combined with other features. It may be used as an auto-transformer, so as to operate lamps of different current consumption in the same circuit or to operate a larger number of lamps in one circuit, without excessive voltage, by having the circuit current larger than the lamp current. Or it may be used as a transformer, with sufficient insulation between primary and secondary so as to make the secondary, that is, the lamp, a safe low-voltage circuit, especially when locating the transformer away from the lamp, and grounding it. However, in this case care must be taken in the design of the transformer to guard against dangerous peak voltage. Assuming a 6.6-ampere 300-watt lamp. The normal lamp voltage, and thus transformer secondary voltage, then is 45.5 volts. At open circuit, that is, with the lamp burned out, the secondary voltage then would be of the magnitude of 100 volts effective. However, the voltage wave may be very greatly distorted by saturation, having high voltage peaks—at the moment of magnetic reversal—reaching into dangerous values.

The foremost disadvantage of the constant-potential series system is its lesser flexibility. From a constant-current transformer any number of lamps can be operated, with equally good regulation, from full load down to a fraction of it—though it is economically undesirable to operate a constant-current transformer much below full load, as with decreasing load, the power factor rapidly decreases. In a constant-potential series system, however, the number of lamps is given by the circuit voltage. Thus from a 2300-volt constant-potential supply could be operated $\frac{2300}{45} = 51$. 300-watt 45-volt lamps, neither more nor less. This limitation is overcome by the use of transformer taps and idle regulating reactors. Thus considering a 100-lamp circuit, operated from an ordinary constant-potential transformer with 4500-volt secondary; giving the transformer secondary one 4 per cent and two 8 per cent taps, and using up to 3 idle reactors in series to the circuit, would give a 20 per cent range of load, which probably would be sufficient for most purposes.

A further disadvantage of the constant-potential system is its sensitivity to grounds. If two dead grounds occur in the same circuit, and thereby short-circuit a part of the circuit, the current in the remaining part of the circuit is increased, and if the short-circuited part of the circuit is considerable, all the lamps in the remaining part of the circuit may be burned out. How serious this is, depends on the quality of the circuit. However, with any reasonably well built and operated circuit, the probability of two dead grounds in the same circuit should be so remote as hardly to require much consideration.

On the other hand the great advantage of the constant-potential series system is its high power factor, of 95 to 99 per cent, the better efficiency, and especially, that it requires no station apparatus such as constant-current transformers, but can, and would be operated from a transformer on a pole in the distribution system, just like domestic lighting, and the mass of lines or cables running back to the stations, which are characteristic of the usual constant-current systems, due to the limited power per circuit, thus is eliminated.

In such constant-potential series lighting system, all the street-lighting circuits may be operated from one single feeder or a few feeders, which are connected or disconnected from the station at the proper time. While an advantage over the use of a separate feeder from the station for each street-lighting circuit, this is not as simple and convenient as connecting the constant-potential transformers on the poles in the street-lighting districts, which operate the street lighting, to the domestic-lighting feeders in their respective territory. This latter however requires some means of connecting and disconnecting the street-lighting transformers at the proper time of starting or stopping the street lights, since the domestic-lighting feeders are continuously alive.

Such may be done by manual operation of the switches, though such is rarely satisfactory.

Or it may be done by cascade operation, that is,

[1] Regarding the mathematics hereof, see "Theory and Calculations of Electric Circuits." Chapter XV.

having the street-lighting circuits overlap, and each start the next one, the first being started from the station. This may introduce some complications and limitations of the location of the transformers, and has the disadvantage that, if one switch fails, all the circuits beyond it are out of service.

Or time switches may be used, that is, switches operated by a clock located on the pole at the transformer. Such clocks however, exposed to weather, are not always as reliable as desirable.

Or a pilot circuit may be used, that is, a low-voltage direct-current circuit carried to all the switches. This means an additional circuit.

Another method, which in many cases is very promising, is the use of the phantom switch, that is, a switch operated with direct current by a polarized relay, so that one direction of the direct current closes it, the opposite direction opens it, with the direct current sent to the switch over a phantom circuit, such as are extensively used in telephony. That is, a direct current is sent through a balanced reactance in the station, into the neutral of the alternating-current distribution system, and at the switch passes from the alternating neutral through another balanced reactance to the relay which operates the switch. Such arrangement permits electrical long-distance operation without any additional circuit. It is not applicable in circuits with grounded neutral. However, in primary distribution circuits a grounded neutral is hardly ever used.

Comparing then the three types of high-voltage street-lighting systems; the constant-current series system, the constant-potential series system, and the constant-potential multiple system:

	I Constant-current series system	II Constant-potential series system	III Constant-potential multiple system
(1) Type of lamp.	Arc lamp or incandescent lamp.	Incandescent lamps only.	Incandescent lamps only.
(2) Station apparatus.	Constant-current transformer or reactor, etc.	No station apparatus.	No station apparatus.
(3) Number of station circuits.	A separate circuit for every lighting circuit.	No special circuits from station.	No special circuits from station.
(4) Number of wires per circuit.	Single-wire circuit.	Single-wire circuit.	Two-wire circuit.
(5) Accessories at lamp.	Film cut-out, or auto-transformer or series transformer.	Auto - transformer or series transformer.	Constant-potential transformer.
(6) Size of circuits.	Limited number of lamps per circuit.	Limited number of lamps per circuit.	Unlimited number of lamps per circuit.
(7) Flexibility.	Great flexibility in number of lamps.	Lesser flexibility.	Great flexibility in number of lamps.
(8) Power factor.	80 to 85 per cent with incandescent lamps. 70 to 75 per cent with arc lamps.	95 to 99 per cent.	Practically unity.
(9) Safety.	High voltage at lamp except when using transformer.	High voltage at lamp except when using transformer.	Low voltage at lamp.

Notes

(2) For I, constant-current pole transformers have been designed, without moving parts, and are in successful use to some extent, especially for smaller circuits; but usually are either lower in power factor or inferior in regulation.

Theoretically, II may be operated directly from the primary distribution feeders, but usually it will be preferable to interpose a constant-potential transformers on a pole in the lighting district, so as to reduce the trouble from grounds.

(3) In II or III, provision must however be made for starting and stopping the circuit, as discussed in the preceding.

(5) The film cut-out, as the simplest shunt protective device, is applicable only in I.

To secure low voltages at the lamp, so as to make it safe even when the circuit is alive, requires transformers in I as well as II. However, these transformers are series transformers, that is, with a moderate number of primary turns, while in III, the transformer has to step down from the total circuit voltage to the lamp voltage, requiring many turns of fine wire in the primary, and thus is more expensive to build and insulate.

In III, several lamps may be operated from the same transformer, if near together, but this then means a two-wire secondary circuit in addition to the primary circuit. The same could also be done in I or II.

(6) Both series circuits are limited in the number of lamps per circuit, but this limitation, while serious in a constant-current circuit which has to go back to the station, is of no moment in the constant-potential circuit, as the latter does not need to run back to the station but is fed from the transformer on the pole in the lighting district, and such transformer is of sufficient size to be efficient and economical.

The Alternating-Current Commutator Motor

BY B. G. LAMME

Chief Engineer, Westinghouse Elec. and Mfg. Co., East Pittsburgh, Pa.

The alternating-current commutator motor in its various forms has been developed principally for the purpose of obtaining adjustable or variable speeds, the usual induction type motor, both in the single-phase and polyphase forms, being inherently constant speed. In general, control of speed with the alternating-current induction motor implies variable or adjustable frequency in some form, and this, in turn, involves a commutator of some type. In consequence, the problem of commutating alternating current usually goes hand in hand with that of speed control.

The simplest method, according to the author, for viewing both the a-c. and the d-c. commutating problems, is to consider primarily the actual e.m.fs. short-circuited by the brushes, and the resistance in the short-circuited paths,—or in other words, the problem of commutation is largely one of the permissible amount of short-circuited current. In the d-c. machine the e.m.f. short-circuited by the brushes is that generated by rotation of the short-circuited armature coils in the armature and external field fluxes. In the same way, in the a-c. commutator motor, there is an e.m.f. due to the armature flux or field, as in the d-c. machine, and in addition, there are other e.m.fs. due to the primary or field fluxes. These latter may be classified as primary rotational and transformer e.m.fs. One limitation in the design of a-c. commutator motors, in general, is that these rotational and transformer e.m.fs. are often larger in degree than the e.m.f. due to the armature flux. However, the author contends that the commutation problem in a-c. motors is the same as for d. c. when all e.m.fs. are taken into account.

The major part of the paper covers the consideration of the different e.m.fs. which should be taken into account in the various types of a-c. commutator motors, and it is shown in a general way that the e.m.fs. involved in speed control also appear in the commutation problem. In the latter part of the paper certain general conditions of commutation and brush operation are treated and some figures are given for comparison of a-c. and d-c. commutating limits.

THE alternating-current commutator motor in some form is doubtless the earliest of all alternating-current motors. Probably everyone of the old-timers who dabbled in alternating currents tried his hand, sooner or later, at this type of machine. Some even went so far as to put such motors on the market. Series-wound, shunt-wound, repulsion types, induction types, as they were formerly named, all had their trial, either experimentally or commercially, and all the early motors withdrew for one common reason; namely, sparking at the commutator. It must be kept in mind that all the earlier frequencies were quite high and it was recognized, early in the game, that this was a most serious handicap to successful commutation. One principal reason why the Niagara Falls Power Commission in 1892 chose 2000 alternations per minute (16 $^2/_3$ cycles per second) as its preferred frequency, was that commutator-type a-c. motors would thus be feasible for general power work.

In consequence of the commutation difficulties with all the early a-c. commutator motors, and their consequent withdrawal from the commercial field, the belief became most firmly established that alternating currents, in general, could not be commutated successfully and that it was hopeless to attempt further work on the problem.

This fallacy was the direct outcome of lack of knowledge of the general problem of commutation itself. The alternating current simply introduced additional conditions, all of which made the whole subject more complex and difficult to understand. In fact, in this early period, in most cases, the methods of treating the direct-current commutation problem were more or less incomprehensible and there was little or no physical conception of what was really taking place.

With clearer and better conceptions of the commutation problem, it began to be seen, by a few, that alternating-current commutation was quite closely related to that of direct-current; in fact, if all the conditions were included, it was evidently the same problem except in degree.

However, in one vital feature, the commutation in a-c. machines has been assumed to be fundamentally different from the d-c. In the former, the condition in many cases is largely that of short-circuiting part of the armature winding, by the brushes, under a magnetic field, or when enclosing an alternating magnetic flux. Superficially, this problem appears to be quite different from that of simply reversing the current in those armature turns lying midway between poles, as in the usual d-c. machines. This short-circuiting under a magnetic field (or enclosing an alternating flux) was supposed to introduce new and most intricate phenomena, and, apparently, the action was such that good, or even passable, commutation was not even theoretically possible.

As the theories and practises in d-c. commutation developed, new ideas began to grow and new viewpoints were obtained, which had a direct bearing on the corresponding a-c. problem. It was perceived, perhaps dimly at first, that the d-c. problem could be considered simply as a case of the brushes short-circuiting part of the armature winding in a magnetic field, such field being set up by the armature winding as a whole, or by a combination of armature and field fluxes. From such a viewpoint the problems of a-c. and d-c. commutation began to approach each other, and it was perceived that it was largely a matter of the values of the e. m. f. short-circuited, rather than the nature of the current itself.

Others may have anticipated the writer in this method of looking at the commutation problem, but

Paper to be presented before the Schenectady Section of the A. I. E. E., April 2, 1920.

possibly he was the first to go fully into the analysis of this method and to show its equivalence to former methods.[1] He found that this way of viewing the problem was of very great help in the consideration of a-c. commutating machines, both polyphase and single-phase. It put the short-circuiting and commutation problems on a comprehensible basis and at once eliminated from the treatment a large number of intermediate phenomena.

To express this method in its simplest form,—if a given e. m. f. at the commutator is short-circuited, with a given brush, similar commutating conditions are obtained, whether the current is alternating or direct. But *all* the e. m. fs. must be taken into account, and here has been the principal source of trouble, both in a-c. and d-c., but more in the former than in the latter.

In accordance with this method of treating the problem, the function of commutating poles, or their equivalent, is simply to reduce the short-circuited e. m. f. under the brush to a value within the resistance limits of the brush, as fixed principally by the brush contact and by any additional resistance in the winding which may be inserted for commutation. With the d-c. machine, this has been quite easy, as both the e. m. fs., due to the armature flux and due to the commutating pole, are proportional to the speed, and therefore, if properly set for one speed, the conditions hold for all speeds. But in the a-c. motor some components of the e. m. f. short-circuited by the brush are not a function of the speed, while others are, and thus the problem of a correct commutating field for a wide range of speed becomes a very complex one. The difficulty is inherently one of design, rather than one of theory or principle.

Narrowed down to its simplest form, in the d-c. machine, the commutation is dependent upon the e. m. f. short-circuited by the brush, and the permissible short circuit or local current. The permissible work current enters directly as one of the elements which determines the short-circuited e. m. f. The amount of short-circuit current permissible is dependent largely upon the characteristics of the brush and brush contacts. The amount of short-circuit current which can flow is dependent upon the e.m. f. short-circuited, and the conditions of the short-circuited path. Due to the characteristics of commercial carbon brushes, there are fairly definite limits to the e. m. f., which can be short-circuited while keeping the short-circuit current within the limitations of the brush itself as fixed by burning, disintegration, etc.[2]

In the a-c. machine quite similar limits hold, except that the short-circuited e. m. f. is partly, or in most cases largely, due to fluxes other than those resulting from the armature m. m. f. as in d-c. machines. In consequence, on the d-c. conditions are superposed additional ones, which often are more difficult than those corresponding to the d-c. However, the whole problem turns on the total short-circuited e. m. f. and the means for limiting the circulating or local current.

So much for commutation. Now as to the reasons for the use of commutator motors, when induction motors, both polyphase and single-phase, have been available. It has been well known, almost since the induction motor first appeared, that this type of machine has inherently constant speed characteristics. With the growth of the art and increase in the field for electric motors, there has come a demand for variable and adjustable speed alternating-current motors. The true induction motor cannot in itself give the variable speed characteristics of the series d-c. motor, nor the adjustable speed characteristics of the shunt machine. True, variations in speed with the polyphase induction motor are obtainable by means of resistance in the secondary circuit, but such speed regulation is directly comparable with the use of armature resistance in d-c. shunt motors and this characteristic is not a desirable one except for certain very limited uses.

The problem of true speed control in the induction motor is complicated by the fact that with change in speed, both the secondary voltage and the secondary frequency are directly related to the speed changes. It has been known for many years that, by the addition of suitable voltages in the secondary circuit of the ordinary polyphase induction motor, the speed could be controlled over any desired range, without rheostatic loss, but for each change of speed the regulating voltage supplied to the secondary winding requires a different frequency, and the difficulty in the past (as well as at present) has been to obtain the required special frequency for each speed. It is true that a very limited number of speed changes is possible by means of pole changing and by cascade connection of motors, but these give no true flexibility in speed adjustment. Up to the present, the only really flexible means for obtaining variable frequency for such motors has been through some form of a-c. commutating device, such as a multi-bar commutator connected to the secondary or the primary winding; or a commutator-type frequency changer, a synchronous converter, or a polyphase commutator-type motor, structurally independent, but connected to the primary or secondary circuits of the induction motor. It may be noted that the synchronous converter, transforming from alternating to direct current, is here included among the frequency-changer devices. This should be considered as a frequency changer when used in this manner, converting from direct current (zero frequency) to any a-c. frequency depending upon the adjustments. This implies direct-current circuits in addition to the alternating-current supply circuits. However, many of the

1. *A Theory of Commutation and its Application to Interpole Machines*, TRANS., A. I. E. E., 1912.

2. See *Physical Limitations in D-C. Machines*—TRANS., A. I. E. E., Sept., 1915.

other devices proposed imply transformation from the primary or supply frequency to some other frequency or range of frequencies, or vice versa. The commutator thus enters as a frequency-changing, rather than a current-rectifying device.

The Polyphase Commutator Type Induction Motor

Although the polyphase motor without commutator is a well understood device, yet there are various ways of treating its characteristics with regard to speed variations, etc. Some of these methods serve better for illustration than others. The following treatment, which has been used extensively by Eichberg, McAllister and others, probably gives the best visual conception of what takes place in such machines, in regard to the component voltages upon which commutation and speed regulation depend. The writer has accordingly adopted this for purposes of easy illustration, in connection with the several types of apparatus which are considered.

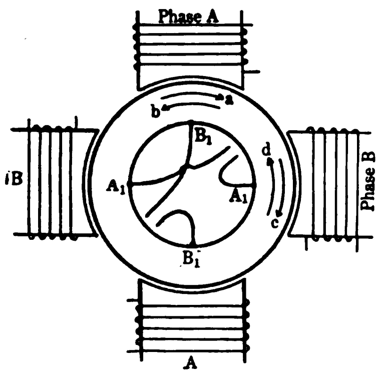

Fig. 1

Assume as the first and simplest case, a two-phase induction motor, in which the primary is illustrated as a two-pole construction with two sets of poles at right angles to each other, as shown in Fig. 1, and with a secondary of a ring type with four taps at A_1A_1 and B_1B_1 for two-phase connection. The e. m. f. relations in the secondary winding may be explained as follows:

Considering the rotational e. m. fs. first, the alternating flux from pole or phase A through the secondary will generate an e. m. f. a, as indicated in Fig. 1. Also the alternating flux from pole or phase B will generate in the winding a rotational e. m. f. c, as shown. These e. m. fs. are dependent upon the primary flux and the speed of rotation and are independent of the primary frequency. Due to the fact that the flux and poles A and B are at 90 deg. relation to each other, these two rotational e. m. fs. a and c are at right angles to each other.

Let us now consider the transformer action of the primary fluxes acting on the secondary. The rotor winding along the axis of pole or phase A will generate an e. m. f. d 90 deg. out of phase with the flux of phase A. This is indicated in Fig. 1. Also the winding along axis B will generate a transformer e. m. f. b. In the winding under pole A, therefore, there will be two component e. m. fs. a and b, which are in opposition to each other, a being in phase with the flux in phase A, and b being 90 deg. out of phase with the flux B, which in turn is 90 deg. out of phase with flux A. Thus a and b are 180 deg. part, neglecting minor effects. In the same way, under pole B, e. m. fs. c and d are approximately 180 deg. apart.

Obviously, the rotational e. m. fs. a and c are dependent upon the speed of the secondary and therefore vary from zero, at standstill, to values equal to b and d when the rotational frequency (poles times revolutions) is equal to the line frequency; for with equal fluxes, equal frequencies, and other conditions, e. m. fs. set up by rotation are equal to the e. m. fs. set up by so-called transformer action. Therefore, at synchronous speed of the secondary, the rotational and transformer e. m. fs. in the secondary windings practically balance each other, in a well-designed machine. Obviously, in the external secondary circuits the e. m. fs. will vary from maximum at standstill to zero at synchronism, considered simply from the standpoint of the component e. m. fs. a, b, c and d, as shown in Fig. 1.

It is evident that the rotational e. m. fs. a and c correspond to the counter e. m. fs. in an ordinary motor, while the transformer e. m. fs., b and d, correspond to the impressed e. m. fs. Thus by comparison, the rotational or counter e. m. fs., a and c are zero at standstill and rise in value until they are practically equal to the impressed e. m. f., as in ordinary types of electric motors.

Now as to the frequency of such secondary circuits,—at standstill obviously this must be the same as the primary or supply frequency; and as the secondary winding is rotated in the direction of the primary rotating magnetic field, the secondary frequency will decrease, reaching zero at synchronism with the primary field. Thus the secondary voltage and frequency both are dependent upon the speed of rotation. This, of course, is all an old story, but is brought in here simply as part of the problem of commutation and speed variation.

If the secondary circuits are connected to the secondary windings by means of permanent connections, then obviously, the points of connection will rotate with the secondary core. If, however, the secondary winding is provided with a commutator and the secondary circuits are connected to the secondary winding by means of brushes on such commutator, then the connection of the secondary circuits to the secondary winding becomes a variable or movable one, depending upon the motion of the brushes relative to the commutator. If the brushes are in a fixed position on the commutator, as shown in Fig. 2, then the secondary connections are fixed in space, so to speak, instead of rotating with the secondary winding. In such an

arrangement, the frequency of the external secondary circuits at any speed is the same as with the usual induction motor at standstill. In other words, it is always the same as that of the supply circuit, although the e. m. fs. in the secondary circuits will vary with the speed, as in the ordinary induction motor. Consequently, this arrangement differs from the usual induction motor, in having full line frequency, with varying voltage, in the external secondary circuits, whereas the usual induction motor has varying frequency and varying voltage in such circuits. The interesting feature in this arrangement is that we now can supply e. m. fs., at line frequency, to the secondary circuits for speed control. From an inspection of Fig. 2, it is obvious that for stable conditions, e. m. fs. *a* and *b* must balance if no other conditions are introduced; that is the motor will tend to run up to synchronous speed. However, if external e. m. fs. respectively in phase with *a* and *c* are added, then these e. m. fs., plus *a* and *c* can balance *b* and *d* at some other than synchronous speed, and thus stability is obtained at other than synchronous conditions. It is thus evident that,

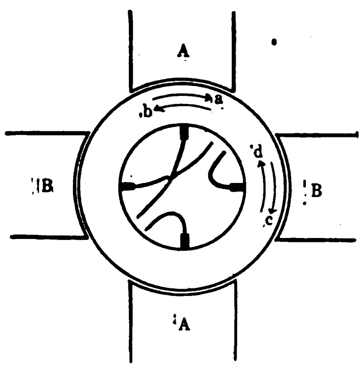

Fig. 2

by means of the commutator, we are able to introduce into the secondary circuits suitable e. m. fs. at line frequency to accomplish this result, and this is one of the methods which has been used in the past for speed control of polyphase motors. The A. E. G. Co., of Berlin, has built such motors, in which the supply circuits for the secondary voltage regulation are obtained from special windings on the primary, with a number of taps to give different voltages. In other arrangements transformers have been used for converting from the line to the desired secondary voltages, with a number of taps for varying such voltages.

The above covers broadly this general method of speed control. Let us look now into the problem of commutation in such machines, as determined by the e. m. fs. short-circuited by the brushes. In the first place, at standstill the volts per conductor or turn are practically the same as in the primary winding, and the e. m. f. spanned by the brush is dependent upon the volts per turn and the number of turns short-circuited. In the second place, as the secondary speeds up, its resultant volts per turn decrease directly as the speed increases, for the rotational e. m. f. per turn is rising and more nearly approaches in value the opposing transformer e. m. f. per turn. The e. m. f. short-circuited by the brush decreases accordingly, reaching practically zero value at synchronous speed in a well-designed machine, and again rising in value above synchronism. This is the resultant e. m. f. due to the primary flux. If this resultant were the only e. m. f. to be considered, the problem would be fairly simple in its explanation. However, there are other magnetic fluxes due to the rotor magnetomotive forces, as in d-c. machines, which also set up e. m. fs. and the inclusion of these complicates the explanation. These latter, however, are usually small compared with the resultant short-circuited e. m. f. due to the primary field, and in most cases are largely masked by the latter, except near synchronism. Ordinarily the conditions which tend to give a low short-circuited e. m. f., due to the primary field, also tend to reduce these lesser e. m. fs., so that in general one need consider only the larger e. m. f. due to the primary field. By reducing this to a value within the limits of resistance commutation, and proportioning the armature so that it would be very good for commutating a corresponding direct current, one usually need consider nothing else, for practical purposes. Obviously, in the motor just described the commutating conditions will be easiest near synchronism and will become increasingly difficult with departure from synchronous speed. In practise, the permissible limit of short-circuited volts for operative commutation may be reached anywhere between synchronism and standstill, depending upon the design.

From the preceding description, it is evident, in the general problem of speed control, that we must take into consideration the frequency of the current handled by the circuits connected to the brushes on the commutator. While this may have little bearing on the general question of commutation, it is one of the important features in the general scheme of speed variation or control of the induction motor. Therefore where there are two (or more) sets of circuits connected to one or both motor windings, it may be advisable at this point to show in a simple way the relation of the frequencies in these circuits. Such circuits may be connected to the windings, either by permanent taps or by variable taps through the medium of brushes on one or more commutators. One set of these circuits may always be considered as a primary or supply system and the others as secondary circuits, whether they are on the primary or the secondary core. A simple rule can be given for the relation of these frequencies in polyphase motors,—namely, *the frequency of any external secondary circuit relative to the primary or supply circuit is determined by the relative angular movement of its points of contact with respect to those of the primary circuit.* If these contacts have a fixed angular relation to each other, then the frequency of the secondary circuits is always the same as that of the primary circuits. If

these are moving with respect to each other, the frequency of the secondary circuits will vary from that of the primary according to the relative movements.

For example, in the usual induction motor, with stationary primary and wound secondary with collector rings, at standstill the stator and rotor taps on the windings have a fixed relation to each other and the frequency of the secondary current is therefore the same as that of the primary. As the secondary core and windings increase in speed, the rotor taps move with respect to the primary and the frequency of the secondary external circuits is thus varied.

In the same way, the motor with a commutator on the secondary and with fixed brushes, will, according to the above rule, give full primary frequency on the secondary external circuits at all speeds, simply because the secondary taps, or points of contact, hold a fixed relation to the primary taps. Any rotation of the secondary brushes will give a varying frequency in the secondary external circuits, depending upon the speed of rotation of the brushes.

There are various modifications of the polyphase commutator-type motor, several of which involve special commutating conditions, and therefore should be described briefly. One of these is known as the Schrage motor. This is a polyphase induction motor with a rotating primary with polyphase taps and collector rings and also with a commutator and polyphase brushes. In its simplest form the commutator and the collector ring taps are connected to a common winding of the closed coil direct-current type. In the more usual form there is a second low voltage winding on the rotor core which is connected to the commutator, the primary winding proper being of higher voltage and not connected to the commutator in any way. By this latter arrangement, the primary supply e. m. f. and the low voltage required on the commutating winding become independent of each other and each can be proportioned for its own best requirements. This may be illustrated, in its arrangement of circuits by Fig. 3. Here only a single primary winding is shown, for simplicity, with both the collector rings and the commutator connected to it. $A\ A\ A$ represent three sets of fixed brushes, while $B\ B\ B$ represent movable ones.

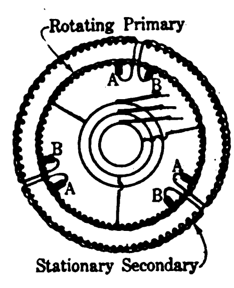

Fig. 3

According to the foregoing method of determining the frequency etc., between brushes A and B, there is a fixed e. m. f., but a frequency depending upon the speed of rotation. Connecting the circuit from $A\ B$ to a phase group on the stator core, the speed will balance at such point that the e. m. f. and frequency of the brushes will equal the stator e. m. f. and frequency. By rocking B to some new position, a different voltage is obtained between brushes A and B and thus a new speed is required for balancing the e. m. fs. and frequencies.

In this arrangement the commutating brushes are fixed in position while the winding, commutator and primary supply taps revolve. Here the primary field or flux travels at a definite speed with respect to the rotor core and windings, the primary current being supplied through the collector-rings and taps to the winding. Just as in a stationary primary, the primary counter e. m. f. and the effective e. m. f. per turn, are constant, as they depend upon the rotation of the primary field or flux with respect to the primary core and windings. Therefore the short-circuited e. m. f. under the brushes on the primary winding is constant and corresponds to that portion of the primary e. m. f. spanned by the brushes. Herein lies one reason for the use of the double primary winding. With a very high applied e. m. f., the number of primary turns would be high and the turns per coil or per commutator bar would be unduly large unless an enormous number of commutator bars is used; but the addition of the low voltage winding allows this element to be proportioned to suit the short-circuited conditions and the number of commutator bars, independently of the primary winding proper.

This arrangement short-circuits the full value of primary e. m. f. per turn at all speeds, but the brushes do not handle current of the primary frequency, but of a frequency depending upon the speed, for the primary taps and the brushes on the commutator are moving with respect to each other, except at standstill. The frequency delivered at the commutator therefore varies from full-line frequency at standstill to zero frequency at synchronous speed. However, the voltage delivered from the winding to the brushes is practically constant at all speeds. The result therefore is just the opposite of that described in connection with the polyphase motor with a commutator on its secondary, for in that case the frequnecy delivered at the commutator was constant and the voltage varied with the speed, whereas in this latter case, the frequency varies with the speed and the voltage is constant with a given brush setting. As the frequency and voltage of the stator winding of this motor both vary with the speed, as in the usual induction motor, it is thus possible in this motor to obtain speed regulation by connecting the circuits from the primary commutator brushes directly to the secondary winding, provided voltage adjustment is obtainable. This, of course, can be accomplished by means of transformers and in various other ways, but in the Schrage motor, as built, this is obtained by the two sets of brushes on the commutator, as shown in Fig. 3, which can be displaced with respect to each other, so that the voltage between them can thus be varied up or down by suitable setting of the brush arms. In this way the armature winding and the commutator are used as the equivalent of a transformer with variable voltage taps, so that both frequency and voltage are thus under control.

As far as commutation is concerned, this scheme is

at a disadvantage compared with the previously described arrangement with the commutator on the secondary winding in which the short-circuited e. m. f. varies with the slip from synchronism. With this latter scheme, therefore, commutation is to a considerable extent independent of speed, simply because the short-circuit conditions are equally difficult at practically all speeds. If such a machine can be made to operate sufficiently well at any one speed, it should then be suitable for operation over a fairly wide range of speed.

It is apparent from the description of this Schrage motor that the rotor becomes simply a changer of frequency, but not inherently a transformer of voltage. A similar arrangement was devised many years ago by the writer purely as a frequency changer, and it is being used at present in connection with speed control of large induction motors. The rotor of this machine, as shown in Fig. 4, consists of a primary winding on the rotor core connected to both a commutator and a set of collector rings. In operation the core is rotated inside a laminated ring, which may or may not carry any windings. At synchronism with the a-c. supply or primary system, the commutator delivers direct current at a voltage proportional to that of the alternating

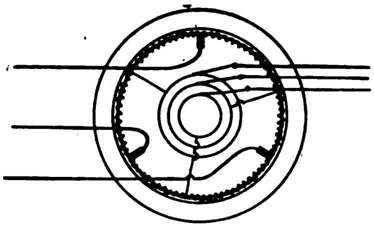

Fig. 4

e. m. f. impressed. With change in speed, either up or down from synchronism, the brushes deliver current at a frequency varying with the slip from synchronous speed, but the e. m. f. delivered is constant with constant supply e. m. f., regardless of the slip. This is therefore a variable-frequency, constant-voltage machine and the conditions of commutation are fixed principally by the primary flux or field, practically regardless of speed. By the use of several sets of brushes, properly spaced on the commutator, polyphase currents are taken from the commutator.

A third form of polyphase commutating motor was proposed in Europe some years ago, in which a stationary primary winding of the closed-coil type is connected to a commutator, and the current is admitted by brushes which are rotatable on this commutator. It is at once evident that this is simply an induction motor primary in which the points of current supply can be rotated around the core. In consequence, the speed of rotation of the primary field, or flux, corresponds to the line frequency, plus or minus the speed of rotation of the brushes. The secondary core and winding, of usual polyphase type, at full speed rotates at practically the speed of the primary field; and accordingly its speed will vary directly with that of the primary supply brushes.

Looking into the conditions of commutation in this type of machine, it is at once noted that, as the brushes short-circuit part of the primary winding which generates the counter e. m. f. of the machine, the short-circuited e. m. f. will be proportional to the counter e. m. f. and therefore will be of practically constant value. Here the conditions and limitations of commutation are fixed almost entirely by the primary e. m. f. short-circuited, and practically no other e. m. f. conditions need be considered. If five volts, for instance, could be taken care of by the brushes, then they would stand an average of five volts on the commutator at any speed within reason. As far as commutation is concerned, this motor is subject to the same limitations as the Schrage motor with a single primary winding.

The above covers briefly the polyphase induction motor with commutator. Polyphase series and shunt types of commutator motors might be considered as next in order, but they are so closely related to various single-phase types, that their treatment, according to the foregoing method of illustration, should properly follow the single-phase. Therefore, they will be taken up later.

Single-Phase Commutator Motors

These may be of various types or forms, such as series, repulsion, doubly-fed and induction types. In these, in general, the commutating conditions are more difficult to analyze and to explain than in the polyphase induction motor, just as the phenomena of single-phase induction motors, in general, are usually more difficult to grasp than those of the polyphase. Also just as the assumption of two component fields of opposite rotation can replace the single-phase field in considering some of the characteristics of single-phase motors, so in commutation of single-phase machines this assumption may be of assistance in some instances, in explaining the actions, although the writer has not used the method in this paper.

Single-phase motors are structurally of two types, namely, of the polar and of the distributed type fields. In practise these are equivalent, but the distributed type, with its overlapping windings and fluxes, introduces such complexity, in any general analysis, that for purposes of illustration, a polar arrangement should be shown. Consequently, in the illustrative diagrams, which are given later in connection with single-phase motors, polar arrangements are given. It might be well, therefore, to show the equivalence of the two arrangements insofar as principles are concerned.

Equivalence of Polar and Distributed Windings. Taking the simplest type of distributed winding,—namely, the *closed-coil, ring type,* other types and arrangements can be developed from it quite easily.

Assuming such a ring-type closed coil, as shown in Fig. 5, then with taps at A and B there will be a maximum m. m. f. at A and B tapering off to zero midway between. Thus there will be magnetic poles with maximum value at A and B and zero at midway points.

The same holds true for a closed coil armature. The maximum m. m. fs. of the armature windings correspond to the points of current connection, as shown in Fig. 6.

Let us consider such an armature in a ring field of this type. Fig. 6 illustrates this. With the brushes

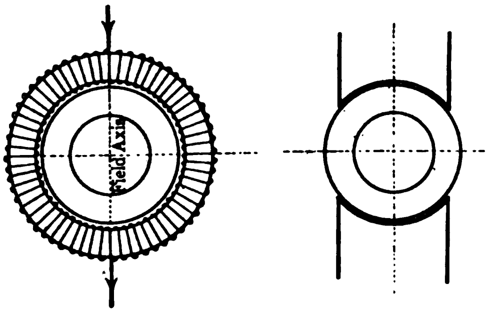

FIG. 5

on the armature at right angles to the field taps, and corresponding to the points of zero field flux, the arrangement is equivalent to the usual d-c. motor with two poles and with the armature brushes on neutral. Here *all* the field winding is magnetizing.

However, let us next shift the armature brushes around to another angle than 90 deg. to the field axis. Assuming a 45 deg. angle, the arrangement is as in Fig. 7. Then all the field winding between A and C, representing double the angle between the armature and field axes, becomes magnetizing or exciting field winding and sets up a magnetic field at right angles to

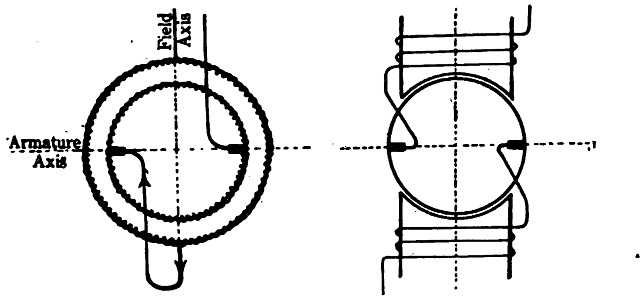

FIG. 6

the armature axis or brushes; while the part of the field winding between B and C represents a m. m. f. acting *parallel to the armature axis*, but in opposite direction to the armature m. m. f. This part of the field winding *thus automatically becomes a compensating winding.*

Taking again a much smaller angle between the field-winding and armature-winding axes, as in Fig. 8, here again the field winding between A and C becomes magnetizing, while that between C and B becomes compensating. Thus by setting the armature brushes at various angles to the field-winding axis, components of the field winding equal to double these angles, become magnetizing, and the remaining parts become compensating. This relation is just as definite, and in fact is the same thing, as using two separate windings for exciting and compensating, connected in series, and with armature brushes at a midway point in the distributed exciting winding. With the two distinct winding arrangements, the relation of exciting to compensating strength can be changed without changing the brush angle, which is not the case with the single

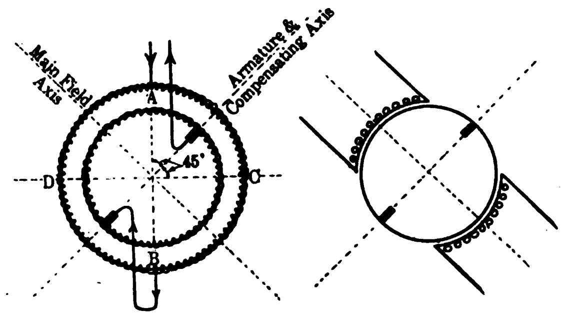

FIG. 7

winding. Or stating the matter in another way, the field strength, and thus the speed, may be changed without shifting the brushes. However, in principle, the arrangements are the same.

The disadvantage in directly representing the polar conditions with distributed windings, in the various single-phase motors illustrated in the following figures, is that the overlapping poles and fluxes are confusing to almost everyone except the designer. In consequence, the writer has shown the fluxes as separate

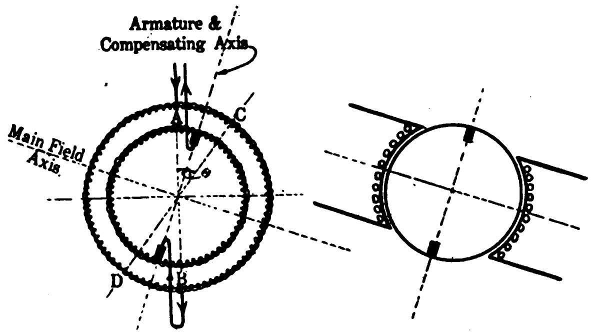

FIG. 8

magnetizing and compensating or transformer components in order to illustrate more easily the principles of operation and of commutation.

Single-Phase Series Motors. Of all the single-phase motors, presumably the straight series type is one of the simplest to explain from the standpoint of commutation, as well as otherwise. This motor is, in effect, just like a d-c. series motor of similar general construction and the performance is much the same. However, it differs from the d-c. series motor in one essential point; namely, there are two e. m. fs. set up in the armature

winding, although not along the same axis, these e. m. fs. being the rotational and the transformer e. m. fs. due to the main field flux. This is illustrated in Fig. 9. The rotational e. m. f. is along the axis of the brushes, while the transformer e. m. f. is along the field axis, and at right angles to the rotational, and therefore has no direct influence on the latter. However, the brushes short-circuit part of the transformer e. m. f., as will be considered further.

In its commutation the series motor embodies the equivalent of the usual d-c. problems, plus the additional one due to the transformer e. m. f. in the armature windings. Thus there are two short-circuited e. m. fs. to take into account, one being due to rotation in the armature field or flux, and the other to transformer action. These are 90 deg. out of phase with each other. This, together with the fact that one of these e. m. fs. is dependent upon armature speed while the other is independent of it, makes any commutating pole problem quite difficult, for this type of motor is used principally where speed variation over a wide range is one of the requisites. However, it is the transformer component which is the great handicap in

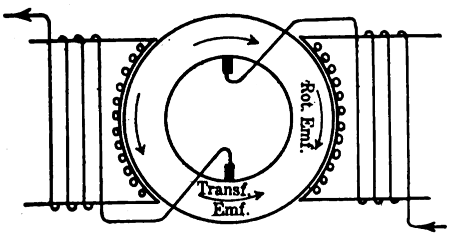

Fig. 9

a-c. commutation in general, for it is not possible to counterbalance completely such an e. m. f. under all conditions, by any corrective e. m. f. depending upon rotation, as is done in d-c. machines; for at zero speed this transformer e. m. f. still exists at full value, whereas no rotational e. m. f. is possible under this condition. Therefore, in this, as in all a-c. commutator motors, the standstill condition represents a limit where compensation, or the commutating pole in any form, is ineffective. Under this condition, however, only the transformer e. m. f. is short-circuited by the brushes, all rotational e. m. fs. being absent.

As this transformer e. m. f. in the short-circuited coils is proportional to the main field flux, it might be assumed that there could be a considerable gain by reducing the field flux during starting and at lower speeds. However, this cannot be carried very far, for the torque of the motor also depends upon the main field flux, and thus any reduction in this flux means correspondingly increased armature current,—so that the reduction in the short-circuit or local current is accompanied by an increase in the work current.

In his early work on single-phase commutator motors, the writer recognized the condition of a limiting e. m. f. which could be short-circuited successfully by the brushes, and his early experimental designs were all along lines of obtaining a sufficiently low transformer e. m. f. Low frequency, of course, was one of the recognized factors in accomplishing this. Mechanical limitations in the number of commutator bars, width of brush, etc., and the electrical limits of volts per bar, at once dictated that the counter e. m. f. of such a machine must be relatively low. There was much criticism at that time regarding the adoption of such low voltage for a-c. series motors,—about half that of d-c. railway practise,—but it may be noted that no one in the succeeding twenty years has been able to increase greatly over the armature voltages which were first used, with motors of corresponding speed and capacity. Here appeared to be a fundamental limitation, partly of a mechanical and partly of an electrical nature.

In the study of the short-circuited transformer e. m. f., it appeared at that time that somewhat higher short-circuited e. m. f.s. under the brush would be allowable, by including a considerable amount of resistance in the short-circuited paths, in order to reduce the short-circuit current. In consequence, the use of resistance, or preventive, leads, between the commutator and windings, was proposed and tried with the result that materially higher short-circuited e. m. fs. proved to be practicable, and thus correspondingly higher main flux densities were permissible. The writer has never carried this construction to its extreme limits, as no very good opportunity offered itself. The use of resistance leads for such purpose was not new or novel, but the writer believes the results he obtained were much more satisfactory and conclusive than in former trials, largely because the leads were applied with due regard to the electrical limitations of the short-circuited e. m. f. and the values of local and work current, etc.

In the early days the writer also gave serious consideration to the problem of commutating poles on series a-c., single-phase, motors and even carried this to the extent of trying it out on a 300-h.p. motor. This was not for the purpose of eliminating the resistance leads, as he did not believe at that time that this was practicable, on account of starting conditions, but it was for reducing the short-circuited e. m. f. under the brushes, while in rotation, by introducing a counter-acting e. m. f. Unfortunately, these tests were carried out entirely with series excited commutating poles. There was a very considerable improvement at high speeds, but at moderately low speeds no improvement was apparent. Of course, it was recognized, even at that time, that the transformer e. m. f. under the brush was out of phase with the armature current and it was doubtless recognized that the phase relation of the commutating pole flux was not just what it should be. However, the general results, as tested, held so little promise, except at quite high speeds, that it was felt that it was not worth while to follow this matter up

further. At that time the proportioning of commutating poles and commutating-pole windings was not very well understood, even on direct machines, so it is not surprising that anyone should be misled on the a-c. machine.

More recent work on commutating poles in such motors has shown that properly proportioned poles and windings with suitable phase shift of the current will materially improve the commutation over a relatively wide range of speed beginning at fairly low speeds. Experience also shows that, by such means, series motors without preventive leads can be made to give results comparable with motors with such leads, but without commutating poles. Very considerable development has been carried on recently along such lines. These good results are due, largely, to better knowledge of the most desirable proportions, etc. This will be treated more fully, later.

No mention has been made of compensating windings on series motors. Such windings were developed very early, but principally for the purpose of improving the power factor by neutralizing the armature m. m. f. Apparently this did effect some slight improvement in the commutation, but it was possibly a mere question of opinion. Both series-connected and shunt-connected compensating windings were tried, the latter operating fairly well but seemingly representing no physical improvement over the series arrangement. Over-compensation with the winding series connected, appeared to represent little gain. In fact, the compensating winding short-circuited on itself seemed to be just about as effective as any other arrangement, in most of the tests.

Repulsion Motor. Another early development was the so-called repulsion motor, now known as a transformer type. We will retain the older term, as it is better known. At first, this was believed to be a distinct type of single-phase motor, although its characteristics were recognized as being very similar to those of the series machine. In an Institute discussion of repulsion motors, in January, 1904, the writer showed that this type of motor was simply a series type, in which the current in the armature was generated by transformer action, instead of being fed in directly at the brushes. In other words, it is a transformer type series motor. Possibly there was no novelty in this form of treatment, but it enabled one to analyze this type of motor from the series standpoint. This method of treatment also allows the commutation problem to be considered in a fairly simple manner.

A brief review of this method may be given here, not simply for the purpose of showing the relation of the repulsion to the series motor, but to bring out some of the commutating conditions not included in the former discussion, and also to show the close resemblance to some of the conditions in the polyphase induction motor, as described and illustrated in connection with Figs. 1 and 2.

Assume first a series motor with its armature fed from the secondary of a transformer, the primary of which is in series with the motor field. Also assume for simplicity a 1 : 1 ratio of transformation. Fig. 10 illustrates this arrangement.

With a given field flux, the armature winding will generate along the brush axis a rotational e. m. f. directly proportional to the speed, and counter to that of the secondary of the transformer, to which its brushes are connected. This, therefore, fixes the value of the secondary e. m. f. of the transformer and, therefore, its primary e. m. f. Accordingly, with a 1 : 1 ratio the transformer primary e. m. f. is practically equal to that of the armature at all times; and the main field, with this primary e. m. f. in series with it, should act just like the field and armature in series in the straight series motor. Assuming a given main field flux, then the armature rotational or counter e. m. f., and consequently the e. m. f. of the transformer, will vary up and down with the armature speed. Therefore

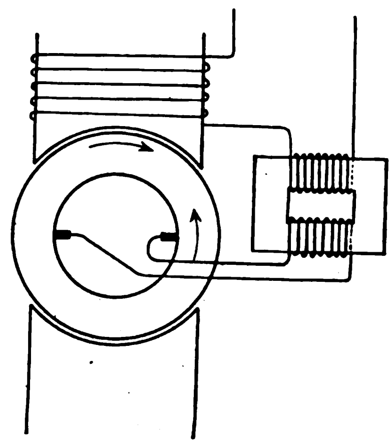

Fig. 10

the magnetic flux of the transformer will thus vary with the armature speed.

The primary current of the transformer necessarily is in phase with the main field current and the secondary current from the transformer will be in phase with the primary, excepting the necessary magnetizing component. The current supplied to the armature will, therefore, be practically in phase with the rotational e. m. f., just as in the straight series motor, excepting the small magnetizing current for the transformer, which is 90 deg. out of phase with the primary current, as is also the flux in the transformer. The secondary e. m. f. of the transformer must be just enough out of 180 deg. phase with the armature rotational e. m. f. to allow the necessary transformer magnetizing current to flow.

Such an arrangement, in general, can replace the straight series motor. It is different from the series motor, in that the armature can be proportioned for its own best voltage and current conditions, regardless of line conditions. It also differs in the fact that the armature furnishes exciting current for the transformer.

It should be noted also that minor effects due to magnetic leakages, etc., are neglected in the above treatment.

In the repulsion type motor, instead of a separate transformer with its own primary and secondary windings, the magnetic circuit of the motor itself is used as a transformer core, and the armature winding is used as the secondary winding of the transformer. Thus the secondary voltage supplied to the motor, and the rotational e. m. f., are both generated in the same winding.

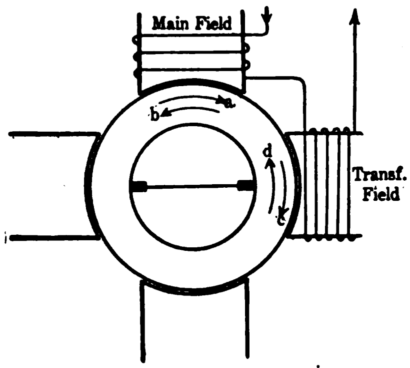

Fig. 11

Fig. 11 illustrates such an arrangement. Here the transformer magnetic circuit is across, or at right angles to, the main magnetic circuit.

In operation, the counter e. m. f. *a* is generated along the brush axis by rotation under the main field. Also, due to the transformer flux, an e. m. f. *b* is generated in the winding along the same axis. If the main current in the transformer winding should generate the transformer flux, then such flux would be in phase with the primary current, and the transformer e. m. f. *b* would be at 90 deg. to the rotational e. m. f. *a*. But this represents an unbalanced condition with the brushes short-circuited on themselves, as in Fig. 11, and heavy currents will tend to flow, correcting the unbalanced voltage conditions. The result of this is a magnetizing current for the transformer magnetic circuit which gives a resultant flux in the transformer pole lagging 90 deg. from that in the main poles. This 90 deg. lag in flux thus throws the transformer e. m. f. *b* practically 180 deg. out of phase with *a*; that is, directly in opposition to it, as described in connection with Fig. 10. Thus there are generated in the armature winding two practically equal and opposite e. m. fs. However, the *fluxes* in the two fields are not equal or equivalent except under certain conditions. The e. m. f. *a* depends upon the main pole flux, and upon the speed, which is variable while e. m. f. *b* depends upon the transformer pole flux, and the frequency of the main system which is constant. When the rotational frequency (revolutions times poles) becomes equal to the line frequency, the two sets of field fluxes become equal, or equivalent, in generating e. m. f., and therefore, the motor is similar to a polyphase motor with its armature rotating at synchronous speed, which, as already described under Polyphase Motors, gives zero frequency and e. m. f. in the rotating armature coils.

Under the condition of equal fluxes the commutation is best, as in the polyphase motor with a commutator type armature, for the coils short-circuited by the brushes have in them a transformer e. m. f. generated by the flux of the main poles, and a practically equal and opposite rotational e. m. f. generated by the transformer poles. Due to these two principal fluxes being 90 deg. out of phase, as already explained, the two e. m. fs. balance each other in the short-circuited coils; which is simply another way of stating the above condition of zero e. m. f. at synchronous speed.

At standstill, the transformer e. m. f. in the short-circuited coils, due to the main flux, exists just as in the series motor, but there is no rotational e. m. f. from the transformer poles to neutralize it. This, therefore, is the same as in the series motor, but between standstill and synchronous speed, the resultant short-circuited e. m. f. falls with increase in speed. The commutation thus improves with speed, much more than with the series motor.

It has been shown in connection with Figs. 10 and 11, that for a fixed main field the transformer field is low at low speed, and increases with the speed until at synchronism, it is equivalent to the main field,—that is, it varies directly with the speed. Let us see the effect on commutation above synchronism. At all speeds the short-circuited e. m. f. due to the transformer action of the main poles, is constant with constant flux, but the rotational e. m. f. in the same short-

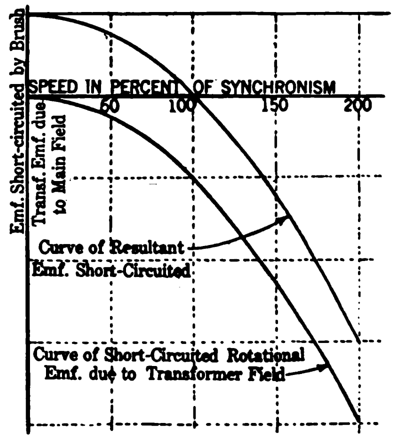

Fig. 12

circuited coils, due to the flux from the transformer poles, increases rapidly with speed, both on account of the increase in speed and the increase in the transformer flux, which also varies with the speed. Consequently, the rotational e. m. f., due to the transformer field, increases as the square of the speed.

These e. m. f. conditions may be illustrated in Fig. 12. Here it may be seen that the resultant e. m. f. under the brush falls slowly, slightly above standstill, but quite rapidly near synchronism. Above synchron-

ism it increases rapidly. At 41 per cent above synchronous speed, it is equal to the standstill value, and at 100 per cent above synchronism, it is three times as great as at standstill. Of course, this is simply an illustrative condition, as the actual values do not follow rigidly the above conditions, the phase relations of the two e. m. fs. not being at exactly 180 deg. But this method of showing the commutating conditions gives a good conception of why the repulsion motor sparks badly at much above synchronous speed.

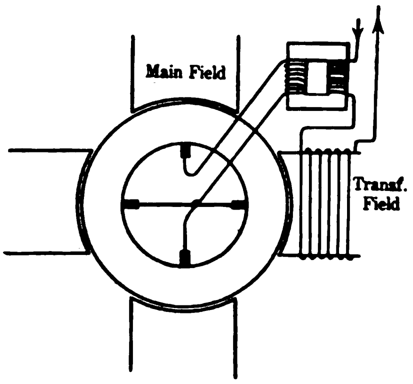

FIG. 13

Armature Excited Repulsion Motor. A modification of the above type is the Winter-Eichberg motor built by the A. E. G. Co. of Germany. This is illustrated in its simplest form in Fig. 13. The only material difference between this form and the repulsion motor shown in Fig. 8 is that the stator exciting windings are omitted and excitation is supplied to the armature instead, by a set of brushes midway between the usual brushes.

To generate the main field flux, it takes a given m. m. f. whether the windings are placed on the main poles or on the armature. However, when placed on the poles the main flux sets up a counter e. m. f. in the field coils at 90 deg. to the current, thus materially affecting the power factor. When placed on the armature, there is a corresponding m. m. f. set up, with the armature at standstill, but, as shown before, at synchronous speed the armature e. m. f. is practically zero; that is,—the exciting m. m. f. can be supplied at practically zero volts, thus greatly improving the power factor. Such improvement lessens, however, with departure from synchronous speed.

Another way of looking at this is that the main flux through the armature winding sets up a 90 deg. displaced e. m. f., just as in a stator exciting winding, but the transformer field sets up, by rotation, an opposing e. m. f., so that the resultant e. m. f. varies from full reactive e. m. f. at standstill to practically zero at synchronous speed.

This motor has practically the same commutation problems as the ordinary repulsion motor except that it has twice as many brush sets. The exciting set, however, does not present much of a problem as far as current capacity is concerned, as the exciting current is relatively small, compared with the normal work current carried by the other set of brushes. The short-circuiting conditions, however, may be the same as for the main brush set. It may be mentioned, before leaving this type, that in practise the exciting current is usually supplied through a small transformer the primary of which is connected in series with the transformer-pole winding.

Doubly-Fed Motor. The above treatment of the repulsion motor leads directly to another later type, which has been used considerably; namely, the doubly-fed motor, as it is usually called. On first inspection this appears to be a combination of the series and the repulsion types, in that the armature is connected in series with the main field winding, and that it also has a transformer field like the repulsion motor. However, the transformer field differs in the fact that it is connected across a section of the main supply transformer, and thus, in reality, is in shunt relation to the armature and main field windings. This allows control of the transformer e. m. f. in the armature winding, and also of the rotational e. m. f. due to the transformer flux. The general arrangement is illustrated in Fig. 14. Here it is seen that the main field and the armature windings are in series, as in the series motor, the transformer winding being across part of the main transformer. In consequence of this shunt connection of the transformer, its magnetizing current is supplied from the transformer, instead of the armature winding, as in the true repulsion motor, and the magnetizing current and flux lag 90 deg. The transformer e. m. f. *b* generated in the armature winding is at 180 deg. to e. m. f. *a*, just as in the repulsion motor, but *b* now can have any value, regardless of *a*, depend-

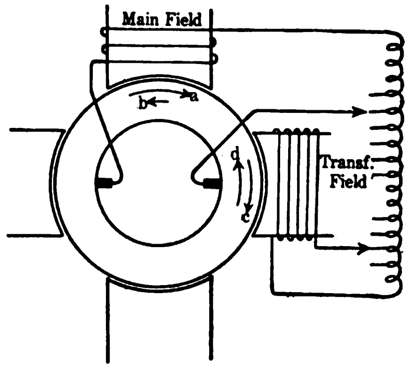

FIG. 14

ing upon the flux in the transformer pole, which is dependent in turn, upon the main transformer e. m. f. supplied to the transformer pole winding. Thus the principal condition of this arrangement is the non-dependence of *b* on *a*, although they are in practical opposition. Their difference appears as an e. m. f. between the brushes. By adjusting the e. m. f. supplied to the transformer winding, to make the e. m. f.

b equal to *a*, the two brushes could be connected together, as in the repulsion motor.

When it comes to commutation, this motor differs materially from the repulsion motor. It is evident that if the transformer pole flux is adjustable in value, then the e. m. f. *d* due to transformer action of the main field can be balanced by the rotational e. m. f. *c* at other than synchronous speed. Consequently, the resultant short-circuited e. m. f. under the brush can have its minimum value at any desired speed, within the limitation of this type of motor. This can be illustrated as in Fig. 15.

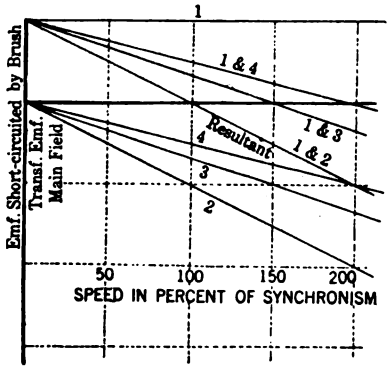

Fig. 15

Assume, as in the repulsion motor conditions in Fig. 12, that the main field is of constant strength. Then the transformer e. m. f. in the coils short-circuited by the brush, due to the main pole flux, is of constant value, as shown in *l* in Fig. 15. However, the e. m. f. in the short-circuit coil due to rotation in the transformer field, is proportional to the speed, instead of the speed squared, for the transformer flux does not vary with the speed, as in the repulsion motor. This is shown as curve *2* in Fig. 15. By weakening the transformer field, the rotational e. m. f. could be changed to 3 or 4. Thus the point of complete neutralization of the two short-circuited e. m. fs. can be shifted to various speeds, and the commutation is thus under better control than in the corresponding repulsion motor. The principal advantage taken of this in is running above synchronous speed, where the usual repulsion motor is bad, as shown in Fig. 12. The method could be used below synchronous speed also, but the flux from the transformer pole would have to be larger than that in the main poles, which, in general, means a larger machine. As a matter of simplicity in control, such motors are sometimes operated as repulsion motors below synchronism, and as doubly-fed at the higher speeds, where weaker transformer fields are used.

In practise, in order to reduce the short-circuiting at start and low speeds, it is not unusual to weaken the main field a small amount, possibly as much as 25 per cent to 30 per cent. This simply helps the low speed conditions, but does not have any material effect at the higher speeds and the main field is restored to normal value by the time any considerable speed is attained.

The Commutating Pole Series Motor. The next step from the doubly-fed motor is to the series motor with commutating poles with phase displacement. In fact the doubly-fed motor with its adjustable transformer pole strength may be defined as one form of commutating pole series motor. The commutating pole series motor, proper, is simply a series a-c. motor, with main and compensating windings in series with the armature and with small commutating poles in addition, as shown in Fig. 16. The commutating poles may generate a small opposing e. m. f. *b* in the armature winding, but on account of the small size of the poles themselves, this effect is almost negligible, compared with the doubly-fed motor, and it is opposed by a corresponding e. m. f. in the compensating winding. However, it is intense enough, in its flux, to set up the necessary opposing e. m. f. in the short-circuited armature coils. By suitably exciting it in the 90 deg. relation, as in the doubly-fed motor, it can do what the latter motor does, and in addition, can be over-excited below synchronous speed, without the disadvantages of the transformer pole in the doubly-fed type, as its total flux is quite small, in comparison. Thus it can give considerable correcting effect at quite low speeds, which is a material advantage. Furthermore, by exciting at some other than the 90 deg. relation, it can also be made to assist in neutralizing the so-called reactive voltage of the armature (corresponding to d-c.). For this latter the commutating pole flux should be

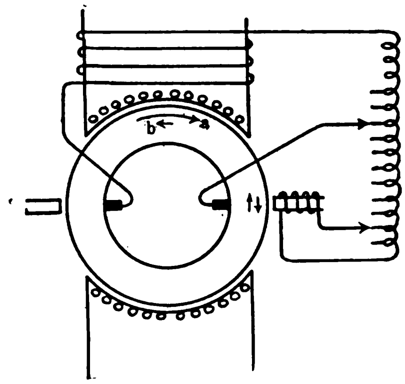

Fig. 16

more nearly in phase with the main flux. Consequently by exciting the small commutating poles by a combination of series and shunt connections, an average best condition is obtained; but this changes with the speed, and must be adjustable for best results. One relatively simple and effective means for obtaining the desired phase-shift, in the commutating poles, is by means of a series winding on these poles, this winding being shunted by a suitable resistance. This arrangement, patented by Latour, has been used to a considerable extent in Europe, especially by the Oerlikon Company.

The foregoing descriptions cover only the general arrangements of single-phase series type motors, with regard to commutation. Many variations have been tried out from time to time, but it is beyond the scope of this paper to go into all such methods. Latour and Alexanderson have been pioneers in the doubly-fed type and they have devised most excellent schemes and methods, both for this and other types, which, in principle, are embodied more or less in the preceding descriptions.

Single Phase Commutator Type Induction Motors. These are of various types resembling, in many ways, the polyphase commutator and the repulsion types already described. However, an analysis of one characteristic type, from the commutation standpoint will be sufficient. The so-called repulsion induction type will be considered, as it bears a very close resemblance in many ways to the repulsion and the doubly-fed motors. An illustrative arrangement of such a

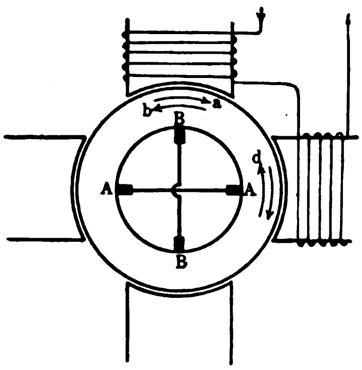

Fig. 17

motor is shown in Fig. 17. It has been shown in connection with Fig. 11 and the repulsion type motor, that at synchronous speed of the armature, with respect to the line frequency, there is zero frequency in the armature winding. The e. m. fs. a and b are balanced and so are e. m. fs. c and d, due to transformer action of the main flux and the rotational e. m. f. from the transformer flux. Consequently, under this condition, another pair of brushes, short-circuited on itself, could be placed at right angles to the repulsion motor brushes, or in fact, could be placed anywhere. Let us assume them at the right-angle position.

In the repulsion motor, at other than synchronous speed, the main field and the transformer fluxes are unequal, or not equivalent, as brought out fully in the former description. Under such conditions e. m. fs. c and d will be unequal and the addition of the second set of brushes, shown in Fig. 14, would result in a considerable current flow. This will be in such direction and value as will equalize e. m. fs. c and d, or in other words, *it equalizes the flux values of the main and transformer poles*, so that the motor maintains practically synchronous speed over its operative range,—that is, it operates very much like an induction motor. Obviously this represents quite good commutating conditions, as in the repulsion motor at synchronism.

Like the doubly-fed motor, balanced voltage conditions can be obtained at the repulsion motor brushes, at other than synchronous speeds, by the introduction of an e. m. f. at the repulsion motor brushes. Assume, for example, that an e. m. f. of proper phase relation with a value of 20 per cent of b is introduced, thus making b equal to 120 per cent of a. To balance this, the speed should rise, or the main field should strengthen, or the transformer flux should weaken, or part or all of these may modify in value. Let us assume, as a rough approximation, that the speed rises 10 per cent, the main field is strengthened 5 per cent and the transformer flux weakened 5 per cent. Then e. m. f. a becomes 115 per cent, due to the speed and the stronger main field, while b with its 20 per cent addition is reduced to 115 per cent by the weakening of the transformer field, thus balancing these two voltages. Then d due to the transformer action of the 5 per cent stronger main pole, becomes 105 per cent and c due to 110 per cent speed and 95 per cent transformer pole flux, becomes 105 per cent also, thus giving balanced voltages between the rotational and the transformer actions. Here we have unequal voltages along the two axes. As far as commutation is concerned, there is practically a balance in the short-circuited e. m. fs. under the A set of brushes. However, it is obvious from the above, that under the B set the two e. m. fs. do not balance and the unbalance increases with departure from synchronous speed.

Polyphase Series and Shunt Motors

a. Series Motor. The polyphase series motor differs from the polyphase induction motor with commutator, in the fact that the counter e. m. f., opposing the primary impressed e. m. f., is not generated in the primary winding, but is generated directly by the armature, as in a d-c. series motor. It resembles the single-phase series motor, in that the total current in the primary winding becomes magnetizing and the e. m. f. generated in the field and armature windings must sum up vectorially to the line impressed e. m. f. Assuming as the simplest case a two-phase series motor, this may be considered roughly as two single-phase motors, structurally at right angles, and with a common armature. This is illustrated in Fig. 18.

In the circuits between brushes A_1 A_1, two e. m. fs. are generated, a due to rotation in field A and b due to transformer action of field B.

As in the polyphase motor, illustrated in Figs. 1 and 2, a can be considered in the nature of an armature counter e. m. f. and b as an impressed e. m. f., in this case adding to the line e. m. f. However, the addition of compensating windings on the field structure affect this condition. Such windings are added primarily for neutralizing or compensating the armature m. m. f. along the axes $A_1 A_1$ and $B_1 B_1$. Diagramatically,

around the B pole or flux there should be compensating windings in phase with the A phase armature windings, but opposing. Practically they would be connected in series with the A phase. The effect of the B flux on the A phase compensating winding is to generate in it a transformer e. m. f., practically equal and opposite to the transformer e. m. f. b in the armature. This was referred to briefly in connection with the commutating pole series motor, Fig. 16. In consequence, as a resultant, there is left only the rotational or counter e. m. f. a, as in the series single-phase motor.

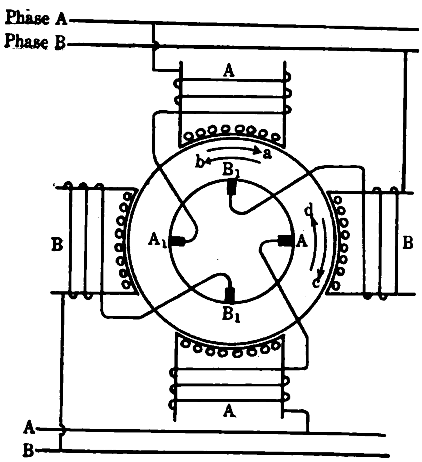

Fig. 18

Phase B with its poles, armature winding, etc., can be treated just as phase A; and thus it is seen that such a motor is quite similar to two superposed single-phase compensated motors with their torques at 90 deg. Thus such a motor will not have the pulsating torque of the single-phase series motor.

In such a motor the commutating conditions are quite similar to those of the single-phase motor at standstill conditions, but are much better as synchronism is approached, just as in the polyphase induction motor with commutator. While the transformer e. m. fs. b and d are opposed by similar e. m. fs. in the respective compensating windings, so that their resultant effects between machine terminals are practically zero, yet the two component e. m. fs. remain in the windings,—so that in the armature, for instance, a opposes b in the coils under the B_1 B_1 brushes and c opposes d under the A_1 A_1 brushes. As synchronism is approached, these opposing e.m.fs. in the coils short-circuited by the brushes more nearly balance each other, just as in the polyphase induction motor with commutator. The conditions of commutation are therefore similar to those in the polyphase commutator motor.

b. Shunt Motor. The polyphase shunt type commutator motor is quite similar to the polyphase series type, except that the field windings are either shunt or separately excited, as shown in Fig. 19. The respective armature and compensating circuits (not shown) are in series and their currents are practically in phase with their rotational e. m. fs. and field fluxes. The field windings being shunt (or separately) excited, must therefore have their exciting e. m. fs. practically 90 deg. out of phase with their respective armature rotational or counter e. m. fs., the A poles being excited from B phase, as shown in Fig. 19. With shunt excitation from constant e. m. f. sources, the field fluxes thus are practically constant, so that such motors tend to maintain constant speed, unlike the series type. The conditions of commutation are so similar to those of the series type that further discussion is unnecessary.

In the above treatment of the polyphase series and shunt motors, the e. m. fs. generated by rotation in the main and in the transformer fields, and also by transformer action due to both fields, have been considered, but there is no reference to the e. m. f. due to the armature field corresponding to that in d-c. commutation. However, as was stated in connection with polyphase induction motors, this e. m. f. is usually quite small, compared with the maximum values of other e. m. fs. short-circuited by the brushes. It is true that where the rotating and transformer short-circuited e. m. fs. practically balance each other, as is the case near synchronism, the e. m. f. due to the armature field may predominate. However, this is in the best part of the commutating range.

In general, the low-voltage, one-turn, parallel-type armature winding and the special proportions used in such machines to obtain desirable conditions otherwise, all tend toward extremely good commutating characteristics on the basis of direct-current commutation,—much better than the average commercial d-c. machines

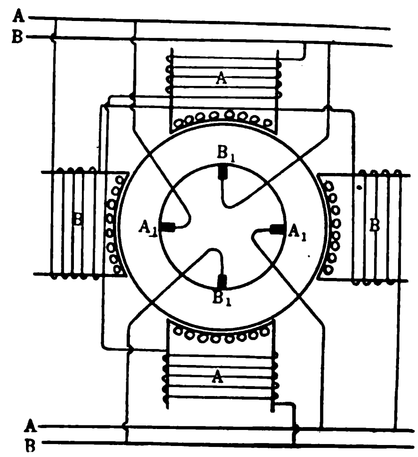

Fig. 19

of the same capacity. Moreover, the e. m. f. under the brushes, generated by the armature field, is usually out of phase with the other short-circuited e. m. fs., or their resultant, so that its inclusion would mean but little change in the problem. Therefore, it has been neglected throughout this entire method of treatment.

It should be noted in connection with the above series and shunt motors, as well as in all of the preceding descriptions, that in splitting up fluxes, m. m. fs., etc., into certain components, it is only for purposes of

illustration and easy explanation. The actual conditions in the machines themselves may be quite different,—for example, where there are two or more currents in a given armature winding, their effects may appear as one resultant m. m. f. of a certain phase relation. The same may hold true for magnetizing, compensating and other windings, and in place of two or more components, a single winding may be used in practise. Also instead of the main and the transformer fluxes acting independently, at any instant there is simply one resultant or combined flux, etc.

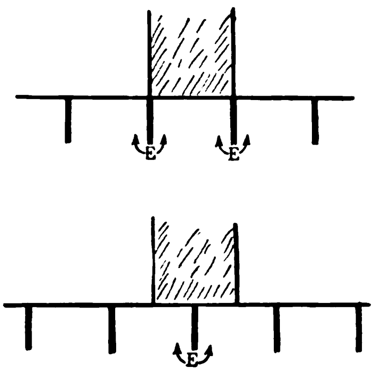

FIG. 20

In the foregoing treatment of the a-c. commutator motors, it should be evident, especially in the case of the polyphase motors, that both speed control and the commutation are dependent upon the relation between the transformer and the rotational e. m. fs., the speed control taking into account the e. m. fs. in the full winding, whereas the commutation involves only that part of the e. m. f. short-circuited by the brushes. This general idea of the relationships of the two characteristics may be expressed in another form,—namely, speed flexibility in induction motors involves change in frequency, which in turn involves the commutation problem in most of the methods and devices used.

In the foregoing treatment of the a-c. commutator motor, the e. m. f. short-circuited by the brush has not been considered in the quantitative sense,—that is, no operative values or limits have been given and the subject would certainly not be complete without some data of that nature. The actual limitations of commutation in a-c. as well as d-c. commutating machines, is fixed principally by the maintenance and life of the brushes and commutator. These depend largely upon the losses due to commutation and the means for preventing harmful effects due to such losses.

COMMUTATION LOSSES AND COMMUTATOR WEAR

It is desirable at this point to consider some of the losses due to the short-circuited e. m. fs. under the brushes in a-c. commutating machines. In the preceding treatment of the rotational and transformer e. m. fs. short-circuited by the brush, apparently it was a question of total volts short-circuited, regardless of the volts per commutator bar. From this view-point, as treated, the number of bars per brush did not come into the problem. For instance, if a given e. m. f. were short-circuited by the brush, this e. m. f. might be generated in one coil of three turns connected to one commutator bar, or in three coils of one turn, each connected to one bar. But a little study of the problem from the standpoint of losses in the brush contact surfaces, as given below, shows this is not so, and that the number of bars short-circuited by a given width of brush may be of considerable importance.

At first glance, one would say that the loss due to the short-circuiting of a given e. m. f. by the brush is simply a question of the value of the e. m. f. and of the brush contact resistance, and that the number of bars spanned is of no consequence as long as the total short-circuit e. m. f. is the same. However, the following results show wherein the number of bars may have a very considerable effect. For example, let us take the case where an e. m. f. E is spanned by the brush. If the brush is the width of one commutator bar, then the average loss is materially larger than if the brush spanned two bars of half width with 0.5 E volts per bar. These two cases can be illustrated by Figs. 20 and 21. In Fig. 20, two positions of the brush with respect to the commutator bars are shown, in one of which the brush short-circuits no e. m. f., while in the other there is the maximum short-circuiting of e. m. f. E. The loss at the brush contact varies from a minimum of

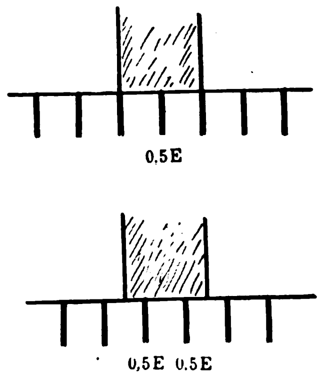

FIG. 21

zero, to a maximum with the brush midway over two bars.

In Fig. 21, two positions of the brush are shown, in one of which the brush spans just two bars, but short-circuits only the e. m. f., 0.5 E, while in the other it is in contact with three bars, and spans a total e. m. f., E. This latter position is that of maximum loss, while the first position shows a minimum, but not a zero, loss. As stated before, it would appear, without analysis, that the average total loss would be practically the same as in Fig. 21. But calculation shows that the average total of the first case is 60 per cent greater than

in the second.[3] The general result is indicated in Fig. 22. It appears from this loss curve that there is but little gain, with more than two bars spanned. Also, it usually is thought that the losses would be decreased, with the brush spanning less than one bar. This, of course, is true with a *given volts per bar*, but is not the case with a *given average voltage short-circuited by the brush*, which is the condition where the short-circuit e. m. f. is determined by the primary fields, instead of the armature fluxes.

This question of losses depending upon the number of bars spanned, may also have a bearing on certain results noted in d-c. machines.

The losses due to commutation are dependent upon the voltages short-circuited and the current values and distributions at the brush contact and in the leads

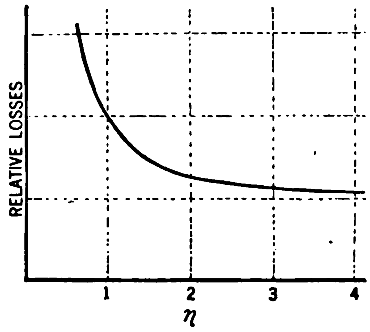

FIG. 22

and coils short-circuited. In "resistance lead" motors or in small motors with relatively high resistance in the coils themselves, a considerable portion of the total resistance in the short-circuited path may be in such parts, thus relieving the brush contact except where the short-circuited e. m. f. is purposely increased with such resistance in circuit.

In all practical a-c. commutator motors the sparking and burning action at the brushes appears to be greatest at starting, and at the lower speeds during acceleration. This is particularly noticeable under those conditions, such as railway work, where the torque at start and at low speed is highest, decreasing with increase in speed consequent upon decrease in main field flux. But even with constant torque the sparking appears worse at lower speeds. With those types of a-c. motors with neutralizing e. m. fs. dependent upon speed, the sparking and deleterious effects on the commutator and brushes decrease with speed up to fairly high speeds. Herein lies one reason why such machines can be made operative without resistance leads even for quite frequent acceleration, as experience has shown. It is because the more severe sparking conditions last for shorter periods than in the non-commutating-pole resistance-lead types; otherwise, the brush contact surface would tend to burn badly and the commutators would blacken due to such burning action. Herein, also, is one reason why the commutating-pole type railway motor, shown in Fig. 16, gives such good brush and commutating conditions. As stated in the description of this motor, the correcting effect of the commutating pole can be carried down to quite low speeds without undesirable effects otherwise.

The real measure of the permissible short-circuited e. m. fs. must be in the operating characteristics, as they affect the commutator and the brushes. Sparking in itself is not harmful in either a-c. or d-c. machines, unless the commutator and brushes show undue deterioration, or require more than usual attention. The so-called "wear" of the commutator copper and the brushes, usually is not true mechanical wear, but is the result of burning at the contact surfaces. All commutating machines are subject to such "wear" in varying degree. Where the burning or wear is at an extremely low rate, the scouring action of the brushes usually will wear down the commutator mica as fast as the copper surface burns away, so that the brush keeps in intimate contact with the copper. In those cases where the rate of burning exceeds the mechanical wear, the mica will ultimately project above the copper and thus "high mica" will result. As soon as this begins, *even in the slightest degree*, the burning action is accentuated, for the brush makes less intimate contact with the copper surface, thus further increasing the burning action. This explains why, in the great majority of cases where commutator burning or undue wear occurs, undercutting the mica makes a very positive improvement,—in many cases apparently entirely eliminating the commutator wear, due to the better contact between the brushes and commutator. This is especially true in railway motors, both d-c. and a-c. and modern practise has tended almost exclusively toward undercutting the mica in such apparatus. Under-

3. The relation of average total loss to the average bars spanned by the loss can be expressed mathematically as follows:

Let e = the e. m. f. per bar.
n = number of commutator bars spanned.
Then $n\,e = E$ = total e. m. f. spanned by brush.
Let r = resistance of brush contact for unit area.
W = width of brush face.

$$\text{Total loss} = \frac{E^2 W}{12\,r}\left(\frac{n^2+1}{n^2}\right)$$

For comparative loss, with $n = 1$, then $\frac{n^2+1}{n^2} = 2$

$$n = 2,\ \frac{n^2+1}{n^2} = 1.25$$

$$n = 3,\ \frac{n^2+1}{n^2} = 1.11$$

$$n = 4,\ \frac{n^2+1}{n^2} = 1.06$$

$$n = \infty,\ \frac{n^2+1}{n^2} = 1.00$$

cutting is particularly beneficial in the former d-c. noncommutating pole types where the short-circuited voltages under the brushes sometimes reached quite high values. In the same way, in a-c. commutating motors, where there are often quite high voltages under the brushes, and a relatively high percentage of mica due to the large number of commutator bars, undercutting of the mica is a practical necessity in all, except, possibly, quite small machines. Even in well designed d-c. machines, other than for railway service, where the mica represents materially above 20 per cent of the commutator wearing surface, experience has shown that undercutting may be needed, even with quite well-proportioned commutating poles. It is obvious, therefore, that the e. m. fs. which can be short-circuited without harmful effects, will vary greatly, depending upon the percentage of mica.

Experience has shown that the burning of the commutator and brushes is largely dependent upon the watts expended at the contact surfaces, as should be expected. Many years ago the writer obtained valuable results from a long series of tests on the collector rings of a uni-polar generator,[4] to determine the rate of wear due to current and contact conditions. It was found that increased contact drop, as well as increased current density, would result in increased wear of the rings and brushes, and that the rate of wear was some function of the actual loss. With a given current density, the contact drop would vary, depending upon the formation of a coating or film under the brushes or on the rings, and if such coating was of appreciable resistance, the contact drop would increase, with corresponding increase in the rate of wear.

In consequence of this condition of wear, due to the losses in the contact, the actual current densities in the brush contacts, as well as the e. m. fs. short-circuited, should be taken into account. But as the local or short-circuited current is a large element in the current density in most a-c. commutation, and as this local current in turn depends upon the e. m. f. short-circuited it so happens that the short-circuited e. m. f. in itself very largely fixes the limiting conditions. Furthermore, as it is largely a question of permissible losses, the peak value of the short-circuited e. m. f. should not be used, especially in comparing a-c. and d-c. limits, but rather some mean value which represents more nearly the average loss conditions.

Commutation Limits. It should be evident from what has already been given that it is quite difficult to fix, even approximately, permissible e. m. fs. which may be short-circuited by the brush, either in a-c. or in d-c. machines. The grade of brush used, the condition of the commutator, the duration of the commutating period, along with many other conditions, all have a bearing on the problem. The short-circuited e. m. f. can be above the harmful point if followed by a sufficient period of scouring action. Starting and acceleration, representing the severest conditions, may be frequent in one case and very infrequent in another. The whole problem is more or less a question of averages. Unless all the conditions are taken into account, there are many apparent discrepancies.

Approximate limits for three operating loads are given in the following table:

(a) Load permitting continuous operation without undue deterioration of the commutator and brushes.
(b) One-hour loads followed by period of lighter operation.
(c) Momentary or very short period load which would be quite destructive if continued for any considerable length of time.

Type of apparatus	Effective e. m. f. Short-circuited		
	Load (a)	Load (b)	Load (c)
D-C. non-commutating pole traction motor (average of 9 sizes)	5 to 7	9 to 11	14 to 17
D-C. engine type Generators (non-commutating pole)	5 to 6	7 to 10	..
Special d-c. 3rd-brush motor—200 h.p.	5 to 6		
A-C. traction motors—doubly-fed and commutating pole types	5 to 6		12 to 14
A-C. traction motors—resistance lead, non-commutating pole types	7.5 to 9	9 to 11.5	13 to 15
A-C. industrial motors	5 to 6.5		
Frequency changers	5 to 6.5	8 to 10	

The above results were obtained from a comparatively large number of machines of each class, except in the case of the third-brush machine cited. This special instance is given, for here a very definite e. m. f. was short-circuited under an active field and good limiting figures were obtainable.

In the case of the d-c. traction motors, the limits given are on the basis of full-line e. m. f. impressed on the motor. Under this condition with load (*a*) the commutator would polish quite well, while on load (*b*) practically all these motors showed some signs of "smutting" at their commutators and the brushes not infrequently showed evidences of burning. Load (*c*) for these motors corresponded to 200 per cent of the one-hour current rating. However, the assumed condition of full-line voltage on the motor is not a normal railway motor operating condition, for, in general, such motors handle these excessive currents only during starting and acceleration,—that is, at reduced speeds with correspondingly reduced e. m. fs. under the brushes.

It might be asked, here, how it has been possible for the d-c noncommutating pole traction motors to operate satisfactorily with as high as 10 volts under the brushes, at more or less frequent intervals, and still continue in good operating condition. In reply, it may be stated that in traction work, there are, in general, considerable periods of coasting, or light service, in which the scouring action of the brushes on the commutator is sufficient to counter-balance the harmful effects of the

4. *Development of a Successful Direct Current, 2000-Kw. Uni-Polar Generator*—Trans., A. I. E. E., June, 1912.

heavier periods. Moreover, experience has shown that the effect of burning under the brushes at heavy loads on these traction motors has been such as to tend to narrow the effective contact face of the brush, thus automatically lessening the average short-circuited e m. f. and the tendency to burn. Also in railway motors which reverse their direction each trip, not uncommonly the brushes tilt slightly in their boxes, depending upon the direction of rotation, so that the brush contacts show two distinct surfaces, each of half the brush width, thus narrowing their effective contacts, and protecting themselves.

In d-c. generators the extreme conditions of short circuit were found, in many cases, where the brushes at no-load were given the greatest possible forward lead in order to take care of the widest range of load without further brush shift. Not infrequently the brushes were shifted into magnetic fields corresponding to five to seven volts across the brushes, or even higher, depending upon the amount of sparking which was considered permissible. Judging from a large number of cases, five to 6 volts short-circuited did not represent an unduly difficult condition.

In the a-c. traction motors of the doubly-fed and commutating-pole types, it has been quite difficult to obtain any very definite data, for here the short-circuit conditions change with the speed and with the adjustment of the compensating windings, and therefore, only average results could be obtained. However, in the a-c. traction motors of the non-commutating-pole type, but *with resistance leads*, quite definite data was obtainable. It will be noted from the table that here the limiting conditions for continuous operation are quite considerably higher than in other types of apparatus, thus indicating quite clearly that the resistance leads, as used, were quite effective in limiting the local currents. On the hour rating, as indicated in column (*b*), these motors do not show materially better than the non-commutating-pole d.c. motors, except that possibly in some cases the "smutting" was a little less pronounced.

The data in the above table, for a-c. industrial motors, were compiled from quite a series of small motors, mostly of variable speed. Here the general results are also somewhat conflicting, but in practically all cases examined, the permissible range of continuous operation was within the figures given. A number of instances were noted where the short-circuit conditions were up to eight or nine volts with apparently fair commutating conditions, but which eventually showed such evidence of deterioration that they were not considered satisfactory. Changing the design of such motors to reduce the short-circuit e. m. f. below the 6.5-volt limit usually made them quite satisfactory.

A number of frequency changers have been built for operation in the secondary circuits of large induction motors for speed control, and fairly definite limits have been obtained from these, as indicated in the above table. Some of these machines have shown quite good commutation at much higher voltages, but after a considerable period of operation, even without visible change in the commutation itself, the brushes would show signs of burning away a part of the contact surface. In such cases, therefore, the real operating limits appear to be in the action under the brushes, rather than in the *visible* commutation. In fact, this was true in many of the cases which were investigated in both d-c. and a-c. machines. The writer has seen many machines of both types, which showed sparking at the brushes, but which showed no evidence of serious burning under the brushes. Conversely, he has seen many cases where the commutation was apparently quite good, but in which there were evidences of more or less rapid deterioration. Thus it may be said that visible commutation is not always a true measure of the permissible short-circuiting action.

An interesting feature of the above table is the fairly close agreement between limiting e. m. fs. for the various types of apparatus. While the writer has felt all along that both a-c. and d-c. commutation were dependent upon approximately the same limits, yet until this paper was undertaken, he had never gone into the comparison as fully as covered in the above table. In former instances, individual cases had been compared, but no attempt had been made to analyze any considerable lines of machines in order to compare the general results. An interesting fact that developed in this study was that a number of machines, which apparently exceeded the above limits, were found, upon further investigation, to have proved somewhat questionable in their operation, after a fairly long period of service.

Isolated cases were found, also, which did not fit in closely with the table, but, as already indicated, no hard and fast rules can be drawn, on account of the large number of variables in the problem.

This paper does not attempt to cover all the characteristics of a-c. commutator motors, but may be considered simply as a review of certain general conditions which affect commutation and speed control. Furthermore, it does not attempt to cover the design of such apparatus. Any wide departure from its present scope would lead into the realm of mathematics, with corresponding reduction in the readability of the article, as far as concerns the great majority of engineers.

Automatic Railway Substations

BY FRANK W. PETERS

Railway & Traction Engineering Dept., General Electric Co., Schenectady, N. Y.

This paper reviews the broad range of conditions to which railway automatic substations have been applied and also discusses the economies and operating advantages effected by their use. A description is given of the modern equipment with details of its operation. Special reference is made to improvements in design of control apparatus, to the positive sequence of starting the machines and the protection afforded the apparatus against overloads or other irregularaties either outside or internal to the stations.

PRESENT day railway conditions are such that any improvement leading to the reduction of invested capital or decreased operating charges is of vital importance. Automatic substations as shown by several years' operation have resulted in decided economies and improved operating conditions, and as the subject has not been presented before the A. I. E. E. since an account[1] of the original installation was prepared a review of the modern automatic equipment seems desirable.

The first automatically controlled railway substation was placed in service during December 1914, on the Elgin & Belvedere Electric Railway. The station equipment prior to being made automatic consisted of a single 300-kw., 600-volt, 25-cycle, three-phase synchronous converter with three single-phase 110-kv-a., 26,000-370-volt self-cooled transformer and standard manually-operated switchboard apparatus. The individual devices comprising the first equipments were with but few exceptions, those which had previously been developed by electrical manufacturers for use in other applications. This condition was a decided advantage to the operating companies since developmental charges were eliminated, rendering the equipments comparatively low in cost, which in addition to the successful operation of the early installations made possible the rapid growth of automatic application to electric railways.

Shortly after the initial installation on the Elgin & Belvedere Electric Railway, the two remaining substations on that road were made automatic, followed by the Potomac Electric Power Co. which made automatic a 500-kw. substation. About that time (1916) the Des Moines City Railway and Interurban Railway Co., two adjacent roads, outlined and have practically completed a program involving automatic substations, which has resulted in the most notable example of their use up to the present time. These roads now have in operation a total of three 300-kw. and nine 500-kw., 600-volt automatic synchronous converter equipments. The confidence inspired in the minds of operating engineers and the rapid adoption of this comparatively new phase of electric railway operation was in no small measure accelerated by the successful performance of this rather broad application.

The range of requirement to which the new scheme could be successfully applied was demonstrated when in 1917 two 300-kw., 600-volt, 25-cycle synchronous converters operated in series on 1200 volts by the Milwaukee Railway & Light Co. were automatically equipped. Two automatic substations each containing one 600-kw. 1500-volt d-c. induction motor-generator set were also installed in 1919 by the Salt Lake, Garfield & Western Railway. The Rhode Island Co. have for some time been operating a station containing two 300-kw., 600-volt converters in parallel, while in other localities portable automatic substations have been functioning successfully. Railway converters now automatically equipped range in size from 200 to 1500 kw. with motor-generator sets from 300 to 2000 kw. The total capacity operating in this manner and including those in process of installation is estimated to be 45,500 kw. while the number of automatic equipments involved is approximately 79, 59 of which having been applied to 300- and 500-kw. sizes, and the remainder cover the range of various types and sizes of installations briefly referred to.

While it is the intention to confine the scope of this paper to railway activities, it is interesting to note that a hydroelectric station on the Iowa Railway & Light Company's system containing three 500-kv-a. synchronous generators has been operated automatically since 1917 while the Interstate Light & Power Co. in the same year placed in operation a 3000-kv-a. automatic synchronous condenser. The Union Electric Light & Power Co. is applying the scheme to a 2000-kw., 250-volt lighting synchronous converter. Railway operation, up to the present time, has presented apparently the most attractive field for the use of automatic features, but a well grounded start in other lines has been made and it is only reasonable to expect considerable activity in the lighting and hydroelectric branch of the industry.

Without question a direct reduction in operating expense has been the prime motive for the purchase by railway companies of automatic substations. The saving is effected in several ways, although it is a variable and depends on conditions under which a particular station is operated as well as the number and capacity of machines in the station.

Labor Saving. Considering the several items of saving more or less in their order of importance, the matter of eliminating operator's wages stands out most prominently. In those localities where three eight-hour

shifts are in force in single-unit substations the labor saving alone from automatic operation will often wipe out the original cost of the equipment in two to three years. Where only one or two station attendants are employed, as generally the case on the average interurban system, the net return is not so great, but usually is sufficient to represent a desirable return on the investment in extra equipment incident to automatic operation. When two or three machines are installed in a single station an equal number of complete automatic units are necessary, requiring two or three times the initial investment of a single-unit station. This fact makes it more difficult to justify automatic operation of such a station if only the saving of station attendant's wages is considered. A further study, however, of other savings and advantages inherent to automatic operation as applied to a specific case may show economy of sufficient magnitude to warrant two-unit automatic substations.

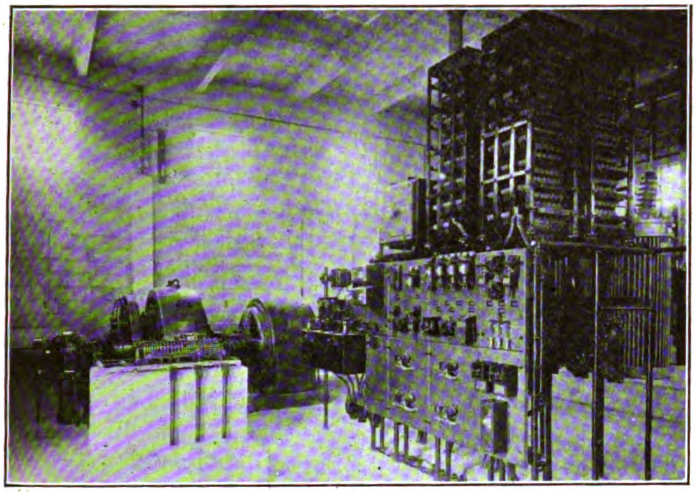

Fig. 2—Interior View of Automatic Substation Containing 600-Kw. 1500-Volt D-C. Induction Motor Generator Set—Salt Lake, Garfield and Western Ry.

The procuring of competent labor constitutes one of the trying difficulties which operating companies have had to contend with during recent years. A natural result of such a condition as applied to manually operated substations is a poor handling of apparatus with a corresponding increase in maintenance costs and less efficient operation. The substitution of automatic stations for the manually operated types eliminates this difficulty in the proportion to the extent of substitution and also reduces the ill effects resulting from labor difficulties. While these features are assets, they are somewhat intangible and not easily capitalized.

A complete elimination of all labor charges against these stations is not feasible since a regular system of inspection must be maintained. Some companies include this work as a portion of a patrolman's or other workman's duties, while other companies which operate several of these stations employ a man who devotes his entire time to this phase of the work. Those stations having high-tension aluminum-cell lightning arresters require daily visits by an inspector to charge the arresters, at which time a casual inspection of the automatic equipment may be performed so as to preclude any minor irregularities becoming serious. Where a reliable high-tension arrester is used which does not require charging such as the oxide film type, two or three hasty inspections per week have been found ample. At intervals of approximately two weeks a thorough inspection should be made and a detailed report prepared to indicate the condition of every device. The amount charged against each station for this service, including maintenance as reported by several companies, varies considerably but will average approximately $300.00 per year.

Light Load Savings. Saving in light load losses, due to automatically shutting down a station when little or no power demand exists, is most noticeable on interurban roads maintaining an infrequent headway. Often a station in manual operation will run idle from a quarter to half the total operating time particularly so if the schedule results in train passing points in the immediate vicinity of the substations. In the event passing points are between stations the machine shutdown period will be somewhat reduced. The total energy saving from this source as applied to single-unit interurban stations depends upon the track layout, characteristics of the schedule and energy required to idle the machine which for a 500-kw. converter equipment is approximately 16 kw.

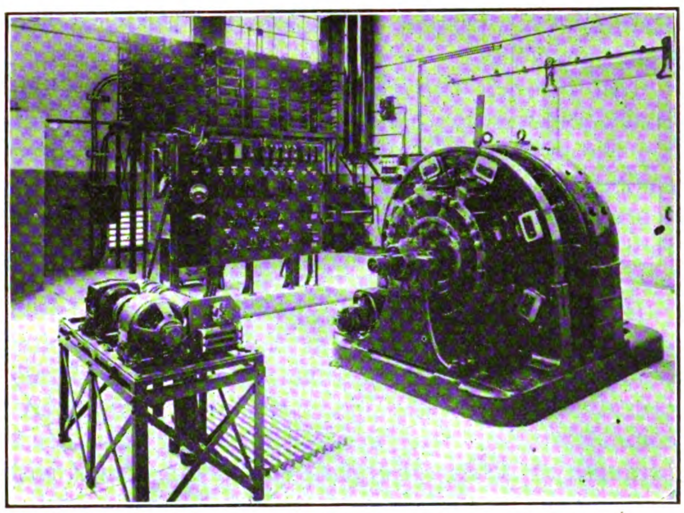

Fig. 3—Interior View of 1000-Kw. 600-volt Synchronous Converter Automatic Substation—Pacific Electric Railway

Energy saving in interurban stations having two machines automatically operated may work out to be very attractive especially if the second machine is used to help out on rush service or move occasional heavy express or freight trains. With automatic operation the second machine would cut in only when a demand for additional power existed and would drop

out when not required. Prompt action in this respect is a decided factor in economy which while not entirely overlooked in the average manually operated substation, is a possible saving considerably neglected.

Two Unit Stations. Combining the savings accruing from the elimination of labor and light-load losses in two-unit parallel-operated automatic stations, together with other advantages, the arrangement is justified as evidenced by the operation of the two-unit station on the Rhode Island Company's system as well as a station now being installed by the Dayton & Troy Electric Railway Co. containing two 300-kw., 600-volt converters and a station on the Cleveland, Railway Co.'s system containing two 1500-kw., 600-volt converters.

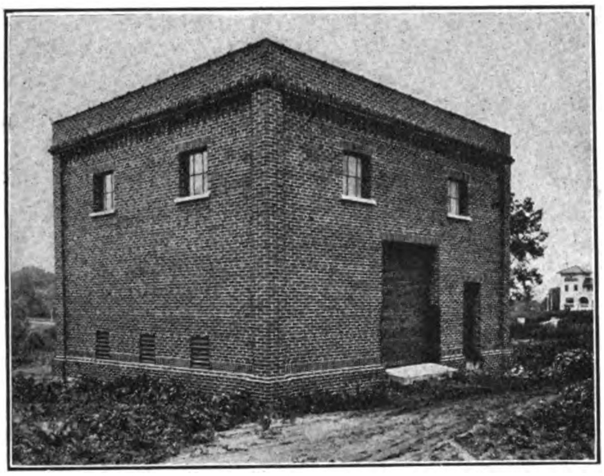

Fig. 4—Exterior View of Polk Boulevard Automatic Substation Containing 500-Kw. 600-volt Synchronous Converter—Des Moines City Railway

Coal Saving. The elimination of coal or perhaps considerable energy used by electric radiators for heating the station or operator's booth is another direct saving attributed to automatic equipments. In the more northern localities this item is sufficient to warrant consideration especially in view of the scarcity and price of coal prevailing in recent years.

Building Design. Building design best to accommodate automatic substations as shown in Fig. 4 is often materially different than that common to manually operated stations. Simplicity, with resulting lowered initial cost, seems to predominate. The structure is arranged to house all apparatus indoors, which with locating the windows out of reach affords a protection from vandalism. Ample ventilation is provided by louvers located in the side walls near the floor level and ventilators in the roof.

Load Factor Improvement. It is a well-known fact that the load factor on the average interurban substation is exceptionally low. Otherwise expressed, this means an unusually large investment in electrical apparatus compared to the average all day power delivered from the station. This condition arises because sufficient capacity must be installed to accommodate not only the regular service, but also to take care of excess demands usually of short duration such as results from accidental bunching of train, snow plows or occasional heavy freight trains. These irregularities because of their rather brief demands on any one station do not, for heating limitations necessitate greatly increased substation capacity, but they do severely tax the station apparatus from the point of commutation and short period capacity. Since in the past there has been no alternative but to provide large capacity machines to protect against these contingencies, the condition of low load factor resulted with high investment charges for the average energy delivered.

The automatic substation functions in a manner partially to remedy the situation so that the average load approaches the maximum load demand on the station, which condition permits increased traffic being served by a given substation or conversely permits a smaller substation capacity to serve a given traffic. This condition is brought about by inserting a high-capacity resistance in the direct-current side of the machine at times of severe overload. The direct purpose of the resistance is to limit the current delivered to a reasonable value, which prevents the abuse of apparatus arising from any load demand. The effect of this device is to cut off the high current peaks so frequent to substations serving rush service, locomotives, heavy freight trains or other requirements where the momentary demands tax the commutation capacity of the machines. With the peak loads limited to a safe value, it then becomes possible to permit the average load to approach somewhat nearly the continuous capacity of the machine which condition results in load factor betterment. Caution must be exercised, however, not to exceed the limit in this direction since the resistors may be in circuit suffi-

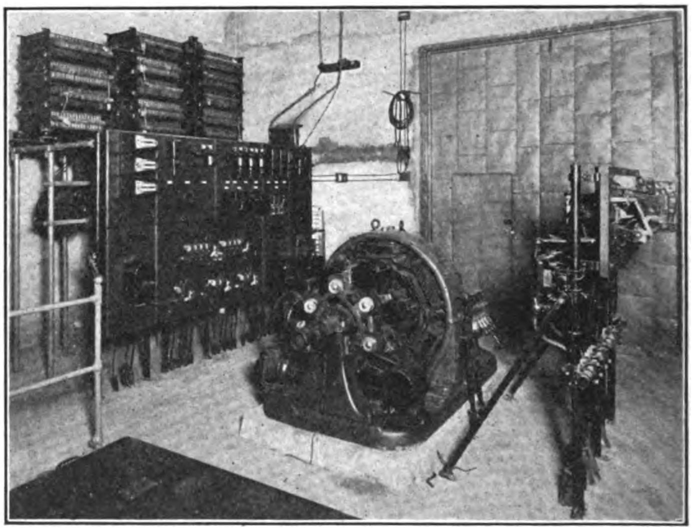

Fig. 5—Interior View of 2000-Kw. 600-Volt Synchronous Converter Substation on Cincinnati Lawrenceburg and Aurora Electric Street Railway

ciently to interfere too greatly with the average trolley voltage, thereby decreasing train speeds as well as incurring an undesirable energy loss from heating in the resistors. Based on this principle as well as the fact that the average heating of transformers is low in the smaller interurban automatic substations due to frequent light-load shut-downs, it has become generally standard practise in these stations to provide transformers having a capacity equal to 80 per

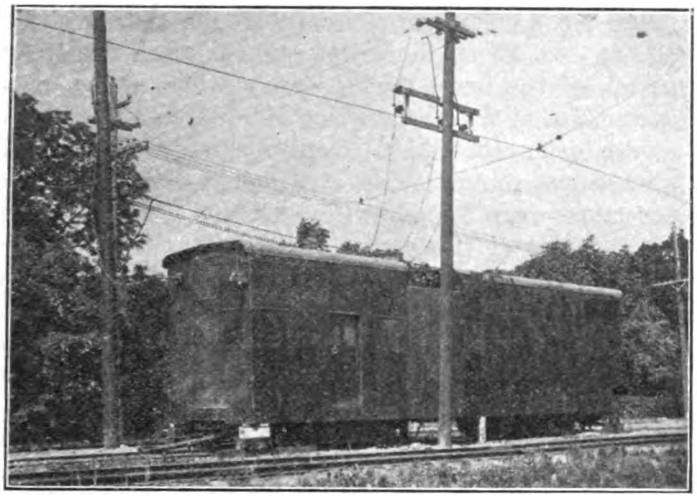

FIG. 6—PORTABLE AUTOMATIC SUBSTATION CONTAINING 500-KW. 600-VOLT SYNCHRONOUS CONVERTER—KANSAS CITY RAILWAYS CO.

cent of the converter rating. In justification of the idea it may be noted that there are in operation at least two railway systems where full advantage of the principle is realized with exceedingly satisfactorily results.

Feeder Saving. Reduction in feeder copper is effected by the application of automatic substation based on the fact that elimination of labor cost in such stations permits a closer spacing and smaller capacity than would be the case with the manually operated type. For the same line characteristics then less feeder copper is required. The installation of automatic stations has in several instances resulted in the removal of sufficient copper to offset materially the cost of the station. Frequently, conditions arise on existing roads when it is necessary to bolster up some particular section of the system due to rapid growth in service requirements. An automatic station is often the cheapest means of producing the desired result since it is more economical to operate than a manual equipment.

Electrolysis. The effects of electrolysis may be to an extent eliminated by the use of automatic substations since their economic spacing is less than those manually operated. Such an arrangement shortens the negative return with a consequent reduction in potential difference between the rail and adjoining water mains. The National Bureau of Standards recognize this benefit in connection with the principle of automatic substation installations.

As previously stated the first automatic installation consisted of devices which with but few exceptions had already been developed by manufacturers for application to other service such as power station, car equipment, steel mill and similar industrial requirements. Experience soon taught, however, that successful automatic substations required an ultra-reliable class of apparatus since the failure of a single device means a shut-down of considerable duration because it necessitates sending a man from some distant point to investigate the trouble. This fact has been realized by the manufacturers and based on experience during recent years a class of apparatus has been developed for these stations which embodies a degree of reliability consistent with the exacting demands of present-day railway service.

Details of Operation. The functions of starting and connecting the machines to the line upon power demand and finally shutting them down after the demand for power has ceased are all carried on in their proper sequence without any assistance whatsoever from an operator. In present day practise the great majority of these stations are controlled entirely by the automatic equipment in accordance with the above statement, but a few are, for specific reasons, remotely controlled by dispatchers with the aid of a pilot wire. A remote controlled station as generally applied may be considered in the same class with a purely automatic station since the control current merely replaces the automatic devices which determine when the station is to start or stop. The remaining apparatus which performs the actual switching operations are identical in both cases.

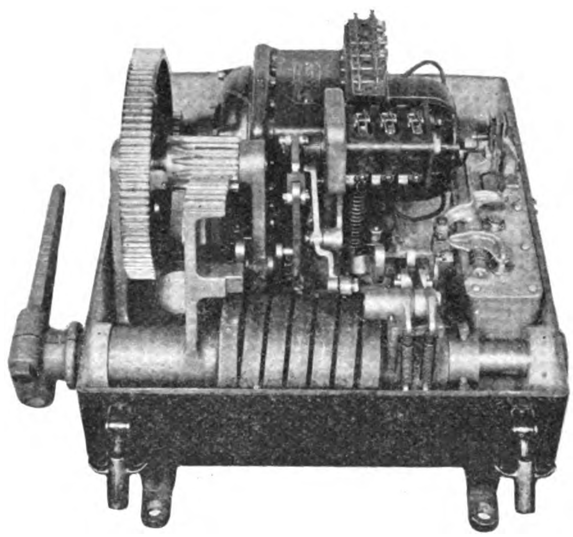

FIG. 7—MOTOR-OPERATED OIL CIRCUIT BREAKER MECHANISM FOR AUTOMATIC SUBSTATIONS

The type of automatic equipments in the most extensive use consists of a group of relays, grid resistors and standard contactors, which together with a motor driven drum controller shown in Fig. 8 perform the usual function of starting, stopping and protecting the machines against irregularities without the aid

of an attendant. In general, relays are used where the functions of starting, stopping and protecting the machines depend upon voltage, current or independent time values. During starting and stopping, however, numerous operations must be performed in a definite sequence, which if not strictly adhered to, is conducive to service interruptions. The motor-driven drum controller is used to obtain this fixed time relation of events and to substitute, wherever possible, a type of contact more substantial than can be used with relays. This device also includes a small d-c. generator which at the proper time during the starting operation separately excites the converter field, thereby definitely and immediately insuring the correct polarity.

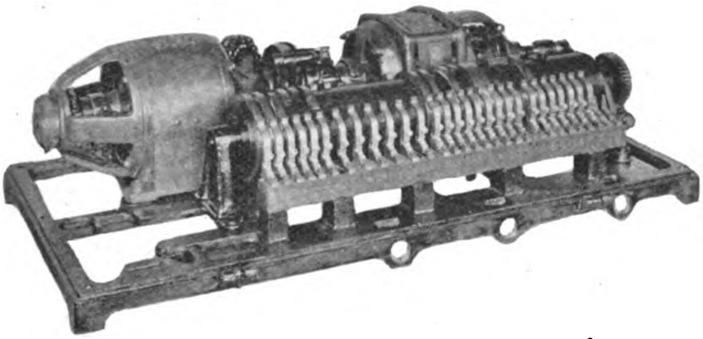

FIG. 8—MOTOR-OPERATED CONTROLLER AND EXCITER FOR AUTOMATIC SUBSTATIONS

Protective devices having the following duties are provided to perform the functions ordinarily left to the discretion of the operator.

1. To limit the overloads.
2. To limit the temperatures.
3. To shut down the machine.
   (a) When a-c. or continuous d-c. short circuits occur.
   (b) Upon failure of alternating current.
   (c) Upon failure of any device.
   (d) In case of excessive speed.
   (e) Upon reversal of direct current.
4. To prevent machine starting.
   (a) During low a-c. voltage.
   (b) During single-phase a-c. supply.

By referring to Fig. 1 which is a typical wiring diagram of an automatic 500-kw., 600-volt equipment, the sequence of operation may be followed. For convenience of reference the principal devices have been numbered or otherwise labeled. It will be noted that the 220-volt a-c. control bus is continuously excited from the control transformer No. 11 and the operating coil of contact-making voltmeter No. 1 is always connected between trolley and ground.

Assuming a particular station is shut down and a train is approaching. As it increases its distance from the next station on the line it will eventually cause the trolley voltage to drop and at a predetermined value, usually 450 volts, contact-making voltmeter No. 1 opens, de-energizing the operating coil of relay No. 2, which had been previously held open by excitation from the 220-volt a-c. control bus through relay No. 1. The closing of No. 2 closes relay No. 3 causing it to pick up and close contactor No. 4 provided the hand reset switch and contacts of a-c. low-voltage relays No. 27 are closed. Relays No. 2 has a dashpot to prevent momentary fluctuation of low voltage from producing false operations of the machine. With the drum controller No. 34 in the "off position" as would be the case before the machine starts, contactor No. 4 completes a circuit through segments No. 13 and No. 16 on the drum controller and the limit switch of the brush-raising device which closes contactor No. 6, thereby starting rotation of the motor-driven drum controller. Controller segment No. 15 soon closes contactor No. 5 which in turn energizes the motor-operated oil switch mechanism causing the main converter transformers to become energized by the closing of oil circuit breaker No. 7. The operating coil connection of contactor No. 5 is then transferred from segment No. 15 to No. 14. This circuit passes through an auxiliary switch on the oil circuit breaker to insure the return of all devices to their normal position should the breaker open for any reason. When segment No. 2 makes contact, starting contactor No. 10 is closed connecting the converter to the low-voltage taps provided the a-c. supply is delivering three-phase current as determined by relay No. 32. Shortly the drum controller stops rotating because of the gap in segment No. 16 and waits if necessary for the converter to come up to speed. At approximately synchronism, speed-control switch No. 13 closes, bridging by aid of segment No. 20 the gap in segment No. 16, causing the controller again to start rotating so as to complete the function of connecting the machine to the line.

Next segment No. 3 closes contactor No. 31 connecting to the converter fields a 250-volt supply obtained from the small generator on the drum controller, thereby immediately ensuring proper polarity. Contactor No. 31 is then opened by segment No. 3 and the self-exciting field contactor No. 14 closed by segment No. 4 and running contactor No. 16 closed by segment No. 5 connecting the converter to normal secondary a-c. voltage. Starting and running contactors No. 10 and No. 16 are both mechanically and electrically interlocked with respect to one another to insure against accidentally short-circuiting a portion of the transformer secondary winding. Segment No. 26 next starts the motor-operated brush rigging causing the converter brushes to be lowered which completes the operation of preparing the machine for connection to the d-c. bus. Segment No. 7 is next energized with 600 volts direct current and shortly thereafter segment No. 8 closes the d-c. line contactor No. 18 whose control circuit is in series with converter field relay No. 30, polarized relay No. 36 and auxiliary switches on running contactor No. 16 and control

contactor No. 4, thereby ensuring before closing No. 18 that the converter has proper polarity, correct field and full voltage a-c. running connections.

As soon as the line contactor closes the machine delivers load to the bus through the load limiting resistors which, however, are soon short-circuited by contactors No. 20 and No. 21 operated by segments No. 9 and No. 10. The drum controller is then stopped by segment No. 17. When connection to the bus is made through No. 18 the flow of current closes relay No. 37, which will cause relay No. 3 to remain closed regardless of relay No. 1 whose function started the station. In other words the control of the station is now dependent on the contacts of No. 37 which will remain closed so long as a predetermined current is being delivered to the bus. Should the current fall below a set value, relay No. 37 will open and cause relay No. 3 to drop out after a certain period of time and shut down the station. Relay No. 3 has a dash-pot and is timed so that momentary low values of current causing No. 37 to open will not shut down the equipment.

When the station does shut down relay No. 3 opens contactor No. 4 causing running contactor No. 16 and d-c. line contactor No. 18 to drop out and disconnect the machine. Contactor No. 5 opens after contactor No. 4 which operation establishes through an auxiliary contact a circuit to contactor No. 6, thereby starting the controller and running it to its "off position." While doing this, however, segment No. 24 trips out the oil circuit breaker and segment No. 25 causes the converter brushes to be raised in preparation for starting upon the next load demand.

The proceeding covers briefly the necessary operations in starting and stopping the machines, but there remains the equally important functions of protecting the equipment from irregularities caused by disturbances on either the a-c. or d-c. side of the station or within the apparatus itself. Briefly these contingencies are taken care of as follows:

In the event a heavy d-c. overload occurs, relay No. 24 will pick up and open contactor No. 20, thereby inserting resistance in the circuit. Should the overload increase to a greater value, relay No. 25 will operate and insert more resistance, and in stations not provided with individual feeder protection a third step of resistance is provided to limit still greater overload demands. The value of resistance used is such as to permit short circuit in the immediate vicinity of the station without injuring the machine. The resistor capacity, which determines the length of time heavy overloads can be carried by the resistors without serious heating, is to a degree a function of the service requirements but the duration of those irregularities cannot be foretold with accuracy and the practise of providing liberal capacity in the resistors has not only proved desirable but very necessary. In some stations individual feeder protection which consists of an overload relay No. 23, a contactor No. 19 and a resistor in each feeder circuit is installed, thereby localizing to a degree the function of overload protection to each feeder. With such an arrangement only two sections of resistance are used in the machine circuit.

Protection from overheating the machine, its bearings and load limiting resistors is obtained by use of temperature relays No. 38 and No. 33 arranged to shut down the station immediately should such a condition arise.

A reversal of direct current is prevented by relay No. 29 and over-speed by speed-limit switch No. 12-A. Both of these devices necessarily operate a control circuit which immediately opens contactor No. 4 and shuts down the station. A shunt-trip hand-operated d-c. circuit breaker No. 15 is in series with No. 18 and only used to protect against the possibility of the line contactor freezing closed. Should this condition occur the converter would motor from the d-c. end upon the a-c. end being disconnected and the excessive speed resulting would trip the circuit breaker No. 15 through the operation of speed switch No. 12.

In case a short circuit occurs on the a-c. side of the equipment, the definite time limit overload relay No. 28 will trip out the main oil circuit breaker, shutting down the station and at the same time opening the hand reset switch which necessitates reclosing by hand before the station can be started again. This feature insures an inspector visiting the station to investigate the cause of the serious a-c. overload.

Low a-c. voltage relay No. 27 which is calibrated for a definite value is connected so as not to permit the station to start or to shut it down if running should the high tension voltage become so low as to interfere with proper operation.

If for any reason a single-phase condition exists on the secondary side of the transformer during starting operations, relay No. 32 will lock out starting contactor No. 10 and prevent the converter from being connected to the transformer.

Polarized relay No. 36 protects against the possibility of the machine ever being connected to the line in the reverse direction. Unless proper polarity has been established before connecting the machine to the bus, line contactor No. 18 will not close.

In stations containing a motor-generator set instead of a synchronous converter, certain modifications to the equipment are necessary to accommodate the starting operations, but the scheme of operation with few exceptions is similar to the converter equipments. Oil-immersed starting and running contactors are used because of the higher transformer secondary voltage and a certain amount of overload protection is obtained by inserting one or two steps of resistance in the generator field circuit in addition to two steps of series resistance in the main d-c. circuit. This arrangement reduces initial cost since the field resist-

ance and its contactors are of small capacity. An energy saving in resistor heat loss is also accomplished. The 250-volt generator on the drum controller becomes unnecessary in the case of a motor-generator automatic equipment.

The recent development of flash barriers for railway machines affords a device of much benefit to automatic substations and these devices are now included by one manufacturer as a regular part of the equipment. Where conditions are particularly severe and much trouble is experienced from flashing, barriers and a quick-acting circuit breaker will absolutely protect the machine.

The recent development in automatic equipments has largely consisted of perfecting and making more reliable the present type of station as well as arranging for and applying the principle in other applications such as lighting, mining and hydraulic generating stations. Among specific instances of improved design may be mentioned the elimination from the equipment of all disk-type interlocks and the substitution of substantial finger-type auxiliary contacts. Relay contacts element have been improved where necessary so as to provide a quick make and break action and on d-c. circuits blow-out coils have been added. An improved type of motor-operating mechanism as shown in Fig. 7 for oil circuit breakers is now in use in which compactness and reliability are the outstanding features. D-c. contactors having a rupturing capacity sufficient to handle any load conditions have been developed and are performing their function with complete success. Reverse current and under-load relays of substantial construction and capable of accurate calibration at low current values have been designed to accommodate the conditions of automatic substation operation.

The use of automatic control in railway substation has in a comparatively short time expanded to where it is firmly established in city and interurban railway operation. The successful experience of the past has resulted in larger capacity stations serving heavy traffic being made automatic. The adaptation of this type of control to electric trunk line service at 2400 or 3000 volts direct current as well as more extended use in the strictly industrial field is not far beyond the horizon.

Short-Circuit Protection for Direct-Current Sub-Stations

BY J. J. LINEBAUGH

Railway and Traction Engineering Dept., General Electric Co., Schenectady, N. Y.

The author includes an outline of the progress made in protection of direct-current machinery from short circuits since the publication of a paper at Atlantic City on this subject.

The improvements mentioned include the refinement and perfection in details of the flash barriers; a new design of high-speed circuit breaker for both direct-current substations and electric locomotives; a new high reluctance commutating pole for 60-cycle synchronous converters and a new design of protected brush holder. An instructive analysis of conditions during direct-current short circuits is shown by several photographs, oscillographs and diagrams. Special reference is made to operating results on the electric zone of the Chicago, Milwaukee and St. Paul Railroad.

THE investigation of means to prevent flashing of direct-current machinery and development of suitable equipment has been continued since the presentation of the paper on "Protection from Flashing for Direct-Current Apparatus," by Mr. J. L. Burnham and the writer at the Atlantic City Convention in 1918.* This paper outlined in a general way the results obtained with quite a number of different methods of reducing or preventing flashing under extreme overload or short-circuit conditions.

This study indicated that a special form of flash barrier with arc coolers and a new form of high-speed breaker with current-limiting resistance had proved the most promising development. Tests showed that the two types of protection provided complete protection from a "dead" short circuit caused by short-circuiting the terminals of a machine without external resistance.

These two types of protection have been further perfected and are now in regular commercial use. They are used either separately or together and in many instances considered standard railway practise.

The improved type of high-speed breaker described has been perfected in all details as shown in Figs. 1 and 2.

Thirteen of these breakers were installed by the Chicago, Milwaukee & St. Paul Railroad as part of the electrification of their Coast and Cascade Divisions. Fig. 2 shows the breaker with the arc chute installed but with covers removed. This view shows the calibrating rheostat used to set tripping point of the breaker. Description of this breaker will not be repeated as general theory of operation and design is described in the paper referred to, and more detailed description of the perfected breaker will be described in article by Mr. J. F. Tritle in the April number of the *General Electric Review*.

*TRANS. XXXVII Part II, 1919, page 1341-1365.

To be presented at Pittsburgh Meeting of the A. I. E. E., March 12, 1920.

This breaker was used instead of the first type of circuit breaker which has given successful operation during the past three years in the fourteen substations of the 440-mile original electrification of the Chicago, Milwaukee & St. Paul Railroad. This new breaker has the advantage of lower cost and greater simplicity.

One of these breakers is used with each of the 2000-kw., 3000-volt, synchronous motor-generator sets in the Tacoma, Renton, Cedar Falls, Hyak and CleElum Substations and the remaining five breakers on each of the new gearless type passenger locomotives. On account of the lower cost of these breakers and advantages of using the "unit" system throughout, each of the sets is protected by its own high-speed breaker instead of one breaker per substation, the arrangement in the original installation.

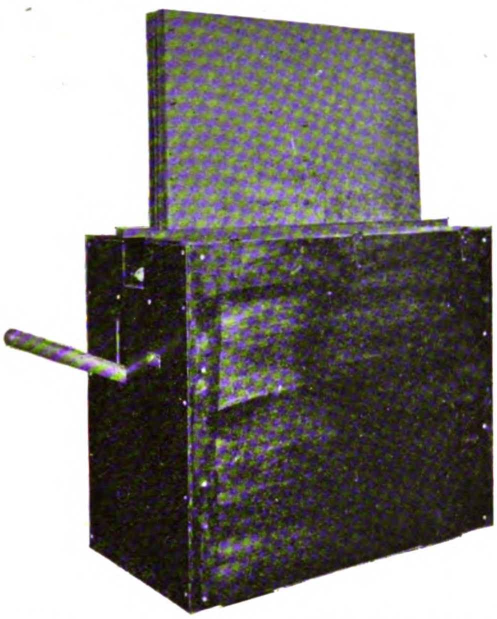

Fig. 1—1500-Ampere, 3000-Volt, D-C. High-Speed Circuit Breaker

The general connections, location of circuit breaker, etc., are shown in Fig. 3.

The circuit breakers for the substations and locomotives are exactly alike with exception of interlocking and calibration for tripping points.

The circuit breakers were given a very exhaustive test in connection with one of the 2000-kw. sets in test before shipment, with very successful operation in all details. It was found that the generators could be short-circuited with only sufficient cable in the circuit to connect the different meter shunts, short-circuiting contactor and high-speed breaker without damaging machine in any way and with practically no flashing at the brushes. Figs. 4 and 5 show photographs of two of these short circuits, one of which gave so slight a flash that it can hardly be seen while the other shows very slight flashing in the flash barriers. Fig. 6 shows oscillogram of one of these short circuits giving a very good idea of the high speed of the breaker and the protection afforded. It will be noted that the current was limited to about 7000 amperes and reduced to three times load in 0.016

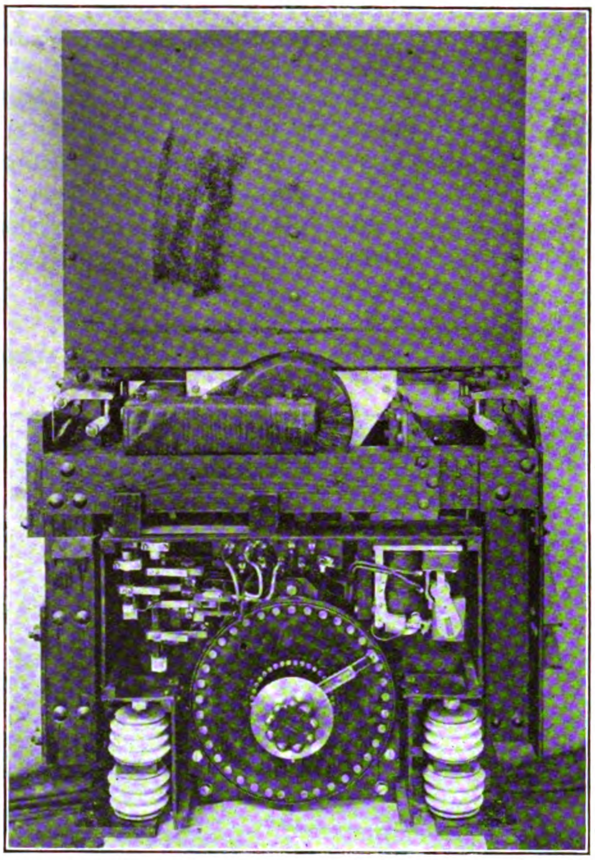

Fig. 2—1500-Ampere, 3000-Volt D-C. High-Speed Circuit Breaker With Asbestos Lumber Casing Removed Showing Rheostat Used to Obtain Different Tripping Points

seconds. The current starts to decrease in 0.0081 of a second and it will be noted that the area representing the load which would be likely to cause flash-over is very small and of such short duration that

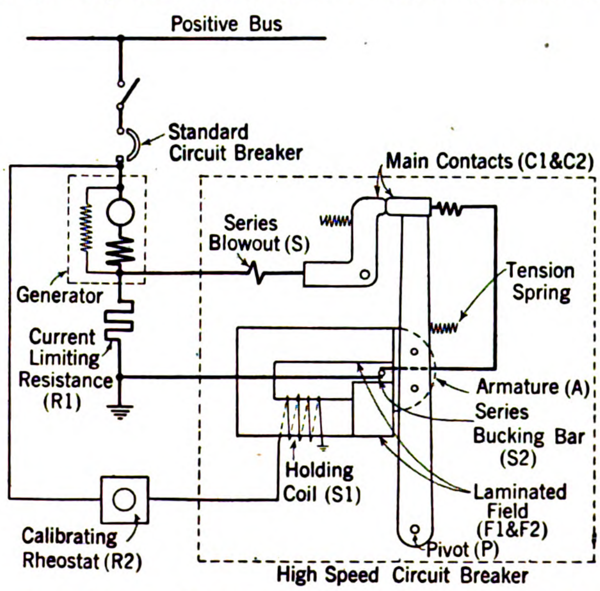

Fig. 3—General Connections of High-Speed Circuit Breaker

very little gas or arc could be formed. Fig. 7 has been prepared to show graphically the much greater protection afforded by circuit breaker of such high speed over that obtained with the usual type of breaker. This figure shows the current curve of a 2000-kw., 3000-volt machine on short circuit when protected by the high-speed breaker and by a standard 3000-volt breaker designed for higher speed than usually obtained with regular carbon-break 600-volt breakers. The area of each curve above the load which would cause flashing has been cross-hatched to show the ratio between the two areas which gives a very good idea of the value of the great speed and the reason there is so little flashing. During these tests about one photograph out of four was similar

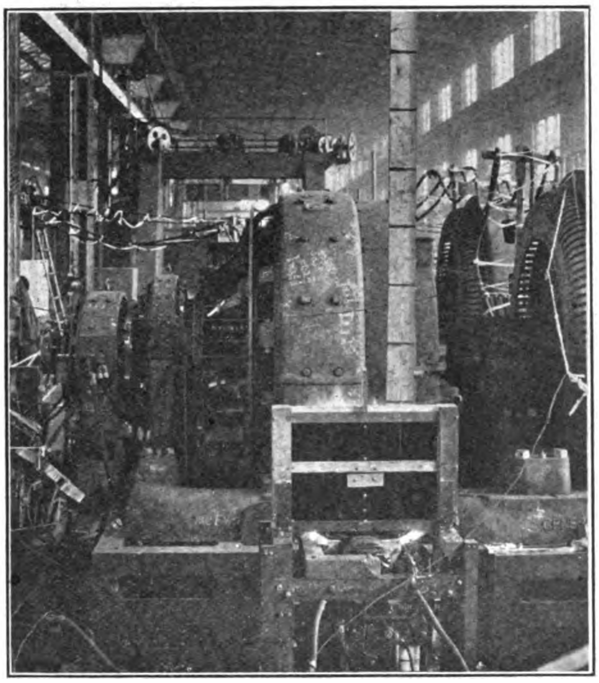

Fig. 4—Short Circuit on 2000-Kw., 3000-Volt Motor-Generator Set Protected by High-Speed Circuit Breaker and Flash Barriers. Tripping Point 2550 Amperes. Line Resistance 0. Current Limiting Resistance 1.2 Ohms

to Fig. 4, while the others were of the character shown in Fig. 5.

A special reliability or endurance test was made as part of the acceptance tests of the breaker during which about 65 short circuits of different magnitude, fifteen of which were "dead" short circuits, were applied at intervals of about 2½ minutes without cleaning the commutators or giving them any attention whatever. At the conclusion of these tests, five "dead" short circuits were thrown on the set within ten minutes. At the end of these tests, commutators were in excellent condition without any need of cleaning or attention of any kind.

These circuit breakers are now in regular operation and reports received of their operation have been very gratifying.

The application of the high-speed circuit breaker to direct-current electric locomotives is another distinct advance as in addition to protecting the apparatus on the locomotive, it prevents the short circuits from affecting the substations.

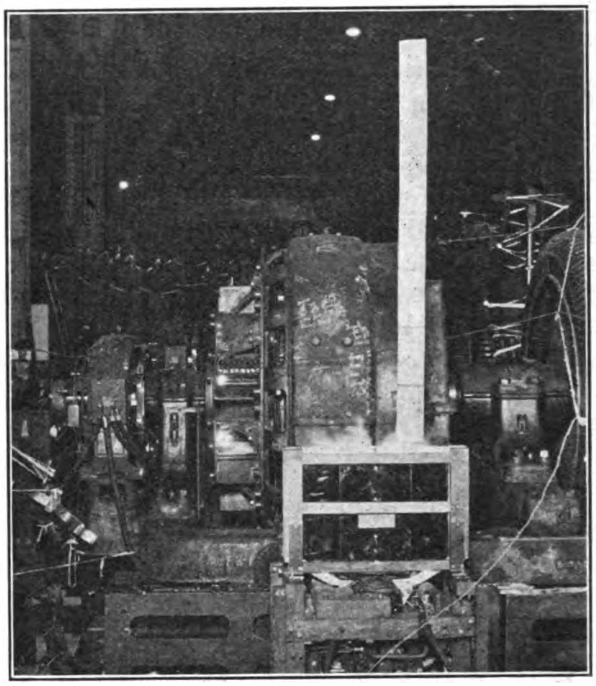

Fig. 5—Short Circuit on 2000-Kw., 3000-Volt Motor-Generator Set Protected by High-Speed Circuit Breaker and Flash Barriers. Tripping Point 2940 Amperes. Line Resistance 0. Current Limiting Resistance 1.2 Ohms

If both the substations and locomotives are equipped with this type of high-speed circuit breaker, current under maximum conditions would never reach a value much greater than 7000 amperes. The value of the

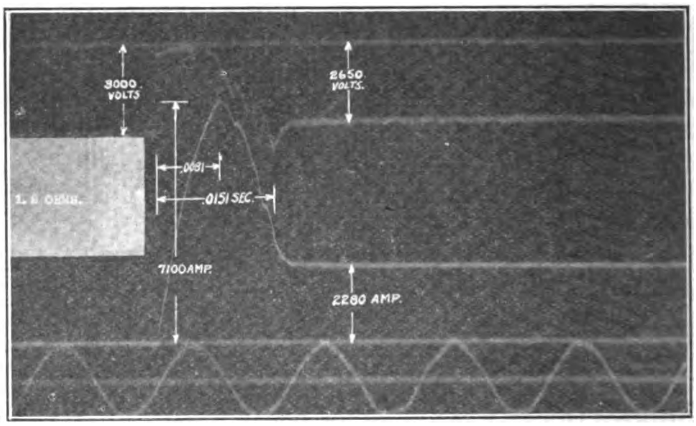

Fig. 6—Short Circuit on 2000-Kw., 3000 Volt Motor-Generator Set Protected by High-Speed Circuit Breaker and Flash Barriers. Tripping Point 2250 Amperes

maximum short-circuit current decreases very rapidly with distance from substation as shown in Fig. 8. These records were taken with a 1500-kw., 3000-volt motor generator set connecting the overhead trolley consisting of two No. 4/0 wires directly to the 100-

lb. track rails and closing the circuit at the substation. It will be noted that the maximum peak current is only 3600 amperes with short circuit 4800 ft. from the substation and 2860 amperes, 9600 ft. from the substation as compared with 7000 amperes "dead" short circuit across the terminals of the machine.

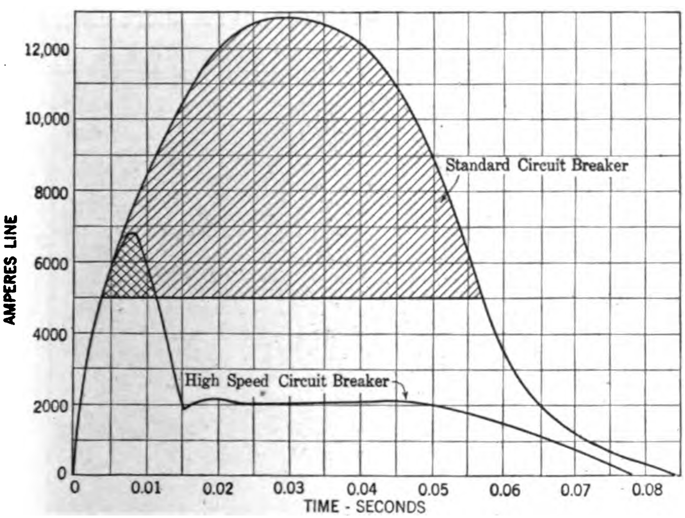

Fig. 7—Short Circuit on 2000-Kw., 3000-Volt Motor-Generator Set Protected by High-Speed Circuit Breaker with Curve Showing Current Which Would be Obtained with Standard Circuit Breaker. Ratio of the Area of the Two Curves Above 5000 Amperes Gives Indication of the Protection Afforded

The value of this type of protection was proved very conclusively during these tests due to the accidental grounding of one of the switchboard busbar insulators. The high-speed breaker inserted the current limiting resistance so quickly that some time was required to locate the trouble as burning at the grounded point was so slight as to be hardly noticeable, indicating that even under such extreme conditions current is reduced so quickly that sufficient time is not allowed to cause current to generate sufficient heat to cause destruction of the current-carrying parts.

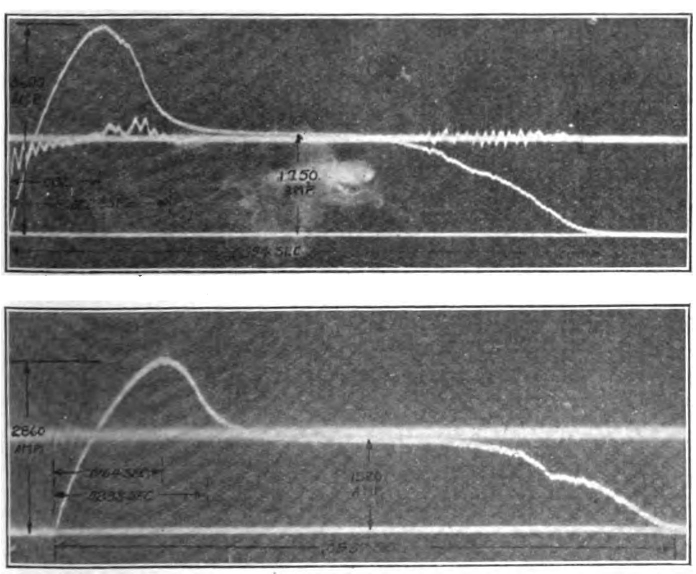

Fig. 8—Short Circuit on 1500-Kw. 3000-Volt Motor-Generator Set at Different Distances from Substation. Generators Protected by High-Speed Circuit Breaker and Flash Barriers

Another of the incidental advantages of this type of protection is the elimination of disturbances on the a-c. side of synchronous converters or motor-generator sets ordinarily caused by d-c. short circuits due to the fact that the load is decreased so quickly that momentum of the armatures supplies the energy and the load is not increased materially on the a-c. side. The overload relays are therefore not affected, increasing very greatly the general operating efficiency of a substation, eliminating time required to start up set from the a-c. side, etc. After the occurrence of a short circuit it is only necessary for the operator to close the high-speed breaker and then the main switchboard breaker which is interlocked with the high-speed breaker after which the main switch is thrown in following regular switching practise. If the short circuit still persists, the high-speed breaker will again open but with no flashing or damage to brushes or commutator and greatly decreased duty on the regular breaker.

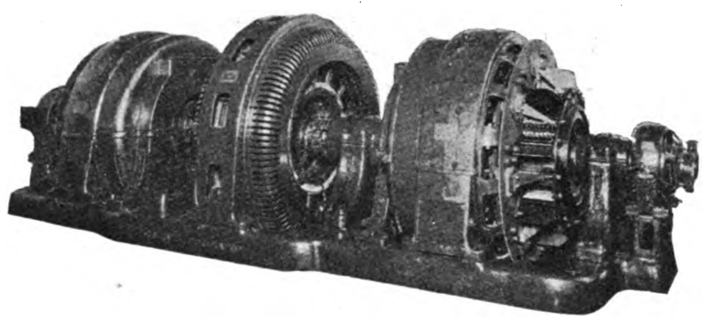

Fig. 9—2000-Kw., 3000-Volt D-C. Synchronous Motor-Generator Set Equipped with Flash Barriers

The flash barriers described in the original paper have not been changed in any essential details, improvements being along the line of simpler construction, ease of removal for inspection and improvement in appearance.

These barriers with iron wire arc coolers are standard equipment on all 3000-volt motor-generator sets as well as on all machines used in connection with automatic substation control. Fig. 9 shows one of the 2000-kw., 3000-volt sets for the Milwaukee electrification equipped with these barriers, while Fig. 10 shows barriers for 600-1200-volt, 60-cycle, 500-kw. synchronous converter.

Flash barriers and high-speed circuit breaker are standard equipment on 1500 to 3000-volt substations and it is believed this practise will be extended to include 600 and 1200-volt apparatus.

Another advance in short-circuit protection is the protected type of brush holder recently perfected as

shown in Fig. 11. This brush rigging is protected on all sides where flashing might occur by asbestos lumber so that an arc cannot readily hold between brush holders of opposite polarity and prevents the formation of iron or copper vapor which might cause a flash to the frame and cause damage to the brush rigging or commutator. A removable cover is provided for inspection and removal of brushes. It is made of an iron sheet for convenience as there has been no tendency for the arc to strike this part of the brush rigging during tests or in actual operation. It will be noted that this type of brush rigging lends itself very readily to the addition of flash barriers as shown in Fig. 10.

This type of brush rigging has been standardized for all 600-volt, 60-cycle synchronous converters.

The use of the high reluctance commutating pole is a very promising improvement which has just been made in 60-cycle, 600-volt synchronous converters

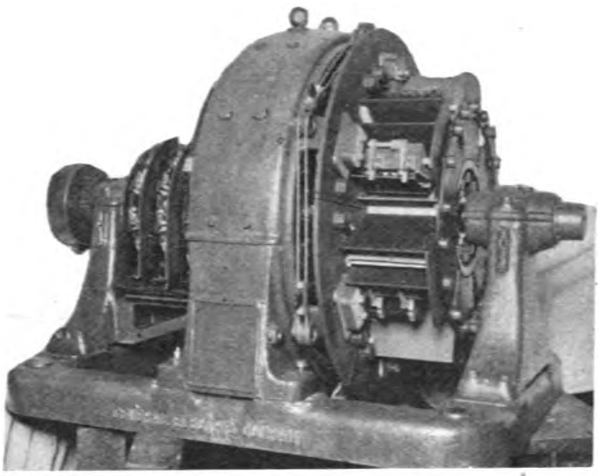

Fig. 10—500-Kw., 600 1200-Volt 60-Cycle Synchronous Converter Equipped with Flash Barriers

and has been standardized for all 60-cycle machines. Tests indicate that the use of these poles raises the flashing point at least 50 per cent. In actual commercial use the improvement is greater than indicated by this figure as a very great proportion of short circuits which originally caused flash-over would not cause flashing on machine equipped with this new type of commutating pole winding.

These improvements are of particular value for 60-cycle converters which are inherently more sensitive than 25-cycle converters.

Brief attention should be called to the great protection afforded by tapping the feeder at some distance from the substation. This is undoubtedly the cheapest type of protection which can be used but cannot be relied upon to prevent flashing over under extreme short circuits. A very slight amount of permanent resistance such as would be given by such an arrangement greatly reduces the number of flash-overs with very little loss of energy or voltage. Under ordinary conditions it is believed that the distance to the first tap need not be greater than 2000 ft. A greater distance than this causes an appreciable loss of energy and drop in voltage. Fig. 12 shows very clearly the great benefit of a small amount of resistance in reducing the maximum possible current on a short circuit.

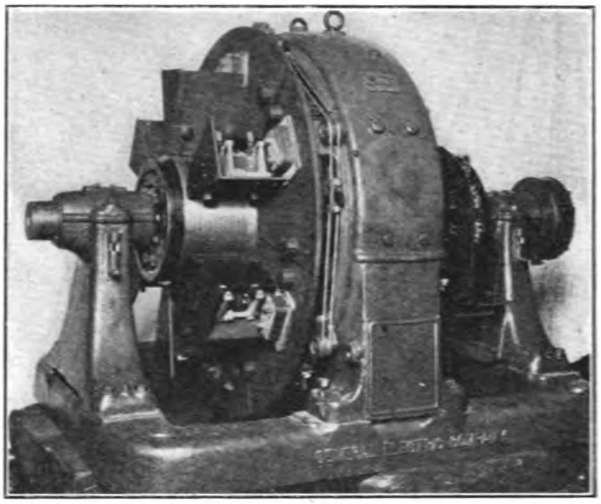

Fig. 11—500-Kw., 600 1200-Volt 60-Cycle Synchronous Converter with Protected Type of Brush Holder

If complete immunity is desired from short circuits, the high-speed circuit breaker and barriers undoubtedly offer the best known solution. With this protection, feeder taps can be connected to the overhead trolley directly at the substations, reducing losses to a minimum. Maintenance on the substation apparatus will also be decreased as burning from short circuits undoubtedly causes most of the wear and deterioration on brushes and commutator. Another particular advantage of this type of protection is that it can be applied to old generators or synchronous converters of any voltage without change in the machine itself.

Subscription. $10.00 per year to United States, Mexico, Cuba, Porto Rico, Hawaii and the Philippines; $11.00 to Canada and $12.00 to all other countries. Single copies $1.00. Volumes begin with the January issue.

Changes of advertising copy should reach this office by the 15th of the month for the issue of the following month.

INSTITUTE MEETING AT PITTSBURGH

MARCH 12, 1920

On Friday March 12, 1920 the American Institute of Electrical Engineers will hold its 358th Meeting under the auspices, jointly, of the Pittsburgh Section and the Traction and Transportation Committee. The headquarters for the meeting will be the William Penn Hotel. The Board of Directors and the various committees will hold their sessions in the morning. The Board will meet at the Duquesne Club where luncheon will be served. During the morning there will be offered the opportunity to take an inspection trip through the Westinghouse Works concluding with a luncheon to be served to all as guests of the Company. Technical sessions will be held in the afternoon and evening. A subscription dinner will be served in the Ball Room of the William Penn Hotel at 6:15 p. m.

Technical Sessions

2:30 p. m.—Ball Room, William Penn Hotel

1. *Short-Circuit Protection for D-C. Substations* by J. J. Linebaugh, General Electric Company.
2. *Flashing of 60-Cycle Synchronous Converters and Some Suggested Remedies* by Marvin W. Smith, Westinghouse Electric and Manufacturing Co.
3. *Automatic Railway Substations* by Frank W. Peters, General Electric Company.
4. *Automatic Substations for Heavy City-Service* by R. J. Wensley, Westinghouse Electric and Manufacturing Co.

8:00 p. m.—Ball Room, William Penn Hotel

5. *The Two Designs for the Chicago, Milwaukee and St. Paul Locomotives* by W. O. Batchelder, General Electric Company and by N. W. Storer, Westinghouse Electric and Manufacturing Company.

Inspection Trip

On Friday morning there has been arranged an inspection trip through the Works of the Westinghouse Electric and Manufacturing Company at East Pittsburgh. This trip will offer an opportunity to view the new electric locomotives of the Chicago, Milwaukee and St. Paul. Luncheon will be served in the new Cafeteria, said to be the largest in the world, and all are invited to be the guests of the Company.

Train leaves Penn Station, Pittsburgh, at 9:15 a. m. and East Liberty Station at 9:28 a. m. Members from the East, leaving New York Thursday night at 11:30 p. m. should get off at East Pittsburgh. The trip through the Works will start at 10 a. m. and guides will be provided at main entrance to General Office.

Dinner

A subscription dinner will be served in the Ball Room of the William Penn Hotel at 6:15 p. m.

FUTURE A. I. E. E. MEETINGS

Boston, April 9, 1920.—The Boston meeting of the Institute will be held jointly with the American Electrochemical Society and will be under the auspices of the Boston Section and the Committee on Electrochemistry and Electrometallurgy. Tentative plans have been arranged as follows: On Thursday, April 8, the American Electrochemical Society will hold meetings, morning and afternoon at M. I. T., and members of the Institute are cordially invited to attend. On Thursday evening at 8:30 p. m. a Get-together Smoker is planned by the A. E. C. S. at the Copley Plaza Hotel to which all Institute members are invited. On Friday, April 9, a joint session will be held at 9:30 a. m. for the presentation and discussion of a symposium "Electrically Produced Alloys." In the afternoon an inspection trip will be made to the laboratories of the General Electric Company at Lynn where talks on research work at the laboratories will be delivered by Professor Elihu Thompson and others. At 6:30 p. m. a Subscription Dinner will be served at the Copley Plaza at $4.00 per plate. At 8:30 p. m. the evening session will be held at the Copley Plaza where a symposium will be presented on "Power for Electrochemical Purposes." The A. E. C. S. will continue its meetings on Saturday. The plans outlined are subject to change and the final program will be published in the April JOURNAL.

New York, May 21, 1920—Annual business meeting of the Institute. Details to be announced later.

Annual Convention, June 29-July 2. In accordance with the action of the Board of Directors at a meeting held February 18th, and negotiations carried on since, it has been decided to hold the Annual Convention of the Institute at The Greenbrier, White Sulphur Springs, West Virginia, June 29-July 2. This is a week later than it was originally planned to hold the Convention. Details will be announced later.

Pacific Coast Convention, Portland, Ore., July 21-23.—At the meeting of the Board of Directors held February 18th, it was decided, in accordance with the recommendation of Vice-President Fisken and the Portland Section, to hold the 1920 Pacific Coast Convention at Portland, Ore., July 21-23.

Further information will be announced later.

FUTURE SECTION MEETINGS

Cleveland.—March 16, 1920. Subject: "The Vacuum Tube and Some of its Applications." Speaker: Mr. J. W. White, General Electric Company.

April 20, 1920. Subject: "The Sperry Gyroscope." Speaker: Robert B. Lea, Sperry Gyroscope Company.

Schenectady.—March 5, 1920. Subject: "Fly-Wheel Effect for Synchronous Motors Connected to Reciprocating Compressors." Speaker: Mr. R. E. Doherty, A-C. Engg. Dept., General Electric Co., Schenectady, N. Y.

March 19, 1920. Subject: "Power and Transmission." Speaker: Mr. H. H. Dewey, P. & M. Engg. Dept., General Electric Company, Schenectady, N. Y.

PROPOSED FEDERATION OF ENGINEERING PROFESSION

BY CALVERT TOWNLEY

President American Institute of Electrical Engineers

At Lake Placid in June when after full discussion and some amendments you endorsed the report of your Development Committee you took a step of far reaching importance, the effect of which it is difficult to now predict. I refer particularly to that part of the report which deals with the desirability of greater participation in public affairs by the engineer and which recommends that the Institute cooperate with other engineering bodies in an effort to bring this about.

As you have already been advised in the pages of the JOURNAL in compliance with the Convention's desire, your Board of Directors authorized the Development Committee to appoint delegates to a joint conference on this subject with the other Founder Societies and thereupon, throughout the summer, while most organized engineering activities were suspended, your conferees have held frequent meetings with the conferees of the other Societies. Their report was submitted to your Board for the first time at its August meeting and was printed in the PROCEEDINGS. In November your Directors approved the recommendations in this report and instructed your conferees to join with the conferees of such other Societies as might similarly approve the report, in putting into effect the plan there outlined. The report has now been similarly approved by two of the other Societies and therefore the joint conferees are now getting ready to start. Without unnecessary loss of time in all likelihood invitations will be issued to a large number of engineering organizations, both national and local, to send delegates to a meeting at some central point for the purpose of creating a vehicle by which the engineers of the country can unite to consider and to act upon matters of common concern.

When the constitution of the American Institute of Electrical Engineers was adopted its objects were well set forth to be "the advancement of the theory and practise of electrical engineering and of the allied arts and sciences and the maintainence of a high professional standing among its members." It was further wisely provided "that among the means to this end shall be the holding of meetings for the reading and discussion of professional papers, etc." It will be noted that the constitution says "*among* the means provided." It does not say the holding of meetings, and the reading of papers should be the only means employed although for good and sufficient reasons that was practically the only means adopted until a comparatively recent date. When Engineering Council was organized in 1917, a radical move was made. An entirely new activity was started. Council was given broad powers which enabled it to act on matters of common concern without the approval of its sponsors. By participating in the creation of this body the Institute took a long step forward and adopted another means for advancing the theory and practise of electrical engineering and of the allied arts and sciences. But this step, important as it turned out to be, was the act only of your Board of Directors. The members generally did not pass upon it. They knew comparatively little about it. Subsequent events have raised a doubt as to whether even some of the Directors who supported the plan fully understood the extent to which they were delegating authority—much less foresaw how the force of circumstances would oblige Engineering Council to take so active a part in the affairs of the city, state and nation. It is therefore most interesting, not to say extremely gratifying, to those who did sponsor Engineering Council that the membership at large has now very definitely expressed the view not only that this movement should be continued but that it should be expanded far beyond anything previously contemplated.

Presented at the Midwinter Convention of A. I. E. E. New York. February 18, 1920.

It would be premature, not to say hazardous, to say now that if and when delegates from a large number of Societies come together, they will organize and their sponsors will support a Federation such as has been proposed by the Joint Conference Committee but at least the National Societies will have done their duties and if the plan should carry it will place in the hands of a democratic body of engineers chosen from engineering organizations of every kind all over the United States a large measure of authority and responsibility to speak for the engineering profession and to take united action on matters of common concern. It is because of the far reaching character of this prospective step that I have chosen to speak to you about it tonight.

I regard it as one of the most important organization matters which are today before the engineers of the country.

Now if this new national body be created to deal with "matters of common concern," what are they? What are the matters of common concern which engineers in general can deal with better than can our own Institute? Obviously they are not electrical questions—equally obviously they are not questions which specifically and solely concern any one of the other technical branches of the engineering so well cared for by the other national bodies. No one wants, and no one has proposed to interfere in any way with the technical activities or other ordinary proceedings of all the various Societies now existing. The words "Common Concern" are well chosen but they do not convey a definite picture. It is easy but dangerous to deal in generalities, therefore perhaps the best way to indicate the kind of things which a national organization could properly do is to recall some of the things which Engineering Council already has done.

Council was organized during the war and its first activity was to help the Government to find engineers suitable for the many different tasks for which they were sorely needed. The demand was not for engineers of any one branch of the profession. Men were wanted from all branches and the Government had inadequate means of finding them or when found of knowing their qualifications. Engineering Council was peculiarly well equipped to do both these things, and it did them with credit to itself and to the profession, for the country's good and to the satisfaction of the authorities.

Another war activity was likewise cooperation with the Government. This time through the medium of a large Committee which helped pass on the merits on the enormous number of devices, processes, methods and inventions—all of them new and untried, the advocate of each of which was more or less sure that its adoption would settle the contest. It was a sifting committee.

Since the Armistice Council has coordinated and expanded the employment bureau maintained over a period of years by some of the Founder Societies, each dealing with its own members only; as a result of which a larger number of engineers have been placed in positions and a corresponding number of employers served. The Council has conducted and is still conducting an exhaustive examination into the classification and compensation of engineers in Government service—and I do not think it is too optimistic to expect that the Government service will be improved thereby and many much needed adjustments brought about.

Many states have passed and other states are considering the passage of legislation requiring all engineers practising within their borders to be licensed. Engineering Council has been diligently at work collecting and compiling all available data on this material and endeavoring to prepare a uniform law which they might feel justified in recommending wherever such legis-

lation was to be considered. It is not believed that engineers in general are in favor of being licensed, but that is not the question. They already have been licensed in some states, are about to be licensed in others whether they will or no and of course it would be far better to be licensed under a uniform and equitable law with clear definitions, reasonable privileges and no undue burdens than to take whatever may come, which is liable to be more or less of the hit and miss variety.

Engineering Council cooperated with the United States Chamber of Commerce by presenting certain fundamental data on the question of water power and was thanked by that organization for its assistance. In fact, Council's presentation was adopted by a Special Committee of the Chamber, was reprinted and sent verbatim to all the local Chambers in the referendum which the national organization took on this subject. Inasmuch as many of the Chamber's recommendations were embodied in the water power legislation which has now pa sed both the House and the Senate, engineers may feel with satisfaction that at least they contributed toward a useful change in these laws which should have a most beneficial effect.

Engineering Council has testified before Federal authorities on many different subjects, always endeavoring to confine itself to matters which deal with fundamental engineering facts which are beyond the field of controversy and to keep away from political and other questions about which differences of opinion exist among its constituents.

The things that I have enumerated are illustrations. They are by no means intended to include everything that Engineering Council has done. They are each and every one useful acts, acts which could and should be done by engineers but which no one Society could do alone and for which therefore a national body speaking for a united profession is very essential. It will be noted that very few matters have been continued activities. They were done once and then attention was directed to something else. In the nature of the case this must always be largely so and therefore the necessity of putting strong men into office of the National Engineering body, men on whose judgment engineers can rely and who may be counted upon to have the courage of their convictions both to act when necessary and to refuse to act the great many more times when matters beyond the purview of their organization are proposed. Therefore also the necessity for authority to act without reference to the supporting bodies for approval.

One of the fundamental features of the plan prepared by your Development Committee and which also appears in that adopted by the Joint Conferees is that the new national organization shall be composed of delegates from existing engineerng bodies. It will not be a new Society composed of individual members. Such a plan was given exhaustive consideration by the conferees and in the end decisively rejected. The rejected plan has not been without its advocates. They urged with much sincerity and not without reason that it would be a very fine thing if all the engineers of the country—perhaps a quarter of a million strong—could unite in one great big organization to deal with non-technical matters, public affairs and, to look after the engineers' human interest. As this was a fundamental question on which a decision had to be made at the very start and before any other steps could be taken and as it was very thoroughly debated both in your Development Committee and by the Joint Conferees, the membership at large should know the arguments pro and con and form their own opinions; therefore I feel justified in dealing with it tonight.

I am fond of quoting Prof. George Swain's comparison of the Engineer and the Idealist because he has stated an important truth more clearly than I have ever heard it stated before. The Engineer, says Swain, approaches a problem with an open mind. He first obtains all the facts available, then bases his conclusions thereon and proceeds to act accordingly. The idealist on the contrary first pictures the ideal result which he would like to achieve and then pursues that picture, subordinating logic, argument and even facts to his desire. The idealist therefore is a most dangerous citizen. The more perfect his ideal picture, the more dangerous he is and he further attracts support because of his sincerity.

What are the facts in the present case?. They are that in spite of all the efforts put into organization since the beginning, over half the engineers of the country belong to no engineering organizations at all. Those that do are not in one but in many —perhaps 600 Societies—each one created for a specific purpose and having therefore a particular attraction for a certain class of men. To believe that all engineers, or even the joining part of them could ever be corralled into a single Society one would have to have confidence, that he was better able to devise such a Society than any or all of his predecessors in the profession. The Institute, wisely as it has been managed and rapidly as it has grown, has not been able even to cover the technical side of the entire electric field. There have been a number of vigorous offshoots. If any one could imagine all engineers of every branch put together into one Society of any kind for any purpose—how long would they stay there? It would be human nature to split off—history supplies numberless supporting examples. In the light of the foregoing and for other less fundamental reasons as well, the conferees concluded that it would be far better to try to enlist the support of the large number of growing concerns with a membership aggregating perhaps 100,000 men and without abridging any of their present prerogatives, rather than to start all over again and try to build up a new kind of Society with a new membership and which in addition to the tremendous amount of time, effort and money required might expect to encounter the indifference, perhaps suspicion and in some cases the antagonism of the existing organizations. The primary objection to this plan is that the work of the new organization is to be quite different from that in which most of the old organizations have been engaged. Instead of dealing in the main directly with technical or inter-organization matter it will deal more largely with public affairs, and as the existing societies are not organized for this purpose, and in fact have not only not done it but have in some instances shown opposition to the idea, they should not be relied upon to back it now but on the contrary an entirely new body should be created, one that is not hampered or shackled in any way. The answer to this argument is that while the existing societies were not organized for the kind of work now contemplated several local affiliations of them have been functioning around many of the sorts of work proposed for a number of years and doing it very well, and that Engineering Council has already proved its efficiency and only needed a larger appropriation and the more representative membership to be afforded by the new plan to have occupied a much wider field.

Another basic question is that of finance. Nothing can be done without money. It needs no argument to prove that if the engineers of the country undertake this new activity they must pay its cost. There is no doubt that willing men will be found to devote their services to any good cause under the banner of their profession. That has been demonstrated over and over again, but money is needed as well, and the amount of work accomplished is largely measured by the funds available. The conferees all recognized this fact without argument, the only question to be discussed being how much money must be provided and how is it to be raised? I do not purpose discussing the details of this question except to say that as it is impossible in advance to prepare, much less to defend any very liberal budget because no definite expenditures can be allocated, and also for the reason that when the invitations are first presented to the various Societies very many of them will not be able to make large appropriations; so the conferees concluded that the modest figures used in their report were both a minimum limit and all that they should specify. Later on if the organization is formed and has a chance to demonstrate its value the

engineers of the nation will have ample information on which to alter the dues if they see fit.

The only other comment which I feel should be made is a word of caution and is born of my experience while serving the Institute on Engineering Council. That body has been beset on all sides to advocate or to oppose legislation and while it has not hesitated to do so when the questions involved were of a nature where the advice of engineers would be of particular value, it has steadfastly declined to become involved otherwise. Bearing this fact in mind my word of caution is against any policy which will cheapen the engineer. Our collective advice is valuable on subjects with which we are qualified by experience and training to deal and so long as we confine ourselves to such subjects and present a united front our influence can and will be considerable. But the minute we digress and begin to deal with matters outside the purview of engineering and subjects closely allied thereto, we sacrifice our preferred position and have no more claim to be heard than any body of educated citizens of similar numbers. We also would then almost certainly make the very serious mistake of misrepresenting our membership because while engineers can be safely counted upon to agree on fundamental facts they are of all shades of political belief and have as many different views as any one else regarding other questions. My word of caution therefore is really a plea to you to give this side of the subject your due thought and to make your views known at all proper times and places.

The work of any body of representatives depends on that of its constituents and the movement to create a national organization will be successful only to the extent that it is able to enlist the support of the individual members of the profession. I hope and expect to see the members of the American Institute of Electrical Engineers do their duty in this respect as they have always done it in connection with every task that has been put up to them in the past. I realize that much of what I have said to you is a repetition of what you already know but my excuse is that I regard the subject of so great importance to engineers as to bear repetition—not once but many times, and my desire to impress upon you that the future success of the plan is your problem and on you and your colleagues in other branches of engineering will depend its fate.

CONFERENCE OF ENGINEERING SOCIETIES

A conference of the governing bodies of its Member Societies called by Engineering Council, was held January 23 in Engineering Societies Building, New York, to discuss relations of Engineering Council and the bodies which it represents, to the engineering profession. The societies represented at the conference were the American Society of Civil Engineers, American Institute of Mining and Metallurgical Engineers, American Society of Mechanical Engineers, American Institute of Electrical Engineers, American Society for Testing Materials, and the United Engineering Society.

A discussion of the organization and work of Engineering Council was entered into thoroughly, and the financial conditions were discussed with a view to providing permanent financial support for Council or its successor. The recommendations of the Joint Conference Committee of the Development Committees of the Founder Societies were outlined; and the Conference Committee's plan, to bring into existence the comprehensive organization which it has proposed, was endorsed.

The meeting lasted all day and was harmonious and constructive, the spirit of cooperation being predominant. To make a federation of the entire engineering profession to carry on civic and other non-technical activities for the several societies, to centralize responsibilities, and still keep it a truly nation-wide movement, was clearly a problem, yet one which was felt could be carried to a successful and helpful solution, by forming an organization, broad in purpose and widely affiliated.

The discussions resulted in the adoption of several resolutions, it being understood that these actions were in the nature of recommendations to the societies. These included recommendations relating to the financing of Engineering Council pending the formation of the more inclusive affiliation of national and local engineering organizations. The endorsement of the Conference Committee's proposed plan for the affiliation of the Engineering Profession was expressed in the following resolution:

WHEREAS, this Conference of national engineering societies has considered the recommendations of the Joint Conference Committee of the four Founder Societies, therefore, be it

RESOLVED, that the Conference adopts in principle that report and requests the joint Conference Committee to call, without delay, a conference of representatives of national, local, state, and regional engineering organizations to bring into existence the comprehensive organization proposed.

The Conference Committee's plans and the method by which these plans were formulated, together with many of the considerations involved in this comprehensive movement, with an outline of what it connotes for the engineering profession, is set forth in detail in the admirable address of President Townley as printed above.

MIDWINTER CONVENTION

The Institute held its Eighth Annual Midwinter Convention, February 18 to 20, 1920 in the Engineering Societies Building, 33 West 39th Street, New York. The total attendance of members and guests was about 1100.

Wednesday Afternoon

On Wednesday afternoon, February 18th, over 260 members and guests took advantage of the Western Electric Company's invitation to visit the Bell System Laboratories. They were divided into groups under the leadership of guides thoroughly familiar with the equipment of the various laboratories.

During the three days of the Convention many members visited the principal power stations and other places of engineering interest in New York in accordance with arrangements which had been made by the Excursions Committee, consisting of Messrs. W. S. Finlay, Jr., chairman, Philip Torchio, N. A. Carle, W. G. Carlton, Preston S. Millar, Frank W. Smith and L. F. Morehouse.

The Wednesday evening session was called to order at 8.15 p.m. by President Calvert Townley who delivered an extremely interesting address on "Proposed Federation of Engineering Profession." The address is printed in full elsewhere in this issue. President Townley then called on Preston S. Millar, Manager Electrical Testing Laboratories who presented his paper on "Daylight Saving." He was followed by W. S. Gorsuch and E. J. Cheney who presented their respective papers on "Essential Statistics for the Comparison of Steam Power Plant Performance" and "Standard Graphic Symbols." This discussion which followed was participated in by the following men: D. McF. Moore, H. R. Summerhayes, C. R. Underhill, E. H. Martindale, R. S. Hale, A. B. Smith, W. I. Slichter, E. J. Cheney, Selby Haar, P. G. Agnew, Louis M. Meckler, Jr., Alexander Maxwell, O. C. Traver, and closure by the respective authors.

Thursday Morning

The second technical session was opened at 10.30 a.m. Thursday morning with W. S. Murray acting as Chairman. The subject of this session "Economical Supply of Electric Power for the Industries and the Railroads of the Northeast Atlantic Seaboard" was arranged in the form of a symposium. Mr. Murray's very complete presentation of the subject was followed by presentations by Malcolm Maclaren, Henry G. Reist, Charles F. Scott, Percy H. Thomas, N. W. Storer, Philip Torchio, S. T. Dodd, David B. Rushmore, Arthur O. Austin, E. E. F. Creighton, H. W. Buck and John W. Lieb.

The following resolution was offered by Mr. H. W. Buck:

Moved: That it is the sense of this meeting to recommend to the Board of Directors of this Institute to appoint a Committee, of which Mr. Murray shall be Chairman, to carry alongthis most excellent movement which he has initiated today.

Thursday Afternoon

On Thursday afternoon parallel technical sessions were held in the Auditorium and in one of the 5th Floor Rooms. At the 5th Floor session, Dr. Clayton, H. Sharp presided as Chairman. The first paper entitled "A Method of Separating No-Load Losses in Electrical Machinery" presented by the author, C. J. Fechheimer, was discussed by V. Karapetoff, W. F. Dawson and W. S. Slichter. The second paper of the session entitled "Inherent Regulation of D-C. Circuits" by A. L. Ellis and B. W. St. Clair was read by Mr. Ellis and discussed by V. Karapetoff, H. R. Summerhayes and L. W. Thompson. The last paper entitled "Measurements of Projectile Velocities" by P. E. Klopsteg and A. L. Loomis was presented by Mr. Klopsteg and discussed by E. E. F. Creighton and Roy Kegerreis.

At the Auditorium session Donald McNicol presided as Chairman. The first paper, read by the author J. H. Bell on "Printing Telegraph Systems" was discussed by George O. Squier, Edgar Russell, C. E. Davis, H. A. Emmons, P. M. Rainey, J. P. Edwards, E. R. Shute, R. E. Chetwood, D. Benjamin and John H. Cuntz.

The second paper on "Maximum Output Networks for Telephone Substations and Repeater Circuits" by G. A. Campbell and R. M. Foster was presented by Mr. Campbell and discussed by Lloyd Espenschied and O. B. Blackwell.

Thursday Evening

About 375 members and guests attended a Dinner-Dance at the Hotel Astor. This event, which has been a regular feature of Midwinter Conventions for several years past, was exceedingly enjoyable to all present and reflected great credit upon the Committee in charge, consisting of, Messrs. H. A. Pratt, Chairman, N. A. Carle, R. F. Jacobus, R. L. Jones, H. B. Logan E. W. Loomis, W. T. Morrison, F. A. Muschenheim.

Friday Morning

At Friday morning session, 10.30 a.m. S. G. Rhodes presided and three technical papers were presented the first on "A New Form of Vibration Galvanometer" was read by the author, P. G. Agnew and discussed by J. B. Whitehead, C. H. Sharp, W. H. Pratt and P. E. Klopsteg.

The second paper by T. R. Harrison and P. D. Foote on "Precision Galvanometer for Measuring Thermo E. M. F's." was read by H. B. Brooks and discussed by J. B. Whitehead, A. E. Kennelly, W. D. A. Peaslee, E. M. Hewlett and C. H. Sharp.

The third and last paper of the morning session "Notes on Synchronous Commutators" by J. B. Whitehead and T. Isshiki was read by Dr. Whitehead and discussed by P. G. Agnew, E. D. Doyle, A. E. Kennelly and J. H. Morecroft.

Friday Afternoon

On Friday afternoon, 2.30 p.m., S. G. Rhodes presided and called for the presentation of two papers. The first by A. E. Kennelly, R. N. Hunter and A. A. Prior on "Oscillographs and Their Tests" was presented by Dr. Kennelly and discussed by F. S. Dellenbaugh, R. N. Hunter, B. W. St. Clair and N. E. Bonn.

The second paper by H. B. Brooks on "The Accuracy of Commercial Measurements" was read by the author and discussed by W. H. Pratt, J. S. Craighead, E. P. Peck, F. V. Magalhaes, F. H. Baumann, Alexander Maxwell, H. H. Sticht, B. W. St. Clair, A. L. Ellis and Harvey P. Sleeper.

A. I. E. E. DIRECTORS MEETING

FEBRUARY 18, 1920

The regular monthly meeting of the Board of Directors of the American Institute of Electrical Engineers was held at Institute headquarters, New York, on Wednesday, February 18, 1920, at 10:30 a. m.

There were present: President Calvert Townley, New York; Past President C. A. Adams, New York; Vice-Presidents C. E. Skinner, Pittsburgh, N. A. Carle, Newark, N. J., Wills Maclachlan, Toronto; Managers Charles S. Ruffner, Wm. A. Del Mar, W. I. Slichter, L. F. Morehouse, New York, Charles Robbins, Wilfred Sykes, Pittsburgh, E. H. Martindale, Cleveland, Walter A. Hall, West Lynn, Mass., L. E. Imlay, Niagara Falls; Treasurer George A. Hamilton, Elizabeth, N. J.; Secretary F. L. Hutchinson, New York.

Upon the recommendation of the Finance Committee, monthly bills amounting to $15,682.97 were approved.

Upon the recommendation of the committee appointed to consider the time and place of the Annual Convention for 1920, the Board voted to hold the Convention at the Greenbrier, White Sulphur Springs, W. Va., June 29 to July 2.

A communication was presented from Vice-President Fisken relating to the Pacific Coast Convention of 1920; and upon its recommendation it was voted that the Pacific Coast Convention for 1920 be held at Portland, Oregon, July 21-23.

A report was presented of a meeting of the Board of Examiners held February 16, 1920; and upon the recommendation of the Board the following action was taken upon pending applications: 186 Students were ordered enrolled; 141 applicants were elected to the grade of Associate; 6 applicants were elected to the grade of Member; 12 applicants were transferred to the grade of Member; 2 applicants were transferred to the grade of Fellow.

President Townley announced the appointment of the following as members of the Tellers Committee, to canvass and report upon the nomination and election ballots in connection with the coming election of officers of the Institute: Messrs. Edward J. K. Mason, Chairman, W. P. Abendroth, Charles M. Fulk, P. Norton, and P. C. Paquette.

Upon the recommendation of the Chairman of the Sections Committee, a request for authority to organize a Section of the Institute at Worcester, Mass., was granted.

At the request of the American Engineering Standards Committee, the Board approved the admission of the National Safety Council and the Fire Group as members of the American Engineering Standards Committee.

It was voted that the next meeting of the Board of Directors be held at the Duquesne Club, Pittsburgh, March 12, at 10:30 a. m. As announced elsewhere in this issue, a meeting of the Institute will be held in Pittsburgh on the same date.

In addition to these routine actions many other matters relating to important activities and the general policy of the Institute were discussed. Reference to these matters may be found in this and future issues of the JOURNAL under suitable headings.

GENERAL ENGINEERING CONGRESS AT BATAVIA, JAVA, MAY 1920

The Institute has just received through the Director, Bureau of Foreign and Domestic Commerce, Dept. of Commerce notice of a General Engineering Congress to be held at Batavia, Java in May 1920. Two languages, namely: English and Dutch will be employed during the Congress and all publications will be published in both languages. The official opening of the Congress will take place at 7 p. m. May 8th and the program embodying regular sessions, excursions, dinners, etc. will extend to Saturday May 15.

The Secretary of the Institute will be glad to receive the names of any members who expect to attend this Congress.

UNITED ENGINEERING SOCIETY

EXTRACTS FROM REPORT OF TREASURER FOR CALENDAR YEAR 1919

The Surplus Account on December 31, 1918 showed a balance of $5,533.43. This amount has been increased by the surplus from the operating accounts during the year of $9,557.28 making a total on December 31, 1919 of $15,090.71. Of this amount $10,000.00 has been transferred to Depreciation and Renewal Fund, leaving a balance in Surplus Account of $5,090.71.

The Gross Operating Expenses for the year 1919 were $66,812.89, as compared with $66,505.57 for the year 1918, an increase of $307.32.

The funds available for the Library Board, and spent under its direction during the year, amounted to $23,876.64.

The funds available for Engineering Council, and spent under its direction during the year, amounted to $49,012.38, of which $940.07 remained unexpended.

The General Reserve Fund of $10,000 created by the Board of Trustees at a meeting held November 18, 1914 to be available to take care of unforeseen fluctuations of income and outlay, has been preserved intact, there arising no calls on this fund during the year 1919.

The Depreciation & Renewal Fund at the beginning of the year 1919 amounted to $86,163.78. During the year this fund has been increased by the sum of $4,035.22 for interest earned by the investments for this fund and by $10,000.00 added from the surplus at the end of the year, making a total of $100,199.00 on December 31, 1919.

In accordance with the authorization of the Board of Trustees, February 27, 1919, the sum of $13,000.00 was invested in Government of United Kingdom of Great Britain and Ireland, 20 year bonds, 5½'s due February 1937. $5,000.00 being reinvestment of proceeds from Bethlehem Steel Co., 2 year Sec. Gold Notes matured February 15, 1919 and $8,000.00 cash transferred from Surplus to Depreciation and Renewal Fund.

The following summary shows the amounts of the funds held by U. E. S. as of December 31, 1919:

Depreciation and Renewal Fund December 31, 1918	$86,163.78
Interest on invested funds during the year 1919	4,035.22
Transfer for the year 1919	10,000.00
Total	$100,199.00
General Reserve Fund	10,000.00
Engineering Foundation Fund	303,374.80
Library Endowment Fund	102,559.70
Total	$516,133.50

Treasurer's Receipts and Payments, Year of 1919

Receipts

Cash on hand January 1, 1919		$12,869.60

ANNUAL DINNER OF BOSTON ENGINEERS

The 11th Annual Dinner of The Engineers of Boston and Vicinity will be held on Tuesday evening March 30th, in the main auditorium of The Boston City Club, dinner at 6.15: addresses 7:45. The principle speakers and their subjects will be, Paul D. Cravath, "Some Economic Aspects of the Treaty at Paris;" Dean Roscoe Pound, "Social Engineering." Paul D. Cravath, Attorney, New York City, was one of the American Representatives at Paris during the War. Dean Roscoe Pound is Dean of the Law School of Harvard University, Cambridge, Mass. The dinner is under the auspices of The Boston Section A. I. E. E. and A. S. M. E. and the Boston Society of Civil Engineers. It is, however, open without further invitation to members of any other societies and in fact anyone interested in the engineering profession whether society member or not. Tickets $3.75, obtainable from Ira Cushing, 84 State St., Boston, Mass.

ENGINEERING COUNCIL

Headquarters: 29 West 39th Street, New York

Organized by several national engineering societies, including the Institute, to represent their membership in matters of common interest, especially relationships of engineers to the public and to governments. Council is one result of a wide movement to enlarge the activities of engineers for patriotic, social and personal welfare.

EXTRACTS FROM ANNUAL REPORT FOR YEAR ENDING FEBRUARY 1920

Engineering Council has completed its third year, continuing work previously started and taking up many new projects. During this past year it has been impracticable for the Secretary to make more than a few visits to engineering societies, and they were to those relatively near New York. The combination of duties for United Engineering Society, Engineering Foundation and Council, together with lack of funds, prevented further visits. Nevertheless, many personal visits on behalf of Engineering Council have been made to groups of engineers from coast to coast by the Chairman; by Representatives Baker, Cooley, Hollis, Loweth, Moore, Skinner and Townley; by Chairman Leighton, of the National Service Committee; and by Secretaries Stoughton and Rice, of the Mining and of the Mechanical Engineers. Several local societies, by letter or personal representative, have requested and received advice and other assistance from Council's office.

The American Society for Testing Materials completed qualifications as the fifth member society, in February, and has since taken an active part in Council's work.

Council held five meetings during the year: three in New York, one in Chicago, in April, and one in Washington, in June. The total expenditures for the calendar year 1919 were $49,000, including $25,000, advanced by the Chairman for the expenses of the Washington office, opened January 1, 1919.

In April, Engineering Council called together in Chicago, representatives of seventy-four technical organizations having 105,000 members, to discuss an effort to secure a National Department of Public Works. To conduct and finance this movement there was created a body now known as the National Public Works Department Association. Branch organizations have been established in most of the States and work has been directed chiefly from Council's Washington office. In September Engineering Council became a member of the Chamber of Commerce, U. S. A.

In January, 1919, by public hearing Engineering Council aided the reinstatement of 350 engineers unfairly dismissed by the City of New York. It also assisted late in the year in securing better salaries for these and other engineers and in preventing a recurrence of last year's unfortunate conditions.

Late in 1919, and in January, 1920, committees were appointed on types of Government Contracts, on Military Affairs, on Co-operation with the American Institute of Architects, and on co-operation with Association of Russian Engineers in America. In response to request, special assistance was given the Signal Corps, U. S. Army, in connection with bills before Congress.

Other notable events in the year's history are: Council took part in organizing a National Board for Jurisdictional Awards in the Building Industries, and has a member thereon. Council appointed three representatives to co-operate with equal numbers from the American Institute of Architects and the Associated General Contractors of America, to determine a policy regarding "Payment for Estimating."

To the Reconstruction Commission of the State of New York, a special committee of engineers, appointed by Council, gave assistance in preparing a Report on Retrenchment and Reorganization in the State Government. On a National Budget System, Council presented testimony through four delegates sent to Washington on invitation of the Select Committee of the House of Representatives. Council gave much assistance to the War Department Claims Board in securing technical experts to review reports on claims amounting to approximately two billion dollars. To expedite completion of topographical maps of the United States, President Wilson, in response to a communication from Engineering Council, by Executive Order, constituted a Board of Surveys and Maps, of one representative each from the fourteen map-making agencies of the Government, and invited representatives of Engineering Council and engineering and scientific societies to cooperate. The new board set up a permanent organization January 13, 1920.

Engineering Societies Employment Bureau, organized immediately after the Armistice was maintained throughout the year. It registered 5400 engineers, the majority of whom had been in Military or Naval Service, and aided a large proportion to find positions. It rendered service to both employers and employees without charge, but at a cost to the Founder Societies of more than $16,000. The Secretaries of the Founder Societies were the Board of Directors. At the end of the year, the Bureau was detached from Engineering Council by actions of the Founder Societies.

A Committee on Classification and Compensation of Engineers, created in March, worked in three sections dealing with engineers in the employment of (1) Federal Government, (2) Railways, (3) Cities and States. (See February JOURNAL; also elsewhere in this issue).

The Committee on Licensing Engineers, after fourteen months' work, presented in December, a valuable report accompanied by a "Recommended Uniform Registration Law, to regulate the practise of professional engineering, architecture and land surveying."(See February JOURNAL.)

The Fuel Conservation Committee continued co-operation with the Government, and recommended support of a Federal appropriation for a survey to determine the desirability of a superpower system in the industrial region extending from Boston to Washington.

The Water Conservation Committee appointed correspondents in twenty-seven States, is seeking correspondents in other States, is collecting useful information, and is aiding the Maine Water Power Commission on questions of policy in response to a request from its chief engineer.

Through its committees and its officers, Engineering Council has considered and acted upon many other matters. Its labors, some of which have been in progress for a long time, are bearing good fruit. As these results become known throughout the country, Council's faithful, quiet work is coming to be better understood and more highly appreciated. Many written and spoken words of commendation have been received. Council is better established than ever before, is known and recognized in governmental circles and has more clearly determined the kinds of work desired of such a joint organization by the engineering societies. Its usefulness has been limited by insuffici-

ency of publicity, but it has had small resources for developing suitable agencies; it has been dependent largely upon its member societies and upon willing but uncertain voluntary services.

Council believes that it has done much good work; it has proceeded carefully in an endeavor to build lastingly. Its future is entirely in the hands of its member societies, which it is ready to serve in the ways directed, until it shall be succeeded by the new organization proposed by the Joint Conference Committee. Although complete changes will probably be made in personnel, Council aims to turn over to its successor, whenever the time comes, useful machinery in good order and active operation, so that there may be no hiatus in the "welfare" work of the Engineering Profession.

CLASSIFICATION AND COMPENSATION OF ENGINEERS*

The Just Basis for Fixing the Compensation of Engineers

In order to determine what is a fair rate of compensation for engineering service at the present time, the question may be approached from two different points of view: First, what increase should be made in engineers' pay to compensate for the great reduction in the value of the dollar which has taken place in the last five years? Second, how may the intrinsic value of engineering service be determined?

The Decrease in Value of the Dollar

A great deal of misunderstanding and injustice would be avoided in all our industrial relations were there a clear understanding of the fact that all prices today, whether of wages or salaries, or commodities, must be compared with the change which has taken place in the value of the dollar before it can be determined whether the price, measured by an absolute standard, has moved up or down. It should be obvious to everyone that the value of the dollar is measured solely by its purchasing power. Whether it be a dollar received as wages by workmen, a dollar received as salary by an engineer, or a dollar received by a manufacturer in payment for goods sold, the actual amount of value which will be received in each case *will depend upon the average amount of other commodities which the dollar received will purchase.*

Changes in "Cost of Living" and in "Value of the Dollar" are Not the Same

The customary reference to the general increase of prices above reviewed as "the high cost of living" has tended to confuse the minds of many people. Some employers have argued that the high cost of living was not their affair. They have declared the real trouble to be "the cost of high living." On the other hand engineers or other professional workers, and many classes of salaried men have hesitated to press claims for increased pay on the ground that changes in the cost of living make it difficult to live on their incomes. Such men rightly feel that their living expenses are their own private affair.

When, however, it is clearly understood that what has taken place is a change in the value of the dollar, the claim for an increase in the rate of pay measured in dollars rests on entirely different ground. The proper and dignified position for the engineer is to assume that his work should receive at least the same compensation in absolute value that it received five years ago and that therefore the compensation measured in dollars should be increased by whatever amount is necessary to offset the decreased value of the dollar.

There can be no denial of the justice of this claim, even though the difficulty of satisfying it to the full extent in many departments of engineering work is recognized. The compensation of many engineers is dependent upon laws and ordinances, custom and precedent. Great inertia must often be overcome to effect a change. In many cases the compensation of the engineer, like that of many other public servants, is dependent upon revenue raised by taxation; and the difficulties in increasing tax rates to correspond to the great decrease in the value of the dollar are known to everyone.

*Extracts from Appendix to Report of Committee, which report was published in the February JOURNAL.

Engineers engaged in business on their own account have to meet the difficulty of raising their fees to offset the changed value of the dollar, a task especially difficult in fields of engineering where work is inactive and the competition for it is keen; yet without such increase they cannot adequately raise the pay of their own employees. This illustrates anew the need for emphasizing the change in value of the dollar, rather than the change in living costs. The former is at once recognized to bear directly on fair prices for goods sold and for the fees charged by professional men as well as on wages and salaries.

On the other hand there are many cases where there is no real obstacle to a prompt adjustment of the engineer's compensation to the full amount indicated by the decreased buying power of the dollar. In carrying on construction work, the salaries paid to engineers are a small percentage of the total cost. The wage workers, both those organized in trade unions and even the unskilled and ignorant laborers on the work, have received increases in compensation in many cases fully equal to the change in the value of the dollar and in some cases far exceeding it. If the engineers on such work are paid the same percentage of the total cost that they were in 1914, their increased pay will fully offset the changed value of the dollar. The same thing is true of engineers employed in manufacturing industries, and here the compensation of engineers has been largely increased.

Justice to the Salaried Men

At this time especially, employers who represent invested capital and those responsible for work in the public service, stand in great need of the loyal support and cooperation of their salaried professional staff. It is exceptional where salaries have been increased to fully correspond to their decreased purchasing power. The injustice in thus reducing the rate of compensation for loyal and efficient service paid to the very men on whose brains and fidelity the country is more dependent than on any other class is truly a fatal error.

How Long Will High Prices Stay

There has been reluctance to raise salaries to correspond to the changed value of the dollar because of the idea that prices were to drop back with the conclusion of the war. So far from this being the case, the records show that following the lull in business after the armistice prices have risen above even the war time scale and are now at the highest point ever reached. Business has largely readjusted itself to the changed conditions and the activity in some lines exceeds that registered during the war.

At the bottom of the changed price conditions is the surplus of demand over supply. The only two things which can restore prices to their former level are increased production or decreased consumption. The outlook is that it will take years to again organize the world's equipment for production and distribution, including finance, transportation by land and sea, and merchandising, so that the demands of consumers may be met as before the war and prices be brought back to former level.

If this analysis be correct, then all classes of workers whose compensation is below the general level will continue to suffer a hardship. The inevitable tendency will be to drive the competent men in these poorly paid callings out into other better paid occupations. Delay in adjusting the pay of the engineer to compensate for the decreased value of the dollar, therefore, does serious harm not only to him but to the public.

It may well be argued further that the high scale of prices or low dollar value has continued now for fully three years. During that time the engineer who has had but little increase in salary has suffered a heavy monetary loss through causes entirely beyond his control. The present price level is not considered merely temporary by such of our Government agencies as the Department of Labor and the Federal Reserve Board or by such

economists as Irving Fisher* and J. S. Holden†. Substantial relief from the high cost of living therefore cannot reasonably be expected through a decrease in prices; it must be met by increases in salaries.

From the above considerations, the Committee feels justified in urging that a readjustment of compensation should be based on the assumption that the present scale of prices is to continue for an indefinite time.

The Intrinsic Value of Engineering Service

It will be generally agreed that the salary of an engineer ought to be at least sufficient to enable him to live in the manner which his position and responsibility call for, and in addition to repay within a reasonable time the investment in time and money he has made in gaining the education and experience which is necessary for his work.

The Living Wage Principle

There is a wide general acceptance of the principle that the worker in any occupation should receive at least a reasonable living wage. By a "living wage" is meant the amount which will maintain in decency and comfort both the incumbent of the position and his dependents.

There are certain positions which are ordinarily occupied by young men and women who are starting on their life work and who have not yet assumed family responsibilities. In so far as the incumbents of these positions fill them temporarily as a means of advancement to positions of greater compensation —in effect serving as apprentices—the living wage need not be based on a "family" standard. When, however, any position is likely to be occupied more than temporarily by individuals of an age at which they should naturally assume family responsibilities, the minimum salary for the position should not be less than that necessary to maintain an average family in respectability.

Why Engineering Work has Been Inadequately Paid

Unfortunately there has been for fully a decade a tendency to lower the pay of engineers. The law of supply and demand has operated to reduce the pay of engineers in many branches of the profession far below the standards above defined.

This has not benefited the public. On the contrary by paying too low a rate for engineering service, the inevitable tendency has been to lower its quality. This has been especially marked in the case of engineers in Federal, State and Municipal service. Here the inertia which prevails in all public affairs has prevented the engineers from receiving more than a trifling part of the increase in pay, measured in dollars, that is required to offset the shrinkage in the dollar value.

The obvious result has been to drive out of the public service the best and ablest men, who can obtain better positions elsewhere, and to leave only the men who by reason of age or inferior ability cannot make such a change.

Cheapened Engineering Service Means Waste and Danger

It cannot be too strongly emphasized that the public loses through cheap engineering service many times the amount it may seem to save through lower salaries. The professional engineer in a responsible position in designing, constructing or executive direction of important work should have initiative, sound judgment, broad knowledge and executive ability. Lack of these qualities often results in great loss of money, often by needlessly increasing the cost of work of which the public never knows. Safety of life and limb is also so frequently dependent on the skill and fidelity of the engineer that danger is incurred when the quality of engineering service is sacrificed through a false idea of economy. The investigation of the Quebec bridge disaster of 1907 showed that the engineer primarily responsible for the safety of its design was being paid at so niggardly a rate as to be unable to provide a sufficient and competent staff to properly supervise the work.

*Fisher, Irving. The New Price Revolution, U. S. Dept. Labor, 1919.
†Holden, J. S. Prices During the War and Readjustment period, U. S. Dept. of Labor, April, 1919.

The movement, therefore, to give engineers just compensation for their services is not merely a movement for the benefit of the engineering profession. It is even more a movement to benefit the public by securing for it a high quality of engineering service.

This matter deserves emphasis here because where readjustment of salaries has taken place to compensate for the changed value of the dollar it has been common to confine the increase to the lower paid men and to do little or nothing for the men receiving salaries above $2500 to $3000. There is no longer an excuse for this, as the above review amply proves. The measure of seeming economy, also, is very small; because the engineers in the higher poistions are few in number compared with the rank and file of professional workers.

Routine Workers in the Profession

It is frankly recognized that there is another class of technical work of a routine order which calls for little in the way of initiative, originality or judgment. Much of this routine technical work in the field, the office, the shop, or the laboratory can be and is being done by boys and young men with limited education and no more training than that afforded by a correspondence school or a few months study in a trade school. Most of this work does require, however, a degree of reliability and fidelity which deserves fair compensation. The best guide to fair rates of pay for this class of technical workers is found by comparison with the standard rates of wages paid to skilled workers in the trades. These workmen are now generally receiving rates of pay much higher than the routine technical worker and in many cases higher than even the engineer who carries large responsibility for design or administration.

The Federal Government is now paying thousands of its highly trained clerical and technical force less than a living wage. Except for the temporary bonus of $240 a year for positions paying salaries of $2500 or less, no attention has been paid to the constantly diminishing purchasing power of the salaries paid to this class of employees. On the other hand the Government has given full recognition to increased living costs in fixing the wages of organized labor.

A "shipfitter" in the Navy Yard, for example, receives $1750 a year while he is learning how to do his work. After three months of apprenticeship he gets $2000. If he is made a "straw boss" in charge of 12 or more men, he gets $2450, and if a "sub-foreman" in charge of 30 or more men, he gets $2900. A blacksmith (heavy fire) gets $2400. A "hammer and machine forger" (heavy) gets $3700.

In many instances the amount paid for skilled labor is greater than the amount paid to the trained Government engineer. Over 40 of the labor crafts were awarded a rate of wage of $2000 and more by the Labor Adjustment Board.

The skilled laborer is not required to know how to read or write, and he may receive full pay after an experience varying from two weeks to six months. The Government engineering employee, on the other hand, to get an equivalent amount of pay, must have had from two to eight years' experience if he is not a technical graduate, and in many instances will not be admitted at all without a technical degree and then only with from two to four years' practical experience.

Many other comparisons might be made between the worker at a trade or the factory employee and the routine worker in engineering, showing how low is the pay of the latter compared with the former; but no further proof is necessary to show that the technical worker is not receiving what his services are worth.

The inevitable result of such underpaid service is a deterioration in its quality. The men in these lower grades have as a rule not the same incentive of professional pride that often keeps the men carrying large responsibilities faithfully at work, even when their pay is inadequate.

Even though a temporary oversupply of men trained in engineering work may make it possible to keep salaries for these brain workers below the wages of laborers, the inevitable result

will be a dissatisfied working force, which carries out the daily routine without energy or good will, and the public's work will not be done with efficiency or economy.

AMERICAN ENGINEERING STANDARDS COMMITTEE

After almost three years of investigation by the engineering fraternity, under the guidance of Professor Comfort A. Adams as Chairman, the revised constitution of the American Engineering Standards Committee, along with by-laws and rules of procedure, has been adopted, and has been ratified by the A. S. C. E., the A .I. M. &. M. E., the A. S. M. E., the A. I. E. E. and the A. S. T. M., and the three Government Departments, of Commerce, Navy and War. Each of these interests have three representatives, and although the Committee as it exists today consists of twenty-four members, the new Committee is of very wide scope and allows the direct or indirect participation of anyone interested in standardization.

Mr. A. A. Stevenson, the newly elected Chairman, is a Past-President of the American Society for Testing Materials, and Dr. P. G. Agnew, formerly of the U. S. Bureau of Standards, is now Secretary with headquarters at the Engineering Societies Building, 29 West Thirty-ninth Street, New York City.

The American Engineering Standards Committee makes it possible to give an international status to approved American engineering standards and to cooperate with similar organizations in other countries. Similar organizations are now functioning in Great Britain, France, Switzerland, Holland and Canada.

The American Engineering Standards Committee has already approved specifications for standard pipe threads, and are representing America on this subject at an international conference in Paris. Cooperation is in progress with the National Screw Thread Commission, looking forward to standard screw threads. The Committee is also in active cooperation with the Canadians on bridge specifications, with the British on machine tools and with the Swiss on ball bearings.

A conference of practically all national organizations interested in industrial safety has unanimously voted that all industrial safety codes should be prepared under the auspices of the American Engineering Standards Committee.

Any organization may request the Committee to approve standards which it has formulated, or to approve committees that it has appointed, and by so doing becomes a sponsor society. Two or more organizations may act as joint sponsors. Approval of a standard is given when it is the substantially unanimous conclusion of a section committee made up of representatives of producers, consumers and general interests, and so selected that all interests concerned have adequate representation on the section committee.

In addition to the work of assistant in the selection of committees and certifying that their work has been done under proper conditions, the Committee will act as a bureau of information regarding standardization.

CURRENT ENGINEERING TOPICS

POWER BILL STATUS

As this issue goes to press, it appears probable that the Water Power Bill, which has passed both the House and Senate, will come up for active consideration before the conference committee within a few days. This is made possible because the conferees serving both on the Railroad Conference Committee and Power Conference Committee, were released when that Bill was agreed to and sent back for final passage. It is contemplated that at least a month will be required for the adjustments which will be made in conference.

The conferees on the part of the Senate are—Jones of Washington, Nelson of Minnesota, Bankhead of Alabama, Smoot of Utah, Fall of New Mexico, and Myers of Montana; on the part of the House—Esch of Wisconsin, Sinnott of Oregon, Haugen of Iowa, Sims of Tennessee, Taylor of Colorado and Lee of Georgia.

It is realized by engineers that this legislation does not give all that could be wished or hoped for in the way of a national power policy or in the way of administering that policy, but when it is realized that this legislation has come through a long and tedious course, with very active opposition at every turn, it should be taken at its face value as at least a good beginning and as an opening upon which further improvement can very logically be based in the light of experience that will be obtained from the initial operations under this bill.

CONSERVATION THROUGH ENGINEERING

Past-Secretary of the Interior, Mr. Franklin K. Lane, has given considerable attention to the engineering features of the work of his department as is evidenced by the frequency and comprehensive references made to engineering work in the last annual report of the Secretary of the Interior, and especially to the printed extracts of that report which have been gotten out under a separate cover, for the purpose of lending cooperation to engineers.

The recent coal strike and the attention given it by the Interior Department is covered in considerable detail with pertinent questions asked and answered as to the means of conserving coal and meeting future emergencies of this kind. Under the heading "White Coal and Black" the question of waterpower is treated briefly.

Petroleum from the standpoint of its production from oil-shale and its use as fuel and generating power is treated with a comprehensive summary. It will be recalled that Mr. Lane was especially active with broad plans for soldier settlement legislation,—it was he that first introduced soldier settlement plans. Other phases of the reclamation and development program are covered in an interesting manner.

"Conservation Through Engineering" is a public document known as Bulletin No. 705.

UTILIZING GOVERNMENT INVENTIONS

In order that the public, the industries and the Government Departments may get the full benefit of scientific inventions and patents of departmental employees, a bill has been introduced by the Senate Committee on Patents, proposing to give the Federal Trade Commission authority to arrange for the development of useful inventions, patents and patent rights in the broadest way. This procedure is to be under such regulations as the President shall prescribe. The cooperation of all scientific or other agencies of the Government is assured for the discharge of the duties of the Federal Trade Commission.

The Federal Trade Commission is authorized to collect fees and royalties for licensing the inventions, patents and patent rights in such amounts as the President directs and is to deposit these fees in the United States Treasury, except the necessary percentages to be reserved in a special fund to be used to remunerate the inventors for meritorious ideas. The appropriations of Governmental Departments are made available for the payment of fees charged by the Patent Office in connection with the granting of patents under this Act.

PATENT LEGISLATION

Legislation covering the administration of patent law, the status of the Patent Office and our international relations in patent work have been very active in Congress. The House has passed a bill ratifying a Patent Convention which will enable holders of patents in this country and South American countries to have their patents registered and cleared through a common office at Havana. The registration fee is very small,—only a fraction of what it used to cost to have these patents registered.

The Senate and House bills authorizing the Federal Trade Commission to accept and administer inventions, patents, and patent-rights have been reported to both houses. This is for the purpose of benefiting and encouraging the public in an effort to stimulate inventions and to encourage their industrial use. This bill provides for cooperation as between individuals, Government and other agencies, and with scientific agencies of the Government. The House patent bill providing for increase of force and salaries in the Patent Office has been rewritten and reported to the House calendar. It provides that the Commissioner of Patents shall receive $6,000 annually; First Assistant to Commissioner, $5,500; and the Assistant Commissioner of Patents $4,500, with five examiners in chief, $5,000 each. Other salaries are raised in proportion.

Bill proposing to establish a Court of Patent Appeals has been re-written by sub-comittee of House Patents Committee and will be introduced to the House calendar shortly. Bill proposing to make a separate establishment of the Patent Office is now under consideration by another sub-committee.

THE EDISON PIONEERS

The Edison Pioneers tendered a luncheon and reception to Mr. Thomas Alva Edison and his family at Orange, New Jersey on February 11th, 1920 on the 73rd anniversary of his birth. Many interesting and unique features added to the interest of the occasion and supplemented the Annual Addresses of the retiring President Mr. John W. Lieb, Past President Francis R. Upton and the well chosen remarks of Mrs. Edison who responded for Mr. Edison.

At the Annual Meeting of the Edison Pioneers which formed part of the ceremonies the following officers were elected for the ensuing year: President, Major William J. Hammer; Vice Presidents—Alfred W. Kiddle, Samuel Insull, Charles L. Edgar, Sydney B. Paine; Executive Committee—Francis R. Upton, John W. Lieb, Dr. Edward G. Acheson; Secretary—Robert T. Lozier; Treasurer—Frederick A. Scheffler; Historian— William. H. Meadowcroft.

SCOPE OF THE INSTITUTE

In the address of President Townley at the opening session of the Midwinter Convention of the Institute, which is printed in full elsewhere in this issue, attention is called to the desirability of the Institute confining its activities to matters within the scope of engineering or closely allied subjects.

This topic was also discussed at a meeting of the Board of Directors of the Institute held February 18, at which time the following resolutions were adopted for the purpose of reaffirming the well-established policy of the Institute.

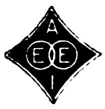
WHEREAS, many requests are received by the officers of the Institute and its Sections and Branches for support of candidates for political office and for various movements in activities outside of the field of engineering,

RESOLVED, that the attention of the membership be called to the undesirability of the Institute expressing views purporting to represent the collective will of the national, or any local, organization in matters outside of the scope of engineering and upon which the membership may hold conflicting opinions.

RESOLVED FURTHER, that attention be called to Section 61 of the By-laws, which reads as follows:

"SEC. 61. The principal work of a Section shall be the holding of regular meetings for the presentation and discussion of papers on matters relating to electricity, and to the allied arts and sciences. No action which may purport to represent the policy or organization of the Institute, or of any Section, shall be published or communicated to any party or parties who are not members of the Institute, without the approval of the Board of Directors."

NEW SIZE OF EMBLEM



This is a full size reproduction of a new membership badge, which has now been provided to meet numerous requests of Institute members for a smaller emblem. This badge which is half the size of the original is available in the vest pin, lapel button and scarf pin styles only, all patterns in solid 14k gold and finished in the same style as the larger membership badge. The lapel button is equipped with a screw back of plated gold. The price of the vest pin and lapel button styles is $3.00, and the scarf pin $3.50.

Members who desire to return their old membership badges for credit on the purchase of a new badge, will be allowed a refund of $1.00 for the return of a vest pin or watch charm, or $1.25 for the lapel button.

On account of limited space, the new badge will be provided without engraving.

INDUSTRIAL SAFETY CODES

On December 8th there was held at the Bureau of Standards in Washington a conference on industrial safety codes, at which there were representatives of practically all national organizations interested in industrial safety. The conference grew out of an earlier one held on January 15th, 1919.

After a thorough discussion the consensus of opinion was that there should be a large number of industrial safety codes developed during the next few years.

The subject is far-reaching. Vast financial and industrial interests are involved and the welfare of more than six million workers is directly involved, in the work of a single organization, the National Safety Council.

The conference unanimously voted that the preparation of all such safety codes should be under the auspices and rules of procedure of the American Engineering Standards Committee. In accordance with the recommendation of the conference, the American Engineering Standards Committee requested the International Association of Industrial Accidents Board and Commissions, the Bureau of Standards, and the National Safety Council to organize a Joint Committee on Safety Codes, this Committee to include representatives of these bodies, and such others as they may consider advisable, with the understanding:

(a) that this Joint Committee shall report upon safety codes required, priority of consideration of the codes, and sponsor bodies for their preparation.

(b) that the Joint Committee be requested to make a progress report by February 1st, 1920.

In compliance with this request of the Standards Committee, the three bodies have organized such committee.

The Committee held its first meeting in Washington on January 9th, at which time tentative recommendations were formulated for some thirty safety codes. It is expected that the Committee will be able to render an important preliminary report in the near future.

ENGINEERING SOCIETIES LIBRARY

The library is a cooperative activity of the American Institute of Electrical Engineers, the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers and the American Society of Mechanical Engineers. It is administered for these Founder Societies by the United Engineering Society, as a public reference library of engineering and the allied sciences. It contains 150,000 volumes and pamphlets and receives currently most of the important periodicals in its field. It is housed in the Engineering Societies Building, 29 West Thirty-ninth St., New York.

In order to place the resources of the Library at the disposal of those unable to visit it in person, the Library is prepared to furnish lists of references to engineering subjects, copies or translations of articles, and similar assistance. Charges sufficient to cover the cost of this work are made.

The Director of the Library will gladly give information concerning charges for the various kinds of service to those interested. In asking for information, letters should be made as definite as possible, so that the investigator may understand clearly what is desired.

The library is open from 9 a. m. to 10 p. m. on all week days except holidays throughout the year except during July and August when the hours are 9 a. m. to 6 p. m.

REPORT FOR 1919

The annual report of the Library Board of the Engineering Societies Library for 1919 has been issued, from which the following items have been abstracted.

Contents. During 1919 the library received by gift 5707 books and pamphlets, and by purchase 785 books and pamphlets, making on December 31, 1919, a total permanent collection of 152,091 publications, all unaccessioned material having been examined during the year and either accessioned or placed among the duplicates.

Use. The number of readers using the library during 1919 showed a marked increase over 1918. The attendance during recent years has been:

1915	12,820
1916	13,848
1917	11,381
1918	15,063
1919	22,042

The low figure for 1917 is accounted for by the fact that it was necessary to close the library for a considerable period during that year.

In addition to the readers, the library has received many mail and telephone inquiries, over 2500 persons during the year having been helped by the library not represented in the attendance figures nor in the records of the Service Bureau, which has cared for work requiring extended research, the preparation of translations, and copies of articles and bibliographies. During the year 552 searches, chiefly bibliographic, were prepared in answer to specific inquiries. Some of these were of great extent, requiring the time of one or two people for weeks and even months. The number of translations made was 71, containing 227,300 words.

The value of the equipment for making photographic copies of articles has been more evident than ever before. The orders amounted to 2319 and required 23,951 prints. This is an increase of 101 per cent over 1918, showing that this form of assistance is widely appreciated. Copies have been made for engineers on every continent.

Technical Work. Arrangements for examining unaccessioned material, cataloging new accessories, and recataloging old material were made in May. Miss Margaret Mann, formerly Chief Cataloger of the Carnegie Library of Pittsburgh, was engaged as cataloger, and the department began work on July 1, since which time it has covered extensive ground. The total number of volumes cataloged or recataloged during the year was 8993; and aside from these much time was spent in collecting sets from their various locations, in correcting inaccurate records and in collating the sets of periodicals and government publications. An index to the new catalog, containing 2920 entries, was compiled, and 6899 cards were added to the catalog.

The general principles of classification and cataloging have been described in a report by Director Harrison W. Craver. He explains, in brief, that the new catalog will substitute for all the old catalogs an author catalog and a classed subject catalog, the latter to be accompanied by a very full index. The Brussels classification is the scheme most adapted to the library's needs—that is the Dewey classification as extended and modified by the Institut International de Bibliographe. This has more international acceptance than any other system and its principles and notations are quite generally understood. The fact that many users of the catalog will have some previous familiarity with its system will enable them to use it more readily and with less assistance; and the system is sufficiently comprehensive and elastic to meet successfully any demand that the library may have to place upon it.

Staff. Changes in the staff have been less frequent than in previous years, and the effect of experience in this library has been favorably shown in more helpful service to the readers. The readers have recognized the service rendered by the staff, and many have taken the trouble to express their appreciation of the help received.

Finance. The general library service has been carried out within the amount appropriated, and the Service Bureau has met its expenses from its earnings.

BOOK NOTICES (January 1-31, 1920)

Unless otherwise specified, books in this list have been presented by the publishers. The Society does not assume responsibility for any statements made; these are taken from the preface or the text of the book.

All the books listed may be consulted in the Engineering Societies Library.

APPLIED CALCULUS.

Principles and Applications. Essentials for Students and Engineers. By Robert Gibbes Thomas. 1919. N. Y., D. Van Nostrand Company. 490 pp., 45 exercises, 166 figures, 5 x 7 in., cloth, $3.00.

In this college text-book, the author has aimed to make clear the basic principles of the calculus and to show that fundamental ideas are involved in familiar problems. Effort has been directed toward the attainment of a working and fruitful knowledge of the elements of the subject and an ability to use it efficiently.

ATLAS AMERICA LATINA.

1919. General Drafting Company, Inc., New York. 196 pp., cloth, 11 x 16 in., $20.

The detailed maps which form the most important part of this atlas have been prepared from the best authorities. They

cover Mexico. Central and South America and the West Indies and are drawn to a uniform scale of fifty miles to the inch. Towns, railways, administrative divisions and physical features are clearly shown and a geographic index is provided.

The atlas also contains general maps showing steamship routes, ocean currents, natural vegetation, prevailing winds, summer and winter rainfall and temperatures, principal products, principal minerals and the language divisions of Latin America, as well as charts showing the foreign trade of each country and descriptive articles concerning their possibilities and conditions.

AVIATION. Theorico-Practical Text-book for Students.

By Benjamin M. Carmina, N. Y., The Macmillan Co. 1919. 172 pp., 92 diagrams, table, 8 x 5 in., cloth, $2.

The author discusses the theory of flight and the construction, rigging and maintenance of airplanes, and gives suggestions on flying. The treatment is non-mathematical throughout, but an appendix is included which gives the mathematical analysis of the laws governing flight.

DER BAU DES DIESELMOTORS.

By Kamillo Körner. Berlin, Julius Springer. 1918. 350 pp, 500 diagrams. 11 x 7 in. Cloth, 30 marks.

The present work is devoted to the practical details of Diesel engine construction and omits all discussion of theoretical considerations. The various elements of engines are discussed in detail and examples of the usual designs are given.

CHILTON TRACTOR INDEX. Vol. 3, No. 1. January, 1920.

Philadelphia, Chilton Company. 478 pp., 10 x 7 in., paper, $1.00.

The Tractor Index is a directory of the farm tractor industry of the country, which gives in tabulated form the specifications of the tractors on the market, lists of tractor and power farm machinery manufacturers, makers of parts and accessories and farm trucks. In addition to these directories, the volume includes a collection of data and articles on power farming, farm lighting plants, tractor testing, tractor standards and other topics of interest to users and dealers.

CONTROLLERS FOR ELECTRIC MOTORS.

A Treatise on the Modern Industrial Controller, together with Typical Applications to the Industries. By Henry Duvall James. N. Y., D. Van Nostrand Company. 1919. 354 pp. +43 pp., 259 illus. Cloth. 8 x 5 in. $3.

The aim of this volume, which is based on a series of articles published in the Electric Journal during 1917 and 1918, is to provide students, operating engineers and users of electrical apparatus, with a good general account of industrial controllers and an explanation of their principles of operation.

THE ELEMENTS OF ASTRONOMY FOR SURVEYORS.

By R. W. Chapman. 1919. Lond., Charles Griffin and Co., Ltd., Phila., J. B. Lippincott Company. 247 pp., 56 diagrams, 5 x 7 in., cloth, $1.75.

Although there are several excellent books on surveying that deal more or less thoroughly with astronomical observations, the author of this work believes that there is a need for an elementary work suitable for the student and for the surveyor who is taking up astronomical observation for the first time. The present work is an attempt to provide an elementary exposition, not only of the practical methods of observation and computation, but also of the main principles that must be thoroughly understood if the surveyor is to be master of his profession.

GOVERNORS AND THE GOVERNING OF PRIME MOVERS.

By W. Trinks. N. Y., D. Van Nostrand Co., 1919. 236 pp. + 28 pp., 140 illus., 6 × 9 in., cloth, $3.50.

This volume aims to present the principles and essentials of the subject in such a manner that the reader may be able to judge existing and future types of governors as well as the properties of prime movers with regard to regulation. It has been written to provide a text-book on the general subject of governors and governing, upon which, the author states, there is no book of any consequence in English. A selected bibliography is included.

THE GREAT LAKES RED BOOK.

A list of over 1000 Vessels of the Great Lakes, with the Name of Owner, Captain and Engineer of each Vessel.

Cleveland, The Marine Review, 1919. 159 pp., 5 x 3 in., paper, $1.00.

Gives a list of the fleets upon the Great Lakes as well as owners, captains and engineers. There is also a table showing capacity of ore-carriers and a port directory.

MINING MATHEMATICS SIMPLIFIED.

By James Wardlaw, Sr., Scottdale, Pa. 1919. 189 pp., 7 x 5 in., cloth, $2.50.

This volume gives simple arithmetical solutions for the problems which confront the practical miner. The author is engaged in preparing miners for examinations for certificates as fire bosses, foremen, etc., in the Pennsylvania bituminous coalfield and has written this text for their use.

THE NEW AMERICAN THRIFT.

The Annals of the American Academy of Political and Social Science. Vol. 87, No. 176, January 1920. Philadelphia, Pa. 248 pp., paper, $1.

CONTENTS: Introduction.—Thrift for the individual and the family.—Thrift for the nation.—American needs for capital; typical examples.—Thrift in resources and industry; typical examples.—The investment of savings.—The promotion and practise of thrift in different countries.—Suggestions for promoting thrift.

A symposium by a number of bankers, economists and business men on the desirability of thrift in national and individual life. The problem is broadly presented and discussed in its various phases by experts.

ORGANIZING FOR WORK.

By H. L. Gantt. 1919. N. Y., Harcourt, Brace & Howe. 113 pp. Cloth. 7 x 5 in. $1.25.

Our civilization depends, according to Mr. Gantt, upon the effectiveness with which our combined industrial and business system work, and recent revolutionary attempts to overthrow it are due to the failure of the present system to recognize fully its responsibility to the community. The author believes that there must be a return to the principle that the first aim of business is to render service to the community and that this result can be peacefully obtained by the use of familiar methods, whose use for the purpose he discusses in the present book.

THE PRINCIPLES OF ELECTRICAL ENGINEERING AND THEIR APPLICATION. Vol. 2. Application.

By Gisbert Kapp. N. Y., Longmans, Green & Co.; Lond., 6 x 9 in. Edward Arnold. 1919. 388 pp. Cloth. 173 diag. $6.

The present textbook is intended for all engineering students and also as a handbook for general engineers. For the latter, the author attempts to provide a work which will give him the fundamental principles of the subject and describe their application in practical engineering, without burdening him with minute details of design. It will, the author hopes, enable the general engineer to determine whether and how any particular piece of electrical plant can be used or adapted for a particular purpose.

Volume 1, dealing with Principles, appeared in 1916. The present volume treats of the applications of these principles in electrical machines.

PRINCIPLES OF METALLOGRAPHY.

By Robert S. Williams. N. Y., McGraw-Hill Book Co., Inc.; Lond., Hill Publishing Co., Ltd., 1920. 158 pp. 75 illus., tables, 8 x 5 in., cloth, $2.

This is a brief introduction to the subject written for students of general science or engineering, who do not specialize in metallography but who will use it to a limited extent in connection with their professional work, and for general readers who wish an introduction to more specialized books. Particular attention is given to the applications of metallography.

RADIO ENGINEERING PRINCIPLES.

By Henri Lauer and Harry L. Brown. 1st edition. N. Y., McGraw-Hill Book Co., Inc., Lond., Hill Publishing Co., Ltd., 1920. 300 pp., 241 diag., 6 x 9 in., cloth, $3.50.

This is a general textbook on radio, written to present the extensive developments in the art made during the war. It consequently is largely devoted to the study of the characteristics and use of the three-electrode vacuum tube in radiotelegraphy and radiotelephony. Sufficient attention has, however, been given to the principles involved in older apparatus to meet the requirements of a general textbook.

THE RAILROAD PROBLEM.

The Annals of the American Academy of Political and Social Science. Vol. 86, No. 175. November, 1919. Philadelphia. Paper, 6 x 10 in., 252 pp., $1.

In this collection of articles by various economists, financiers and railroad men, emphasis has been placed on the current issues as to railroad regulation and the participation of labor in railroad management. The major topics discussed are government operation, current proposals for regulation, the unification of terminals and railway efficiency and labor.

SELENIUM CELLS and How They are Made.

Compiled and arranged by Samuel Wein. 1919. N. Y., The Progress Publishing Company. 33 pp., illus., paper, 8 x 6 in., $1.

This pamphlet presents a concise chronological review of the development of the selenium cell. The various types of selenium cells are described, briefly but explicitly, and diagrammatic illustrations of the more important ones are given. The descriptions have been prepared after an examination of the available literature.

SOUTHERN PINE MANUAL.

Standard Wood Construction. 1919. New Orleans, La., Southern Pine Association. 136 pp. + 10 pp., diagrams and tables, 4 x 6 in., cloth, $1.

This small volume is an engineering handbook for engineers, architects and builders. Tables are given showing the dimensions and properties of yellow pine beams and columns and joists, the specifications of various engineering societies, the permitted working stresses adopted by various cities, and miscellaneous tables of use to users of wood in construction.

THE STORY OF ELECTRICITY. Vol. I.

Edited by T. Commerford Martin and Stephen Leidy Coles. 1919. N. Y., The Story of Electricity Company. 661 pp., 11 x 8 in., cloth, $25. for vol. 1 and 2.

The authors of this volume have prepared an account in popular language of the development of the electrical industry, with particular reference to American achievement. After an introductory chapter on the beginnings of electrical science, the invention and growth of the telegraph, telephone, central station, electric railway, etc. are described. Chapters are devoted to the great electrical companies. The various chapters are accompanied by biographical sketches and portraits of engineers of prominence, past and present. Numerous well-selected illustrations add to the value of the work.

A TEXTBOOK OF RAND METALLURGICAL PRACTISE, Vol. 2.

By Ralph Stokes Jas. E. Thomas, G. O. Smart, W. R. Dowling, H. A. White, E. H. Johnson, W. A. Caldecott, A. McA. Johnston and C. O. Schmitt. 2nd edition, revised, 1919, Lond., Charles Griffin & Company, Ltd., 462 pp., 467 illus., cloth, 9 x 6 in., 25 shillings.

This work was prepared in 1911 by a body of technical men actively engaged in current metallurgical practise upon the Witwatersrand, to provide a textbook giving a detailed account of the methods in actual use in that district, both mechanical and chemical.

The present volume, which discusses the design and construction of reduction plants and the transport of materials is by C. O. Schmitt. No radical change in practise has occurred since the publication of the previous edition, but considerable progress in the development of the use of heavy stamps, and tube mills, and a corresponding advance in the methods of classification and amalgamation have been made. This revised edition has been prepared in the light of these improvements.

TEXT-BOOK ON WIRELESS TELEGRAPHY. Vols. 1 and 2.

Vol. 1. General Theory and Practise. Vol. 2. Valves and Valve Apparatus. By Rupert Stanley. New edition in 2 vols. 1919. Lond., N. Y., Longmans, Green & Company. Vol. 1, 470 pp.; Vol. 2, 357 pp. 6 x 9 in. Cloth, $10.

In the preparation of this textbook for the instruction of wireless operators, the author has kept in mind the special needs of those who have had little preliminary knowledge of electrical matters. He has therefore provided the instruction in elementary electricity and magnetism necessary for an understanding of the principles of energy radiation.

Calculations and formulas have been made as simple as possible in the technical portion of the book and the descriptions of apparatus have been restricted to the best modern types.

The present edition has been largely rewritten and rearranged. Much new matter has been included and a second volume, devoted to valves and valve apparatus, has been added.

OBITUARY

WALTER JAMES WARDER, JR., late Electrical Engineer with Roth Bros. & Co., Chicago, Ill., died on January 20, 1920. Mr. Warder, born Aug. 14, 1879, had his technical training in the Lewis Institute, Chicago, where he was a student for three years. His work in the engineering field lay in the design, manufacture, and application of electrical machinery. At first he was connected with the Western Electric Co. as electrical engineer, later with Roth Bros. & Co. as chief engineer, and a Director of the Company. He joined the A. I. E. E. as Associate in 1903, and became a Fellow in 1913.

NATHAN CORNING KINGSBURY, late Vice-President, American Telephone & Telegraph Co., New York, N. Y., died on January 24, 1920. Mr. Kingsbury was born at Mentor, Lake Co., Ohio, on July 29, 1866. His education, including a Classical Course at Oberlin College up to the Senior year, and a Legal Course at Ohio State University, was not technical, except as acquired by experience in the manufacturing business. After leaving college he was for several years in general business management with the Marinette Iron Works Co., Duluth, Minn., then for ten years Counsel for the Jeffrey Mfg. Co. of Columbus, Ohio. During the next two years he was Vice-President and President of the Michigan State Telephone Co., following which he became associated with the American Telephone & Telegraph Co. He has been an Associate of the A. I. E. E. since 1908.

ALBERT C. KNIGHT, of San Francisco, Cal., was seriously injured in a transmission tower accident on December 29, 1919, while in the employ of the Sierra and San Francisco Power Company. His injury resulted in his subsequent death on December 31, 1919. Mr. Knight was born in 1886 in Dayton, Washington. He finished a course in electrical engineering, after which from 1905 until the time of his death he had experience with several electrical companies of Washington, Oregon, and California.

SECTION AND BRANCH MEETINGS

PAST SECTION MEETINGS

Baltimore.—January 16, 1920, Engineers' Club. Subject: "Ship Propulsion." Speaker: Mr. W. E. Thau, Westinghouse Elec. & Mfg. Co. The lecture was illustrated by lantern slides and was followed by a lively discussion. Attendance 75.

Boston.—February 3, 1920, Boston City Club. The meeting was preceded by a dinner. Subject: "Large Turbo-Generator Units from the Operator's Standpoint." Speaker: Mr. Farley Osgood, Public Service Electric Co., Newark, N. J. The discussion was entered into by Messrs. Stahl, Mosher, Damon, Dillon, Rice and Sniffin. Attendance 275.

Cleveland.—January 20, 1920, Nela Park. In response to an invitation from National Lamp Works, members of the Cleveland Section, A. I. E. E., with other members of the Cleveland Engineering Society, gathered in the Cafeteria at Nela Park as their guests. A splendid luncheon was served, followed by talks bearing on Illumination by Messrs. Shenton, Roseburrow and Harrison. Practical demonstrations were given for calculating illumination and selecting the proper lighting units and reflectors for a given condition. Attendance 222.

February 17, 1920, Hotel Statler. Paper: "The Manufacfacture and use of Efficiency Instruments." Author: Mr. J. W. Esterline, President, Esterline Co. With the use of slides Mr. Esterline illustrated very clearly how a curve drawing instrument may be and is being used to find normal and abnormal conditions in production. He also illustrated many uses of graphic instruments of interest to the engineer responsible for the efficient operation of power consuming devices. Attendance 82.

Denver.—January 17, 1920, Shirley Hotel. The meeting was preceded by a dinner. Subject: "From Sugar Beet to Sugar." Speaker: Mr. D. J. Roach, who spoke on the history of the art, developments achieved in the chemical, mechanical and electrical features. The talk was illustrated by lantern slides and samples of the products of the process of sugar makking. A discussion followed which was participated in by two-thirds of those in attendance. Attendance 27.

Detroit-Ann Arbor.—February 20, 1920, Board of Commerce. Joint meeting of Detroit Ann Arbor Section, A. I. E. E., Detroit Engineering Society, and local Section of A. S. M. E., Paper: "Spectacular Illumination." Author: Mr. W. D'A. Ryan. Mr. Ryan's talk was very interesting and the paper was accompanied by interesting illustrations of specific installations. Attendance 300.

Fort Wayne.—January 15, 1920, G. E. Bldg. No. 16-2. Subject: "Johansson Gauging Tools." Speaker: Mr. Ernst Mentor, of the C. E. Johansson, Inc. Mr. Mentor's talk was illustrated with lantern slides and sample equipment. Attendance 145.

Indianapolis-Lafayette.—January 16, 1920, Chamber of Commerce, Indianapolis. Subject: "The Debt of the Automobile to Electricity." Speaker: Mr. Chester S. Ricker, who is widely known in the automobile world and represents the American Automobile Association in Indiana, Chairman of Technical Committee on timing and scoring at the Indianapolis Motor Speedway, author of text books and hand books, and is also a correspondent for American and English trade magazines. Attendance 28.

Ithaca.—January 16, 1920, Franklin Hall, Cornell University, Subject: "Some Electrical Temperature Devices." Speaker Dr. H. A. Clark, Physicist, Technical Department, Taylor Instrument Co. Dr. Clark in his lecture took up the principal thermal devices in which electricity is used, illustrating the fundamental principles by means of lantern slides. He brought with him and had in operation at the lecture, a small electric furnace with automatic temperature control, with a recorder for registering the temperature, and an indicator for showing at a distance whether the temperature is too low, right or too high; also a multiple recorder giving temperature curves from six thermocouples; a frost alarm and an electrically operated distance reading thermometer for use at room temperatures; a Fery total radiation pyrometer in use; an electrically operated automatic temperature control for an annealing oven. Attendance 135.

January 30, 1920, Sibley Dome, Cornell University. Subject: "Automatic Telephones" and "The Operation of Machine switching." Speaker: Mr. C. A. Berry, Central Office Engineer, American Tel. & Tel. Co. Mr. Bery's talk covered a description of the automatic telephone, its uses, its operation and some of the engineering problems involved. He brought with him some switching mechanisms and automatic telephones, which were seen in full operation at the lecture. The talk was illustrated with lantern slides. Attendance 275.

Lynn.—January 21, 1920, Lynn Classical H. S. Illustrated lecture on "The Manufacture of the Incandescent Lamp" by Mr. E. D. Stryker of the Engineering Department of the G. E Co., Nela Park, Cleveland. Attendance 200.

February 4, 1920, G. E. Hall. Subject: "Underground Cables, their Manufacture and Use Under Modern Practice." Speaker: Mr. R. W. Atkinson, Assistant Chief Electrical Engineer of the Standard Underground Cable Co. The lecture was illustrated by lantern slides. Refreshments were served. Attendance 110.

Madison.—January 28, 1920, Soils Bldg., Univ. of Wisconsin. Subject: "The Work of the Forest Products Laboratory." Speaker: Dr. C. P. Winslow, of The Forest Products Laboratory. The speaker gave a talk on the problems the Laboratory had to meet during the war and how they were met. This was followed by a moving picture which illustrated the actual work of the Laboratory. Attendance 18.

Philadelphia.—February 9, 1920, Engineers' Club. Subject: "Recent Developments in Electric Furnace Practice." Speaker: Prof. J. W. Richards, Lehigh University. Discussion by six representatives of manufacturing corporations marketing electric furnaces. Attendance 112.

Pittsburgh.—February 10, 1920, Chamber of Commerce Auditorium. Subject: "Industrial Electric Heating Applied to Medium and Low Temperature Processes." Speaker: Mr. W. S. Scott, Industrial Heating Section, Westinghouse Elec. & Mfg. Co. Attendance 27.

Portland.—January 13, 1920, Multnomah Hotel. Subject: Discussion of Einstein Theory, by Dr. William Conger Morgan, Professor of Chemistry at Reed College. After the meeting there was an informal dance and buffet luncheon. Attendance 125.

February 10, 1920, University Club. Paper: "The Electric Furnace for Brass Melting" by E. L. Kavanaugh, Electrical Engineer, Detroit Electric Furnace Company. The pap r was illustrated with lantern slides and two reels of motion pictures. Refreshments were served after adjournment. Attendance 75.

Rochester.—January 23, 1920. Subject: "Automobile Ignition Systems." Speaker: Mr. A. D. T. Libby, of the Splitdorf Company. Attendance 36.

St. Louis.—January 28, 1920, Union Electric Assembly Hall Subject: "The Technical Story of the Synchronous Con-

verter" Speaker: Mr. B. G. Lamme, Chief Engineer of the Westinghouse Electric & Manufacturing Co. Following the general lines of his paper Mr. Lamme gave some very interesting points in the technical story of the synchronous converter, showing the causes of different developments. Mr. H. W. Eales, Chief Electrical Engineer of the Union Electric Light and Power Company, then brought out the following additional ideas: (1) the d-c. voltage limits the a-c. voltage of synchronous converters; (2) users often specify unreasonable requirements; (3) the size of converters is limited by the area of the d-c. distribution; (4) small automatic substations may use more converters in d-c. distribution. Mr. Val A. Fynn made some remarks on developments in Europe on the same lines as encountered by Mr. Lamme. Talks were also given by Mr. J. L. Hamilton, Mr. A. H. Timmerman, Mr. Clarkson and Mr. Weichel. Mr. Lamme followed, clarifying points raised in the talks of others. Attendance 110.

San Francisco.—January 21, 1920, Engineers Club. Subject: "Electricity in Gold and Silver Mining Industry. Speaker: Mr. B. B. Beckett. Attendance 55.

Schenectady.—January 16, 1920, Edison Club Hall. Subject: "Commission Manager Form of Government. Speaker: Col. H. M. Waite, a former Manager of the City of Dayton. Col. Waite began his address with the discussion of conditions in American municipalities today, the general dissatisfaction which, he declared, was manifested toward the present form of municipal government. He also discussed the various forms of government as tried out in various municipalities in the United States, comparing the relative merits of each and arguing that the Commission Manager form had the most advantages and least disadvantages of them all. Attendance 275.

February 6, 1920, Edison Club Hall. The speaker of the evening was to be Mr. Calvert Townley, President of the Institute on "The Engineer, Employer and Employee," but Mr. Townley was delayed on account of a storm and arrived at the meeting too late to deliver his paper. He therefore gave a brief talk on the present activities in the Institute. While waiting for Mr. Townley's arrival informal talks were delivered as follows: Mr. W. B. Potter on the electric locomotive, covering some of his experiences with the installations now in operation; Mr. C. W. Stone outlined the reasons for the organization and the scope of the American Radio Corporation; Mr. L. T. Robinson discussed the modification of the Standardization Rules of the A. I. E. E. and gave some of the reasons for the changes which have been made; Mr. D. B. Rushmore on Hydroelectric developments. Attendance 90.

Seattle.—January 20, 1920, Arctic Club Assembly. Business meeting, followed by presentation of a paper on: "Electric Welding of Mild Steel With Particular Reference to Shipbuilding" by Professor William Spraragen. The paper described the recent developments in electric welding; the operation of resistance welding and arc welding. Prof. Spraragen explained the advantages of the various kinds of joints having various amounts of bevel on adjoining plates, different sizes of welding rod, etc. The discussion which followed was taken part in by Messrs. Harisberger, Terrell, Quinan, Bessessen, Rockwell, Des Camp, Jefferson and others. Attendance 70.

Toronto.—January 9, 1920, Engineers Club. Business meeting. Attendance 63.

January 30, 1920, Engineers Club. Business meeting, followed by a paper on: "Artificial Power-Transmission Lines" by Dr. A. E. Kennelly. Dr. Kennelly pointed out how little was actually known regarding what is taking place on the wires; therefore models of lines were made. By means of lantern slides Dr. Kennelly showed what he called thumb-nail formulas to take the place of the text book formulas which are pretty hard for the student to understand and interpret. Some interesting pictures were also shown of the artificial lines now in use. Attendance 71.

February 6, 1920, Engineers Club. Business meeting, followed by an interesting talk on "Polyphase Induction Motors" by N. C. Mills. The talk was illustrated by a number of lantern slides showing the various types of motors, coils, etc., and Mr. Mills explained in detail the advantages and disadvantages of the different types of end ring construction used for the rotors of squirrel cage motors, and also touched on the question of the right kind of babbitt for the bearings. Attendance 70.

Utah.—January 29, 1920, Commercial Club. Subject: "Principles of Automatic Operation." Speaker: Mr. Markham Cheever. Mr. Cheever spoke of relation of labor to operation in connection with automatic substations.

Washington.—February 10, 1920, Cosmos Club. Subject: "Electricity and Ship Propulsion." Speaker: Mr. Cheney of the Navy Department. Attendance 120.

PAST BRANCH MEETINGS

University of Arkansas.—January 20, 1920, Y. M. C. A. Hut. General Electric Company film entitled "The Benefactor" was shown. Attendance 46.

Bucknell University.—February 2, 1920, Electrical Laboratory. Demonstration and lecture by Professor Stettler on high tension voltage. Theory of the Tesla Coil. Attendance 55.

University of California.—December 3, 1919, Mechanics Bldg. Subject: "Electric Railways." Speaker: Mr. A. H. Babcock, Chief Electrical Engineer for the Southern Pacific.

January 28, 1920, Mechanics Bldg. Business meeting. Attendance 16.

California Institute of Technology.—January 26, 1920. Paper: "Design and Construction of a Small Electric Furnace" by Messrs. Woodbury and Bissirs. Attendance 18.

February 16, 1920. Papers: "Electricity in the Oil Industry" by G. L. Cory, and "Coal Mining and Electricity" by Prof. G. Forster. Attendance 30.

Clemson Agricultural College.—January 20, 1920, Physics Lecture Room. Subject: "Radio Telegraphy." Speakers: Professors W. E. Speas and W. H. Godfrey. Attendance 61.

February 3, 1920. Subject: "Relays as Applied to Industrial Motors." Discussions by: Messrs. Voight, Ford and Day. "Life of Pupin" by G. F. Ricker; "Current Events" by R. C. Sarratt. Attendance 46.

February 17, 1920. Subject: "Railway Locomotive" by Prof. S. B. Earle. Discussion by L. H. Lachicotte. "Current Events" by J. H. Schroder. Attendance 64.

Lehigh University.—February 12, 1920. Subjects: "Electric Welding" written by D. C. McGalliard, '19, delivered by Homer I. Moll, '19,—"Electrical Engineering in the Steel Mill" by Mr. David M. Petty, Chief Electrical Engineer, Bethlehem Steel Company. Social hour after the business meeting. Attendance 89.

University of Maine.—February 18, 1920, Lord Hall. A paper was read by Mr. Douglass on the "Electrification of Railroads," illustrated by lantern slides. Also short talks were given by Mr. Bisbee on the Harvard Radio School as it was during the war while he was there, and by President Jones on some of the electrical work in a shipyard where he had worked. Attendance 28.

Massachusetts Institute of Technology.—February 5, 1920. Papers: "Sales Engineering" by L. S. Simons, of the Reliance Elec. & Eng. Co.; "French Radio Sets" by D. S. Dellenbaugh, of Elec. Eng. Staff, M. I. T.; "Lighting Systems of Holmesville, N. Y." by D. B. McGuire, '21. Attendance 40.

University of Michigan.—January 21, 1920, Michigan Union. Smoker. Short talks by Professors Parker and Bailey and other members of the faculty. Music. Refreshments. Attendance 105.

School of Engineering of Milwaukee.—December 23, 1919. Subject: "Modern Systems of Transmission and Distribution of Electrical Energy." Speaker: Mr. G. C. Post, Chief Engineer of The Milwaukee Electric Railway & Light Company. Attendance 90.

University of Minnesota.—February 17, 1920, Engineering Building. Dr. G. D. Shepardson, of the Electrical Engineering Department, spoke on some of the early methods of signaling, as well as some of the later developments in radio and telephony. Mr. S. P. Shakleton, of the Development and Research Department of the American Tel. & Tel. Co., gave an interesting illustrated lecture on the work of his company, touching particularly those phases which have to do with long distance telephone lines. Attendance 27.

University of Missouri.—January 19, 1920, Engineering Building. Subjects: "Main Line Electrification" by L. H. Albus; "Economics of Main Electrification" by C. E. Koester. Attendance 20.

February 16, 1920, Engineering Building. Subject: "Electric Welding" by E. W. Kerr. Attendance 57.

Montana State College.—January 21, 1920, Assembly Hall. Moving picture show "Electrification of Milwaukee Railroad." Attendance 67.

University of Nebraska.—February 4, 1920, Physics Building. Mr. John C. Hoge gave an illustrated lecture on the water power possibilities of Nebraska streams, showing several pictures of present developments and of sites that could be developed.

North Carolina State College.—January 15, 1920, Classroom. Business meeting. Attendance 15.

January 19, 1920, Classroom. Business meeting. Attendance 25.

January 22, 1920, Classroom. Business meeting. Attendance 20.

January 30, 1920, Classroom. Subjects: "Progress in the Art of Communication" by G. W. Tiencken; "The New Sunlight Arc" by J. D. Wallace. Attendance 19.

February 3, 1920, Classroom. Business meeting. Attendance 15.

University of North Carolina.—January 19, 1920. Subject: "Wage Payment Systems." Speaker: Professor J. H. Mustard. Attendance 42.

University of Notre Dame.—Inspection tours as follows: January 8, Gary, Ind., Gary Steel Mills; January 9, Chicago, Ill., Power Plants of the Commonwealth Edison Co., and Western Electric Company; January 10, North Western Power Plant and Franklin Avenue Substation. Attendance 19.

January 19, 1920, Engineering Hall. Subject: "Storage Batteries in Trucks." Speaker: R. Hearn. Attendance 25.

Ohio Northern University.—January 28, 1920, Dukes Memorial. Subjects: "The Essex Power Station of the Public Service Co. of New Jersey, by H. D. Rank; "Commercial Motor Testing" by A. M. Rawand. Attendance 35.

Ohio State University.—February 11, 1920, Robinson Laboratory. Business meeting. Attendance 59.

Stanford University.—January 22, 1920, Little Theater, Stanford Univ. General Electric Company's film "The King of the Rails" was shown to a joint meeting of the Branch and the Mechanical Engineering Society. Mr. William Thomson, G. E. Co., spoke on the electrification of the mountain division of the Chicago, Milwaukee and St. Paul Railroad. Attendance 220.

January 29, 1920, Little Theater. Illustrated lecture on "A Vision of the Engineering Development of the West" by Mr. Robert Sibley. Attendance 150.

February 2, 1920, Mech. Engg. Bldg. Subject: "Hydroelectric Power Development." Short talks by different members. Attendance 23.

A. & M. College of Texas.—January 26, 1920, E. E. Bldg. Subjects: "The Generator" by D. V. Thomas; "Electrical Application" by R. D. Blumberg; "Statistics on the Electric Locomotive" by J. C. Horger. Attendance 28.

University of Texas.—January 26, 1920. A paper on "Wireless Communication" was read by the committee in charge of the program; "Development in Wireless Communication by W. L. Cox; "Wireless in the Navy" by J. P. Buchanan; "Wireless Sets as Navigating Instruments" by Clyde Young. Attendance 25.

Virginia Polytechnic Institute.—January 12, 1920. Mr. B. J. Beitman gave an interesting talk on "The Balancing of Rotors." Attendance 19.

University of Virginia.—February 4, 1920. Mechanical Laboratory. Lecture by Dr. Edgar, Dept. of Chemistry, on personal experiences of the application of science in the war. Attendance 27.

Washington University.—February 10, 1920. Paper: "Standardization" by Mr. A. L. Timmerman, Vice-President of the Wagner Electric Mfg. Co., of St. Louis, which outlined the progress in standardizing production, processes, material, etc., which has come about in large motor manufacturing plants in the last few years. Attendance 61.

University of Washington.—January 13, 1920, Forestry Hall. Subject: "Applications of Electric Welding." Speaker: Prof. William Spraragen. Attendance 15.

February 3, 1920, Forestry Hall. Subject: "Proposed New 15,000 Volt 3-Phase Transmission Line for the City of Seattle." Speaker: Mr. Glen Smith. Attendance 31.

Yale University.—January 27, 1920, Elec. Engg. Laboratory. Subject: "Present Problems in Electric Railways and Freight Haulage." Speaker: Mr. A. B. Cole, Asst. Mgr., Publicity Dept., Westinghouse Company, Pittsburgh, Pa.

ADDRESSES WANTED

A list of members whose mail has been returned by the postal authorities, is given below, together with the addresses as they now appear in the Institute records. Any member knowing the present address of any of these members is requested to communicate with the Secretary at 33 West 39th Street.

1.—Leonard W. Egan, Elec. Furnace Co., Alliance, Ohio.
2.—John McF. Fisher, Arapoho, Oklahoma.
3. G. Foung, Wedgeway Bldg., Schenectady, N. Y.
4.—J. P. Gailunas, 100½ Van Couver Ave., Detroit, Mich.
5.—Albert Kalin, City Light Dept., Seattle, Washington.
6.—Lincoln Nissley, 1213 Pioneer Bldg., St. Paul, Minn.
7.—George L. Sewell, Porter Bros., Norfolk, Va.
8.—Bertrand Smith, Kellogg Hotel, Kellogg, Idaho.
9.—Wm. A. Street, Gatun, C. Z.
10.—Lieut. W. J. Strieby, 34 Simpson Road, Ardmore, Pa.
11.—Lieut. T. W. Swartz, 53, D. Infantry, Chattanooga, Tenn.
12.—A. S. Touche, 72 West Adams Street, Chicago, Ill.
13.—R. M. Umberger, 504 West King Street, Lancaster, Pa.

ENGINEERING SERVICE BULLETIN

OPPORTUNITIES.—Desirable opportunities for service from responsible sources are announced in this Bulletin, and no charge therefor is made.

SERVICES AVAILABLE.—Under this heading brief announcements (not more than fifty words) will be published without charge to the members. Announcements will not be repeated except upon request received after an interval of three months, during this period names and records will remain in the active files.

NOTE.—All replies to either "Opportunities" or "Services Available" should be addressed to the key number indicated in each case and forwarded to the ENGINEERING SOCIETIES EMPLOYMENT BUREAU, 33 West 39th Street, New York City, the employment clearing house of the National Societies of Civil, Mining, Mechanical and Electrical Engineers.

OPPORTUNITIES

YOUNG ELECTRICAL ENGINEERS for power sales engineering work. Must be able to make own tests and reports, and lighting motor and equipment layouts. Work also includes application of gas to industrial processes, and the supplying of high and low pressure to some sections of the city. Salary $115 per month. Location New York State. Z-237.

ELECTRICAL ENGINEER technical graduate, about 25 years of age, to have charge of all electrical equipment and part of the mechanical equipment of an industrial plant. Location New York City. Z-238.

ELECTRICAL DRAFTSMEN familiar with switchboard and control diagrams; also man for substation and general wiring layouts wanted by large industrial concern in middle west. Reply should state education, qualifications, experience and salary expected and preferably give references. Z-246.

YOUNG ILLUMINATING ENGINEER capable of designing show window and commercial lighting installations; selling experience desirable but by no means essential since the man selected to do designing will be assisted by competent commercial lighting salesmen. Location Tennessee. Z-260.

MAINTENANCE ENGINEERS for A-C. and D-C. motors. Location New York City. Z-261.

ELECTRICAL DESIGNING DRAFTSMAN, preferably one who has had experience in power plant designing. Some experience in transmission line designing desired. Salary $175 per month with the assurance of an increase should the man prove fit for work. Location Washington, D. C. Z-272.

PLANT OR WORKS ENGINEER—Mechanical Engineer with experience as works Engineer or Assistant to Works or Chief Engineer; to assume supervision of mechanics, draftsmen, electricians and general plant maintenance and construction, also generation and distribution of power, etc. Position is with large concern where prospects are good. Experience with chemical or textile plants desirable although not essential. State experience in full, salary desired and when available. Location Cleveland, Ohio. Z-287.

ELECTRICAL DRAFTSMEN familiar with industrial plant design embracing electric light power layouts, underground distribution systems, transformers and rotary convertors substations, and telephone and signal systems. Location New York City. Z-293.

TELEPHONE ENGINEER with some operating experience and experience in the valuation of telephone properties. Salary $3600 per annum. Location Illinois. Z-295.

ELECTRICAL DRAFTSMEN for telephone switchboard drafting department. Telephone experience not necessary. Salary to start per week $24-34. Location Chicago, Ill. Z-303.

TELEPHONE ENGINEERS; men with considerable electrical training, preferably in telephone work. Salary to start per week $26-42. Location Chicago, Ill. Z-305.

MANUFACTURING INVESTIGATORS; should have some technical training and considerable shop experience; must be able to make time studies and plan operations. Salary to start per week $34-40. Location Chicago, Ill. Z-306.

MALE EMPLOYMENT MAN to interview candidates and hire them for shop work. Must have had shop experience and be able to handle men. Location Connecticut. Z-316.

MACHINERY PURCHASING AGENT for a large manufacturing company in the East. Technical graduate not over thirty-five years of age with knowledge of sources of supply and construction of both small and heavy machinery and tools of all descriptions. Knowledge of rubber machinery preferred but not essential. Give references, and salary expected to start. Z-318.

ELECTRICAL LABORATORY INSTRUCTOR at Throop College of Technology beginning Fall term 1920-21. Address applications, Professor Electrical Engineering, Throop College of Technology. Pasadena, California. Z-319.

SEVERAL DRAFTSMEN, all grades, familiar with merchant and naval marine installations. College men with other experience considered. Location Pennsylvania. Z-322.

OPERATING ENGINEER to take charge of an eight-hour shift in a 30,000 kw. Central Station. Young technical man if possible, to handle the system of scientific control which it is hoped to install. Position will pay about $165 per month. The shifts are working 8 hours, and the men have one Sunday off every third week, so that the position really is a little better than the average operating job. Location Pennsylvania. Z-331.

CHIEF DRAFTSMAN who will be in charge of all draftsmen in the civil, mechanical and electrical departments of an industrial concern. Will need to have had broad experience in industrial plant engineering, and be able to assist and direct draftsmen on layouts of mechanical and electrical equipment consisting principally of conveying machinery, milling and mixing equipment layouts, high pressure hydraulic equipment consisting of high pressure pumps, extruders, accumulators, and the pipe lines connecting same, high pressure and low pressure steam lines and equipment, power plant equipment, power generating plants, and general building design work. Location Cleveland, Ohio. Z-335.

COLLEGE GRADUATE IN ELECTRICAL ENGINEERING who has had considerable experience in the practical or operating end of electrical work as applied to industrial plants. Duties will include making up reports, visiting factories to take care of electrical troubles, and revisions and installations of new equipment. Location, Cleveland, Ohio. Z-338.

ELECTRICAL ENGINEER with experience in design of D-C. generators and motors of medium and large size. Must be technical graduate, and have had about five years design experience. Permanent position with opportunity for advancement for qualified designer. In applying, state education and practical experience since graduation. Location Pennsylvania. Z-340.

EASTERN CONCERN opening up complete gear manufacturing department needs services of experienced estimator or engineer familiar with spur, worm and herringbone gear business, and capable of taking care of estimates and correspondence. Location Maryland. Z-341.

SERVICES OF TWO YOUNG ELECTRICAL ENGINEERS wanted; recent technical graduate preferred, for A-C. industrial control design. Splendid opportunity. Write stating education, age, nationality, salary and when available. Location Newark, N. J. Z-342.

MECHANICAL ENGINEER: Well established builder of A-C. and D-C. generators and motors, desire high class man experienced in mechanical design of electrical machinery. Immediate opening. Location Ohio. Z-371.

ASSOCIATE PROFESSOR OF ELECTRICAL ENGINEERING with practical experience in telephone engineering, to have charge of courses in telephony and be able to teach some courses in general electrical engineering. Position open September 1, 1920. Salary about $2700 first year. Location-State College in Middle West. Z-381.

RECENT GRADUATE from some reputable technical school, whose training has been in mechanical or electrical engineering and who would fit into power plant work, covering tests, analysis, design and construction. Location Conn. Z-382.

INDUSTRIAL ENGINEERS; technically trained men to become efficiency and cost experts for wood-working association. Employment by year with expenses paid. Traveling most in Central Western section. Address Thomas D. Perry, Grand Rapids, Mich. Z-385.

CONSTRUCTION ENGINEER preferably of college or technical training with experience in handling of material coming into the construction of power houses and sub-stations along mechanical lines from driving the piling to completing the stacks. Should be conversant with design so as to be able at least to make initial computations to check designs against constructional experience. Organization is such, that man is not only brought closely in contact with design work but is given opportunity to familiarize himself with operating conditions. Location Rhode Island. Z-388.

POWER HOUSE SUPERINTENDENT with a first-class license and acquainted with up-to-date power plant practises, connected with production of steam, electricity and refrigeration. Technical graduate preferred. Location Mass. Z-391.

GRADUATE ELECTRICAL ENGINEER with gas or marine engine experience for electrical house lighting and plant development work. Man 25-30 years of age desired. Location New York City. Z-402.

EXECUTIVE SECRETARY—We have an attractive opening, probably to locate at our Cleveland office, for a technically educated man, preferably between 30 and 35 years old, who has had broad experience in manufacturing business using steel as raw material. Familiarity with cost accounting, sales, statistics and general administrative features of such business essential. Candidates must possess ability to meet and tactfully deal with business executives, and a ready command of written English. In reply state age, college or technical school from which graduated, date and degree, whether married or single, specific, chronological account of business experience, present and expected salary. Scovell, Wellington & Company, Certified Public Accountants and Industrial Engineers, New York, Boston, Springfield, Cleveland, Chicago. Address reply to 110 State St., Boston, Mass. Z-418.

ENGINEER experienced in time study for position in factory manufacturing all kinds of wire for electrical purposes. Location New York State. Z-433.

MECHANICAL AND ELECTRICAL ENGINEER familiar with design and construction of factory power plants, heating systems, and general lighting and power wiring for industrial plants. Work will consist of supervision of design and installation of mechanical and electrical features of industrial plant equipment. Location one of the largest cities of southeastern Canada. Z-442.

MECHANICAL OR ELECTRICAL ENGINEER with good knowledge of general power plant work for board work. Salary $45-50. Location New York City. Z-451.

MECHANICAL AND ELECTRICAL ENGINEER; should be technical graduate; will be required to handle office details in connection with power program. Will work in as assistant to construction engineer. Starting salary approximately $200-250 per month. Location Ohio. Z-457.

ELECTRICAL ENGINEER—college graduate. Should possess good personality, be tactful and able to supervise men. Should be experienced on substation and general power plant work. Starting salary approximately $275 per month. Location Ohio, Z-462.

ELECTRICAL ENGINEER experienced in electrical computations of all kinds, especially of wire and cables. Location New York State. Z-464.

ELECTRICAL ENGINEER; recent graduate for field and testing work. Location New York City. Z-468.

RECENT GRADUATES OF MECHANICAL OR ELECTRICAL ENGINEERING COURSES for engineering work connected with production of electrical and mechanical devices. Send application to Mr. J. C. Wilson, the Cutler Hammer Mfg. Co. Milwaukee. State training, experience in industrial plants, if any, references and other information concerning yourself. Z-476.

GROWING-PROGRESSIVE CORPORATION is prepared to develop, manufacture and market a few additional products, preferably small devices used in electric power plant construction. Will consider adding to its staff, engineer with such devices or ideas so as to assit in their development. Location Pennsylvania. Z-479.

ELECTRICAL DRAFTSMEN with experience along designing of electrical switching equipment, etc. for central stations. Location Wisconsin. Z-480.

DRAFTSMEN WANTED FOR PANAMA CANAL: 2 Electrical Draftsmen, one experienced in underground power distribution and building illumination and one power plant designer. Advise minimum salary will accept. 1 Marine Machinery Draftsman, $208 month. Applicants must be thoroughly experienced in special lines above indicated, American Citizens (final papers) under 50 years of age, in good health. Free steamship transportation from New York or New Orleans, salary beginning date of sailing. Write "Chief of Office, The Panama Canal, Washington, D. C." Z-485.

UNION COLLEGE invites correspondence regarding instructorship opening next school year in the Electrical Engineering Department. Location New York State. Z-495.

CHIEF ENGINEER for power station. Plant comprises 2-1500 kv-a. General Electric horizontal turbines, surface condensers, cooling pond, four Badenhausen boilers, stoker equipment. Type of man required is one who has had operating experience in central station work, capable of moulding and directing his own organization and keeping the plant in good operating condition. Man not over forty-five years of age preferred. Salary not less than $200 per month. Location Ohio. Z-523.

ASSISTANT CHIEF ENGINEER; graduate of good technical institution, who has had at least five years experience in Engineering Department of large manufacturing plant. Must have good executive ability. Location Penn. Z-526.

MANUFACTURING COST MEN. Men with sufficient knowledge of fundamentals of cost keeping to be able to originate cost keeping systems for manufacturing operations and to formulate reports which will bring necessary facts concerning operating and production, etc., to the attention of executives for their guidance, desired. Location Boston, Mass. Z-528.

ELECTRICAL ENGINEER one year out of college for general work in engineering department of large central station. Salary $125 per month. Location vicinity of New York City. Z-535.

SALES ENGINEER AND INSIDE MAN to handle secretarial work, for concern manufacturing outdoor substation equipment for electric power companies. Two openings. Salary about $200 per month. Location Pennsylvania. Z-537. A. & B.

UNIVERSITY OF WISCONSIN, Electrical Engineering Department, desires to appoint an Assistant or Associate Professor of Electrical Engineering qualified to assume charge of the Central Station and Electric Railway Courses. An experienced engineer who has carried on investigative work resulting in contributions to the art is desired. R-2080.

ELECTRICAL ENGINEER experienced in electrical construction and operation including high tension and substation work, switchboards, building wiring, underground installation, etc. Should have experience in cable splicing and be familiar with the installation of synchronous motors of 500 horse power and up, should have knowledge of control panels. Must be able to handle at least 100 men including inspectors. Starting salary approximately $250. per month. Location Ohio. Z-554.

EXCELLENT OPPORTUNITY is open for technically trained man to become associated with prominent engineering organization in capacity of sales engineer. Knowledge of general power plant engineering is essential. Salary will be commensurate with ability. Send photograph together with record of your work. Z-557.

INDUSTRIAL PHYSICISTS. An established research laboratory of well-known manufacturer offers positions to qualified scientific men who have research ability. One or two men of scientific training in physics and experience in research are desired. There is also position open for a physicist with less experience but with creative ability. Working conditions are attractive and positions are permanent. Location Ohio. Z-558.

ENGINEER with creative and analytical ability and pleasing personality is desired by a laboratory interested chiefly in the development of lighting. Some experience in lighting desirable though not essential. Permanent position amid pleasant surroundings awaits one who can qualify. Location Ohio. Z-559.

TECHNICAL GRADUATE in electrical engineering with one or two years practical experience, for position in Engineering Department of large electrical manufacturing concern. First class opportunities for advancement. Location Canada. Z-569.

SERVICES AVAILABLE

Assistant Professor of Electrical Engineering, in one of the strongest engineering schools in the east desires responsible position in industrial field requiring engineering sense and executive ability. Age 36; married; available July 1, 1920. Minimum salary $4000. E-2070.

Manager of Small Manufacturing Concern; graduate E. E. and C. E.; age 29; married; varied experience including 3½ years along lines of production, routing, scheduling, costs, control, etc. E-2071.

Associate Professor of Electrical Engineering at state university of recognized standing desires greater opportunity. Age 34. Thoroughly trained, B. A. and E. E. degrees; excellent practical and teaching experience. Wants more executive responsibility. E-2072.

Electrical Engineer; graduate E. E. 1916; age 27, single, at present in consulting engineering office. Four years' varied experience including two years' G. E. test. Have had accounting and business training. Desires position as electrical engineer or as assistant manager in power plant; prefers West. Best references. Salary $2500. Available on application. E-2073.

Manufacturers.—Expert production executive; age 28, married, available on short notice. Graduate engineer with varied experience in production, valuation and construction fields. Location immaterial. E-2074.

Electrical Executive; with broad practical engineering and manufacturing experience, and two years' teaching experience in charge of electrical engineering department of well known college, wants to re-enter industrial field. University graduate electrical engineer 1908, married, age 35. Possesses initiative, perseverance, common sense, and executive ability. Salary $4000. Available July 1st. E-2075.

Experienced Electrical Engineer, now finishing power station construction of about 100,000 kilowatts, desires responsible position with engineering firm or position of Electrical Engineer or Superintendent of power with public utility or manufacturing company. Fourteen years' experience design, construction and operation of power stations and distribution. Electrical engineer degree. Minimum salary $5000. E-2076.

Fellow of Institute; with fifteen years' consulting and lecturing experience; formerly on faculties of engineering of two leading Universities. Has special knowledge of electric furnaces, power plants and engineering quantities and estimates. Good negotiator of contracts. Would compile bulletins and catalogues, or write artistic advertisements. E-2077.

Executive; age 38, married, twelve years' experience in coast artillery and ordnance holding positions of responsibility involving technical knowledge and executive ability. Desires executive position in eastern United States with live company in manufacturing or business offering opportunity for expansion. Salary $6000. E-2078.

Commercial Manager; Engineer at present actively engaged in new business end for central station company. Capable of taking charge of new business department in city of forty to fifty thousand. Available thirty days' notice. E-2079.

Graduate Engineer; age 44, 22 years' continuous business experience, 14 years as head of own company. Qualified in construction, maintenance and operation of power plants and public utilities. Head of efficiency and industrial engineering unit of army bureau 1918. Five years on roadways, sewerage and drainage systems. Salary $6000. E-2080.

Position in Southern California. Minimum salary $6000. Electrical Engineer, Massachusetts Institute of Technology 1903. One year outside construction; fourteen years in testing, designing, publicity and commercial engineering departments, Westinghouse and General Electric; two years consulting capacity steel plant electrification. Present position excellent. Desire to move family to more equable climate sole reason for change. E-2081.

Technical Graduate with three years' practical experience in power plant and manufacturing, and four years' sales work. Special training as executive in sales work. Position desired where future is limited only by ability. Age 30; location in West. Salary $3600. E-2082.

Electrical Engineer with thirteen years' experience covering plans, estimates and specifications for generating stations, substations, industrial installations, overhead and underground distributing systems, street lighting installations, and general electrical engineering combined with commercial and executive experience, desires position. Age 36. Salary $5000. E-2083.

Representation in Central Europe; Professional engineer, University graduate; age 35; married, Associate Member A. S. C. E., A. S. M. E., A. I. E. E., A. W. W. A.; 15 years successful practise in America and Europe, invites correspondence with firms wishing a first class representative, residing in Prague, Bohemia. E-2084.

Electrical Engineer; with extensive mechanical experience and sales training. Has manufactured and sold storage batteries, automobile electrical equipment and commercial motors and generators. Last two years production manager on fractional h. p. motors. Understands mass production and scientific management methods. Age 42. American; married; excellent physical condition. Eastern location preferred. E-2085.

Electrical-Mechanical Engineer; Professor of railway and electrical engineering, consulting engineer, will be available from the middle of June to the middle of September as expert in design, supervision, test or investigation work in connection with railway, steam and electric power generation and transmission, lighting or industrial problems. E-2086.

Electrical Engineer; age 27, married, desires responsible position, Ontario preferred. 12 years' experience on manufacture installation and operation of power house and substation equipment. Thorough knowledge of all classes of equipment including steel mills and electric furnaces. Salary $2400. E-2087.

Electrical Engineer; 10 years' experience, construction and installation, substation and transmission, both overhead and underground, 10 years in supervisory capacity, minimum salary $3000. can furnish references as to character and ability. E-2088.

Electrical or Plant Engineer; over 10 years' practical experience in manufacturing and industrial plants on design and construction of general equipment. Technical education. Minimum salary $3000 per year. Location preferred, vicinity New York City. E-2089.

Technical Graduate; University of Michigan '16. Associate. 3½ years with large telephone company on outside plant engineering. Age 29 years; married. Good mechanic; familiar with design and cost of all types of pole line transmission. Desires connection with consulting firm, traction or power company. Available on 30 days' notice. E-2090.

Experienced Welding Engineer; electric arc and spot welding, also acetylene welding and cutting. Good executive and organizer, hull and sheet metal draftsman. Desires permanent position to take charge of welding department to produce maximum results. Formerly Assistant-Head Electric Welding, Emergency Fleet Corporation. Age 32, married, best references. E-2091.

Sales Engineer:—live wire; six years experience; technical graduate; age 28, will consider high grade proposition. Expert steam turbine, pump, air compressor, and boiler equipment man. Experience also on cranes, electric motors and generators. Both ship and selling experience. Available on reasonable notice. A-1 reference. E-2093.

Capable-Executive: technical graduate; manufacturing experience of electrical and mechanical nature, consisting of factory work, testing, inspection, supplemented by general and production engineering, desires to connect with manufacturing concern in the east, age 30, married, salary $4500. E-2094.

Head of Department of Electricity and Telephony at well-known correspondence school desires position as Associate Professor of Electrical Engineering. 4 years' experience in field; 6 years' of combined teaching, consulting engineering and executive educational work. Technical graduate, 1910; degree, M. E. Age 34, married. Available on six week's notice. Salary $3000. E-2095.

Electrical Engineering Graduate, completing G. E. test, wishes position in New York City. Preparation, character and recommendations of the best. Prefer work involving power; generation, distribution and application. E-2096.

Electrical Engineer; age 31; married; at present head of department of electrical engineering in college of engineering of recognized standing. Also six years practical engineering experience, including three years with General Electric Company in test and engineering departments. Desires position which affords good opportunity for advancement as engineering ability is proven. E-2092.

MEMBERSHIP — Applications, Elections, Transfers, Etc.

ASSOCIATES ELECTED FEBRUARY 18, 1920

*Abbott, Donald A., Commercial Sales Engineering Dept., General Electric Co., Ft. Wayne, Ind.
*Abreu, C. S., Member of Firm, A. Braga & Co., Rua do Rosario 13-A., Sao Paulo, Brazil, S. A.
*Anderton, Thomas R., Engg. Dept., Brown Cos. Paper Mills, Berlin, N. H.
*Appuhn, William E. F., Instructor in Mathematics, Stevens Inst. of Technology, Hoboken, N. J.; res., 550 State St., Brooklyn, N. Y.
Arnold, Ellis J., Senior Student in Elec. Engineering, University of Michigan; res., 707 Oxford Road, Ann Arbor, Mich.
*Aslanides, D. J., 7 Rue Keumourdji, Pera, Constantinople, Turkey.
*Bach, Roy O., Senior Electrical Engineering Student, Univ. of Washington; res., 4113, 7th Ave. South, Seattle, Wash.
*Baker, Douglas B., Salesman, International Western Electric Co., 195 Broadway, New York, N. Y.
Baker, George C., Asst. to Gen. Foreman of Electric Construction, Brooklyn Edison Co., Brooklyn; res., 1929 Washington Ave., New York, N. Y.
*Ballard, Harold L., Instructor in Elec. Engineering, Univ. of Michigan, 109 New Engineering Bldg., Ann Arbor, Mich.
Ballew, Walter W., Commercial Engineer, Westinghouse Elec. & Mfg. Co., 1333 Candler Bldg., Atlanta, Ga.
Beedenbender, Harry L., Electrical Laboratory Asst., Harbishaw Electric Cable Co., Yonkers, N. Y.
*Benjamin, Abraham S., Electrical Engineer, Morkrum Co.; res., 4841 N. Central Park Ave., Chicago, Ill.
*Billstein, Arthur E. F., Student, Univ. of Pennsylvania, Philadelphia; res., 24th & Crozer Sts., Chester, Pa.
*Birch, Leland W., Electrical Engineer, Phoenix Utility Co., Hartsville, S. C.
Blatchley, Henry, Manufacturing Engineer, Winchester Repeating Arms Co.; res., 12 Prospect Place, New Haven, Conn.
*Blunk, A. Dolf, Street Railway Engineer, Durham Traction Co., Durham, N. C.
Bond, Thomas D., Power Engineer, Charles H. Tenney & Co., 201 Devonshire St., Boston, Mass.
Brackett, William H., Electrical Engineer, Lockwood, Greene & Co. of Canada Ltd., 285 Beaver Hall Hill, Montreal, Que.
*Brinkman, Erwin E., Industrial Research Engineer, Operating Research Bureau, Public Service Bldg., Milwaukee, Wis.
*Brown, Henry Speight, Sub-Lieutenant; Radio Engineer, Dept. of Naval Service, Ottawa, Canada.
Brunson, Lawrence W., Instructor in Elec. Engineering, University of Michigan; res., 836 E. University Ave., Ann Arbor, Mich.
*Burger, Edward J., Proprietor, Universal Storage Battery Equipment Co., 736, 3rd Street, San Bernardino, Cal.
*Cappon, Marvin T., Electrical Draftsman, Shepard Electric Crane & Hoist Co., Montour Falls, N. Y.
*Church, Leroy, Cadet Engineer, Public Service Co. of N. J., Marion Power Station; res., 78 W. Front St., Redbank, N.J.
*Colburn, Wellen H., Sales Engineer, Thomson Electric Welding Co., Lynn; res., 114 Grand Ave., Wollaston, Mass.
*Cowgill, Lester B., Somers, Mont.
*Cox, Carl C., Asst. Engineer, Fort Worth Power & Light Co., Fort Worth, Texas.
*Dart, Harry F., Asst. Principal in Elec. Engineering, International Correspondence Schools; res., 924 Green Ridge St., Scranton, Pa.
Dominick, William G., Transformer Engg. Dept., General Electric Co.; res., 215 Elm St., Pittsfield, Mass.
*Eberhardt, Wallace W., Asst. Engineer, Alabama Power Co., 639 Brown-Marx Bldg., Birmingham, Ala.
*Ekdahl, Edwin A., Asst. Supt. & Engineer, Amos Bird Co., Shanghai, China.
*Eslick, Everett, Industrial Engineering, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 691 Center St., Wilkinsburg, Pa.
Fairman, James F., Instructor in Electrical Engineering, Univ. of Michigan; res., 120 N. Division St., Ann Arbor, Mich.
Fenstermacher, Charles N., Telephone Engineer, Western Electric Co., New York, N. Y.; res., 77 Maolis Ave., Bloomfield, N. J.
Fowler, Clarence B., Telephone Engineer, Western Electric Co.; res., 290 West 12th St., New York, N. Y.
Friis, H. Trap, Research Dept., Western Electric Co., 463 West St., New York, N. Y.
From, Owen C., Circuit Engineer, Western Electric Co.; res., 508 W. 112th St., New York, N. Y.
*Fronmuller, Theodor C., Asst. Electrical Engineer, Pacific Gas & Elec. Co., 445 Sutter St., San Francisco, Cal.
*Gadberry, Joseph L., Electrical Engineer, Dallas Power & Light Co., Interurban Bldg., Dallas, Texas.
Galsterer, Andrew, Substation Operator, United Railroads of San Francisco; res., 1102 Masonic Ave., San Francisco, Cal.
*Gefke, Jerome H., Transmission & Protection Engineer, Wisconsin Telephone Co.; res., 605 Van Buren St., Milwaukee, Wis.
*Gittings, William N., Switchboard Requisition Engineer, General Electric Co.; res., 707 South Ave., Schenectady, N.Y.
Glasser, Charles E., Industrial Control Engg. Dept., General Electric Co., Schenectady, N. Y.
*Goldammer, Charles J., Elkhart Lake, Wis.
Grafing, Fred H., Engineer, Electrical Dept., Brooklyn Rapid Transit System, Brooklyn; res., 117 Seminole St., Neponsit, N. Y.
Halls, Robert A., Elec. Draftsman and Asst. to Field Elec. Engineer, American Railways Co., Witherspoon Bldg., Philadelphia, Pa.
Halporn, Arnold D., Sales Engineer, B. F. Sturtevant Co., 135 N. 3rd St., Philadelphia, Pa.
Hansen, Bert A., Sales Engineer, Cutler-Hammer Mfg. Co., 50 Church St., New York, N. Y.
Harbert, William Henry, Electrical Engineer, Federal Mining & Smelting Co., Hailey, Idaho.
Hasegawa, Keizo, Electrical Engineer of Japanese Government Railways, Metropolitan Bldg., 1 Madison Ave., New York.
*Havens, Charles B., Asst. Electrical Engineer, Mountain States Tel. & Tel. Co.; res., 3605 W. 32nd Ave., Denver, Colo.
Hay, William J., Electrician, Duquesne Light Co.; res., 2827 Webster Ave., Pittsburgh, Pa.
Hempsey, Charles E., Equipment Inspector, The Maintenance Co., New York; res., 560, 11th St., Brooklyn, N. Y.
Henderson, Charles W., Asst. Professor of Electrical Engineering, Syracuse University; res., 712 Livingston Ave., Syracuse, N. Y.
Henderson, Horace W. W., Asst. Civil Engineer , Air Ministry, C. M. E. E. Dept., Air Ministry, 6 Portman Square, London, England.
Hix, Dolph G., Division Equipment Inspector, Western Union Telegraph Co., 800 Transportation Bldg., Atlanta, Ga.
*Hoffman, Edward L., Electrical Engineer, Adams-Beatty-Francois Corp.; res., 5613 Calument Ave., Chicago, Ill.
Hofstetter, Carl F., Designing Engineer, Wagner Electric Mfg. Co.; res., 5339 Vernon Ave., St. Louis, Mo.
Horle, Lawrence C. F., Expert Radio Aide, Navy Department, Washington, D. C.
*Hotchkiss, Fred W., Sales Engineer, Electric Machinery Co., Minneapolis, Minn.
*Hughes, Calvin T., Asst. Electrical Engineer, Connecticut Light & Power Co., Waterbury, Conn.
Hughes, Martin C., Foreman of General Laboratory, Test. Dept., N. Y. Edison Co., New York; res., 14 Cobb Place, Corona, N. Y.
Hulatt, H., Manager of Telegraphs, Grand Trunk Railway, Montreal, Quebec, Canada.
*Hyatt, Sidney M., Engineer, Hydraulic Dept., Allis-Chalmers Mfg. Co., Milwaukee; res., 537 68th Ave., West Allis, Wis.
*Kaufman, George A., Electrical Engineering Asst., Carnegie Steel Co., Munhall; res., 6722 Church St., Ben Avon, Pa.
*Keesling, Hector, Supt., Electrical Construction, Pacific Gas & Electric Co., 445 Sutter St., San Francisco, Cal.
*Kleist, Walter A., Student, Univ. of Washington; res., 4504-16th Ave. N. E., Seattle, Wash.
*Klumbach, Hampton R., Draftsman, Halcomb Steel Co.; res., 606 Walnut Ave., Syracuse, N. Y.
*Koonsman, Harold D., Layout Draftsman, Detroit Edison Co.; res., 181 Commonwealth Ave., Detroit, Mich.
*Kurtz, Edwin B., Asst. Professor of Electrical Engineering, Iowa State College, Ames, Iowa.
Lewis, James Porcher, Alabama Power Co., Birmingham, Ala.
*Locke, Edwin A., Elec. Draftsman & Designer, Charles H. Tenney & Co., Boston; res., 25 Somerset St., Belmont, Mass.

Lubcke, Charles M., Designer, American Nitrogen Products Co., 2215 N. 59th St., Seattle, Wash.
Magee, James F., Chief Electrician, State Homeopathic Hospital, Allentown, Pa.
Maggi, Guy J., Inside Trouble Man, New York Telephone Co.; res., 317 East 89th St., New York, N. Y.
*Mathes, Robert Carl, Engineer in Research Branch, Western Electric Co., 463 West St., New York, N. Y.
Mac Alister, Alexander G., Asst. Estimating Engineer, Philadelphia Electric Co., Philadelphia, Pa.; res., 580 Federal St., Camden, N. J.
McArthur, A. W. C., Cable Electrician, Messrs. W. T. Henley's Telegraph Works, Ltd., N. Woolwich; res., 6 Hereford Road, Wanstead, Eng.
McCartin, James W., Electrical Draftsman, Albert C. Wood, 1203 Stock Exchange Bldg., Philadelphia, Pa.
McClure, Edward W., Switchboard Operator, Oneida Plant, Utah Power & Light Co., Preston, Idaho.
*McDowell, Hamilton E., Electrician, Lehigh Valley Power & Light Co., Allentown; University Club, Bethlehem, Pa.
*McElhose, Irving H., Adirondack Electric Power Corp., Utica; res., 136, 2nd St., Ilion, N. Y.
Merkel, Oswald H., Power Clerk, Ludlow Mfg. Associates, Ludlow, Mass.
*Meyer, Charles C., Student, University of Penn.; res., 49 W. Ashmead Place North, Philadelphia, Pa.
*Miller, Claude A., Supt. of Line Dept., Puget Sound Traction, Light & Power Co.; res., 403 So. 51st St., Tacoma, Wash.
Moore, Austin Wilford, Editor, Testbook Dept., International Correspondence Schools; res., 63 W. Parker St., Scranton, Pa.
Moore, Raymond P., Engineer, Buffalo General Electric Co.; res., 792 Ashland Ave., Buffalo, N. Y.
Moser, Harry W., Electrical Engineer, Plant Engg. Dept., American International Shipbuilding Corp., Hog Island; res., 4521 N. 13th St., Philadelphia, Pa.
*Muelleman, Joseph P., Student, Armour Institute of Technology; res., 1460 S. Jefferson St., Chicago, Ill.
Nairn, John M., Power Salesman, Duquesne Light Co.; res., 1306 Allegheny Ave., N. S. Pittsburgh, Pa.
*Nelson, Embert C., Test Dept., General Electric Co.; res., 159 Barrett St., Schenectady, N. Y.
*Nethercut, Donald W., Distribution Engineer, Richland Public Service Co., 10 So. Park St., Mansfield, Ohio.
*Norman, Earl E., Construction Foreman, General Electric Co., Atlanta, Ga.
Northrop, Howard, Chief Electrician, Jagueyal Factory, Cuba Cane Sugar Corp., Central Jagueyal, Prov. Camaguey, Cuba.
*Novak, Frank L., Asst. to President, Charles Cory & Son, Inc., 290 Hudson St., New York, N. Y.
Oehlschlager, William A., Electrician, Pennsylvania R. R. Co.; res., 41 Prospect St., Trenton, N. J.
*Pelaez C., Ernesto, Laboratory Asst., Willard Storage Battery Co., Cleveland, Ohio; res., Calle de Narino No. 2, Medellin, Colombia, S. A.
*Poe, Charles R., Telephone Engineer, American Tel. & Tel. Co., 195 Broadway, New York, N. Y.
*Pomeroy, William C., Instructor in Physics, Univ. of California; res., 2333 Channing Way, Berkeley, Cal.
Porges, Edward D., Sales Engineer, Federal Sign System, 224 N. Meridian St., Indianapolis, Ind.
Porter, H. L., Dist. Manager, Verne W. Shear & Co., 1202 Illuminating Bldg., Cleveland, Ohio.
*Predock, Norvill H., Engineer, St. Louis Car Co., St. Louis; res., 3101 Walter Ave., Maplewood, Mo.
Rannels, Samuel Clyde, 108 Doyle Ave., Providence, R. I.
*Ross, Russell H., Student, Univ. of Minnesota, Minneapolis; res., 727 East 1st St., Duluth, Minn.
*Rowand, Alfred M., Student, Ohio Northern University; res., 522 N. Johnson St., Ada, Ohio.
*Schlenk, Hugo, Jr., Student, University of Minnesota; res., 312, 18th Ave. S. E., Minneapolis, Minn.
*Schwartz, Emil E., Electrical Inspector, Interborough Rapid Transit Co.; res., 351 E. 72nd St., New York, N. Y.
*Sechrist, Gilbert H., Instructor in Electrical Engineering, Louisiana Industrial Institute, Ruston, La.
*Shaw, Harold N., Electrical Engineer, A. O. Smith Corp.; res., 1466, 27th St., Milwaukee, Wis.
*Smith, Winfred W., Research Investigator, N. J. Zinc Company (of Pa.); res., 552 Franklin Ave., Palmerton, Pa.
*Smithson, Earl W., Duplex Lighting Works, General Electric Co., 6 West 48th St., New York, N. Y.
Smythies, Reginald Eric, General Manager, Lincoln Electric Co. of Canada, Ltd., 1109 Temple Bldg., Toronto, Ont.
*Sporn, Max E., Chief Tester, Small Motor Dept., Crocker-Wheeler Co., Ampere, N. J.; res., 63 Canal St., New York, N. Y.
*Sporn, Philip, Office Engineer, Construction Dept., Consumers Power Co.; res., 212 7th St., Jackson, Mich.
*Stacy, John D., Asst. Engineer, Lightning Arrester Engg. Dept., General Electric Co.; res., 27 Ashley St., Pittsfield, Mass.
Stanford, Leland H., Major, Signal Corps, U. S. A., Dept. Signal Office, Fort San Houston, Texas.
*Storm, Hans O., Student, Leland Stanford Jr. University, Stanford University, Cal.
*Strassner, Frank J., Transmission Engineer, Western Electric Co.; New York, N. Y.; res., 716 Clifton Ave., Newark, N. J.
*Stuart, Virgin N., Valuation Engineer, with F. C. Hamilton, 60 Wall St., New York, N. Y.
Sudderth, D. Glenn, Jr., Sales Engineer, Westinghouse Elec. & Mfg. Co., 1333 Candler Bldg., Atlanta, Ga.
Sumner, William A., Designing Engineer, Westinghouse Elec. & Mfg. Co., E. Pittsburgh; res., 835 Rebecca Ave., Wilkinsburg, Pa.
*Swisher, Arthur W., Chief Supervisor, Stores & Material Control, Div. No. 1, American International Shipbuilding Co., Hog Island, Pa.
Tanner, Edwin L., Electrical Engineer, Columbia Graphophone Mfg. Co.; res., 27 Denver Ave., Bridgeport, Conn.
*Thomas, Milton A., Asst. in Engineering Dept., The Connecticut Light & Power Co.; res., 42 Concord St., Waterbury, Conn.
*Trawick, Henry P., Testing Dept., General Electric Co.; res., 855 Union St., Schenectady, N. Y.
*Utley, Romeyn L., Cadet Engineer, Public Service Railway Co.; res., 107 Halsey St., Newark, N. J.
*Warner, Harry O., Instructor in Charge of Electrical Engg., George Washington University, 2023 G. St. N. W., Washington, D. C.
*Wehle, Paul G., Geographical Secretary, Interchurch World Movement, 894 Broadway, New York; res., 112 Grand Ave., Jamaica, N. Y.
West, Harry R., Instructor in Electrical Engineering, Univ. of Pennsylvania; res., 5114 Spruce St., Philadelphia, Pa.
Whitcomb, Arthur J., Testing Engineer, Steel & Tube Co. of America; res., 11313 Forest Ave., Chicago, Ill.
Whiting, Arthur C., Chief Engineer, Hotel Astor, Broadway & 44th St., New York, N. Y.
Withers, Francis P., Manager, Engineering Dept., Central Electric Company, 316 S. Wells St., Chicago, Ill.
*Whittle, Horace, Engineer, Western Electric Co., 463 West St.; res., 825 W. 179th St., New York, N. Y.
Wipperman, Frederic B., Research Dept., Wagner Electric Mfg. Co., 6400 Plymouth Ave., St. Louis, Mo.
Yost, Charles H., Laboratory Asst., General Electric Co., 309 W. 8th St., Erie, Pa.
Young, Levi F., Asst. Laboratory Foreman, Kansas City Light & Power Co., 2110 Walnut St., Kansas City, Mo.
Zeiger, Louis B., General Foreman, Standardizing Laboratory, Brooklyn Edison Co.; res., 1262, 54th St., Brooklyn, N. Y.
*Zippler, William N., Student, University of Pennsylvania, Philadelphia, Pa.; res., 33 High St., Woodbury, N. J.
Total 139
*Former enrolled student.

ASSOCIATES REELECTED FEBRUARY 18, 1920

Baker, Henry S., In Charge of Detail Apparatus, Ontario Power Co.; res., 52 Main St., Niagara Falls, Ont.
McKibbin, Robert H., Electrical Engineer, Southwest Cotton Co., Phoenix, Arizona.

MEMBERS ELECTED FEBRUARY 18, 1920

Bewlay, Henry F., Designing Engineer, Ideal Electric & Mfg. Co., Mansfield, Ohio.
Hill, Harry Charles, Commercial Engineer, Westinghouse Electric International Co.,Union Bldg., Bund & Canton Road, Shanghai, China.
Jensen, J. L. W. V., Chief Engineer, Copenhagen Telephone Co.; res., Amicisvej 16, Copenhagen V, Denmark.
Juhnke, Paul B., Chief Load Dispatcher, Commonwealth Edison Co.; res., 5403 Lakewood Ave., Chicago, Ill.
Lundell, Carl H., Asst. Engineer, Astoria Iron Works, Astoria; res., 507 East 46th St., North, Portland, Ore.
Walther, Harry L., Division Manager, California-Oregon Power Co., 216 W. Main St., Medford, Ore.

TRANSFERRED FEBRUARY 18, 1920

To Grade of Member

ALDRIDGE, A. P., Engineer-in-charge, Waipori Falls Power Station, Dunedin, N. Z.
BURCHER, REGINALD H., Outside Plant Engineer, American Tel. & Tel. Co., New York, N. Y.
DANE, LOUIS P., Asst. Chief Engineer, Railway & Industrial Engineering Co., Greensburg, Pa.
DAVIDSON, WARD F., Instructor in Electrical Engineering, University of Michigan, Ann Arbor, Mich.
HARDY, NORMAN G., Chief Mechanical and Electrical Engineer, The Arizona Copper Co. Ltd., Clifton, Ariz.
HOGAN, JOHN V. L., Manager, International Radio Telegraph Co., New York, N. Y.
LENNARD, WILLIAM H., Electrical Supt., The Haughton Elevator & Machine Co., Toledo, O.
OAKES, CHARLES E., Associate Electrical Engineer, Bureau of Standards, Washington, D. C.
OWEN, ALEXANDER C., Assistant Electrical Engineer, Public Works Department, Wellington, N. Z.
PIERCE, GUY C., Vice-President and General Manager, Northwestern Electric Co., Portland, Ore.
SIMPSON, FRANK, Manager St. Louis District, Pittsburgh Transformer Co., St. Louis, Mo.
WURTS, THOMAS C., Heavy Traction Section, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

To Grade of Fellow

BALL, JOHN D., Vice-President and Dean, School of Engineering of Milwaukee, Milwaukee, Wis.
GREEN, CHARLES M., Research Laboratory, General Electric Co., Lynn, Mass.

RECOMMENDED FOR TRANSFER

The Board of Examiners, at a meeting held on February 16, 1920, recommended the following members of the Institute for transfer to the grade of membership indicated. Any objection to these transfers should be filed at once with the Secretary.

To Grade of Fellow

BLISS, LOUIS D., President, Bliss Electrical School, Takoma Park, Washington, D. C.
GRAY, CLYDE D., Electrical Engineer, J. G. White Engineering Corp., New York, N. Y.
WALLACE, JOHN N., Engineer in Australasia, Western Electric Co., Ltd., Wellington, N. Z.

To Grade of Member

ACKLAND, EUSTACE W., Managing Director, National Electrical & Engineering Co. Ltd., Wellington, N. Z.
BOYKIN, RICHARD M., Vice-President and General Manager, North Coast Power Co., Portland, Ore.
CANDY, ALBERT M., General Engineer, Westinghouse Electric & Mfg. Co., E. Pittsburgh, Pa.
GASKILL, WALTER W., Consulting and Sales Engineering, Boston, Mass.
GILLESPIE, FONTAINE M., Chief Operating Engineer, Riegos y Fuerza del Ebro, Barcelona, Spain.
GUILFORD, WILLIAM S., Director, Griffin Engineering Co. Ltd., Capetown, S. Africa.
HAYES, CLIFTON R., Engineering Manager, Charles H. Tenney & Co., Boston, Mass.
HENKLE, Joseph C., Supt. Meters & Construction, Portland Railway, Light & Power Co., Portland, Ore.
HOFFMAN, CHARLES B., Assistant Professor of Electrical Engineering, University of Cincinnati, Cincinnati, O.
KARTAK, FRANZ A., Professor of Electrical Engineering, School of Engineering of Milwaukee, Milwaukee, Wis.
LAMB, GILBERT C., Electrical Engineer, Engineering Div., E. I. du Pont de Nemours & Co., Wilmington, Del.
MAVITY, VICTOR T., Electrical Engineer, Braden Copper Co., Rancagua, Chile, S. A.
NOYES, JOHN D., Sales Engineer, Detroit Edison Co., Detroit, Mich.
PECK, EMERSON P., Gen'l Supt., Elec. Dept., Utica Gas & Electric Co., Utica, N. Y.
THOMAS, GEORGE N., Electrical Engineer, Canadian General Electric Co. Ltd., Toronto, Ont.
WERWATH, OSCAR, President, School of Engineering of Milwaukee, Milwaukee, Wis.

APPLICATION FOR ELECTION

Applications have been received by the Secretary from the following candidates for election to membership in the Institute. Unless otherwise indicated, the applicant has applied for admission as an Associate. If the applicant has applied for direct admission to a higher grade than Associate, the grade follows immediately after the name. Any member, objecting to the election of any of these candidates should so inform the Secretary before March 31, 1920.

Adams, Harvey P., McAllen, Texas.
Adams, Howard H., Philadelphia, Pa.
Adams, Myron W., Millbury, Mass.
Aitchison, Willard L., New York, N. Y.
Anderson, E. W., Evanston, Ill.
Anderson, William Kingston, R. I.
Andrews, Fred A., Hoosac Tunnel, Mass.
Antoniono, Caesar, Chicago, Ill.
Arledge, George H., Washington, D. C.
Arnold, Oscar M., New York, N. Y.
Aslaniar, Coffing W., Boston, Mass.
Bailey, George N., Worcester, Mass.
Ball, F. Widmer, Toronto, Ont.
Bangs, Philip C., Atlanta, Ga.
Barcus, Miner, Newark, N. J.
Barden, Harold E., Los Angeles, Cal.
Barnes, Stanley M., Detroit, Mich.
Barney, Howard S., Kennett Square, Pa.
Barrett, Charles E., Louisville, Ky.
Barron, Edward F., New York, N. Y.
Barry, Thomas A., Boston, Mass.
Bayle, Russell M., E. Pittsburgh, Pa.
Beard, Harry F., Hog Island, Pa.
Beechinson, Herbert M., New York, N. Y.
Bender, Louis V., Cambridge, Mass.
Benjamin, Webster W., Boulder, Colo.
Bergen, Harold B., New York, N. Y.
Binder, Albert A., (Member), St. Louis, Mo.
Blackwell, William I., Worcester, Mass.
Bland, Henry, Hawthorne, Illinois
Blair, Wayne C., Kansas City, Missouri.
Blue, Frederick R., Brooklyn, N. Y.
Bodey, Norman A., Reading, Pennsylvania.
Bradley, Francis H., New Haven, Conn.
Bradner, James P., Washington, D. C.
Broe, Edgar P., New York, N. Y.
Broodhun, Carl P., Wilkes-Barre, Pa.
Brooks, Forrest E., New York, N. Y.
Brown, Lewis R., (Member), Newark, N. J.
Brown, Wendell S., (Member), Providence, R. I.
Bryan, Cyril K., Schenectady, N. Y.
Burnett, William, Jr., Frankfort, Ill.
Burrows, Walter G., New York, N. Y.
Carlson, Carl F., Brooklyn, N. Y.
Carnachan, Robert S., Washington, D. C.
Carpenter, Leslie S., New York, N. Y.
Champlin, Franklin J., Pittsfield, Mass.
Chapman, V. J., Schenectady, N. Y.
Chesnut, Edward F., Toronto, Ont.
Chute, Norman T., Hartford, Conn.
Clark, Henry W., Washington, D. C.
Clarke, Albert M., Toronto, Ont.
Cleary, Leo H., Washington, D. C.
Cleary, William J., New York, N. Y.
Clements, Chauncey H., New Haven, Conn.
Cleon, Hyman, Washington, D. C.
Cobb, Cecil C., Oklahoma City, Okla.
Collins, Everett B., Worcester, Mass.
Collins, Raymond P., New Haven, Conn.
Comstock, William W., New York, N. Y.
Conklin, Silas H., Washington, D. C.
Cooper, Geoffrey T., Boston, Mass.
Coupland, Richard C., Gloucester, Mass.
Cowles, Willard B., Meriden, Conn.
Cox, Louis T., New York, N. Y.
Creasey, John W., Kansas City, Mo.

STUDENTS ENROLLED
FEBRUARY 18, 1920

11022 Kennedy, Walter A., Wentworth Institute.
11023 Cook, Lee E., Texas A. & M. College
11024 Way, Howard E., Penn. State College
11025 Mugg, Fred H., Leland Stanford Jr., University
11026 Linn, Frank C., Leland Stanford Jr., University
11027 Browning, Clarence L., Kansas State Agricultural College
11028 Peterson, Robert M., Worcester Polytechnic Institute
11029 Wolking, Clifford G., University of New Mexico
11030 Worthington, Leonard F., Bucknell University
11031 Egner, Milton D. M., Johns Hopkins University
11032 Wagner, Hiram J., Bucknell University
11033 Robbins, James E., Bucknell University
11034 Weaver, Torrence E., Penn. State College
11035 Russell, Howard C., Case School of Applied Science
11036 Churchill, Charles H., Cornell University.
11037 Davis, Rowland F., Cornell University
11038 Bass, Percy B., University of Virginia
11039 Coleman, James O'R., University of Virginia
11040 Wolking, Clifford G., University of New Mexico
11041 Orth, Arthur D., Rose Polytechnic Institute
11042 Bryan, William, Rose Polytechnic Institute
11043 Meadows, William H., Jr., Rose Polytechnic Institute
11044 Stone, Frank M., Rose Polytechnic Institute
11045 Kessler, Harold L., Rose Polytechnic Institute
11046 Heubel, Frank N., Rose Polytechnic Institute
11047 Stevenson, Peter J., Penn. State College
11048 Avrit, Roy C., Oregon State Agricultural College
11049 Doukas, Samuel J., Oregon State Agricultural College
11050 Sherman, Donald C., Ohio Northern University
11051 Gaines, Vincent S., Washington University
11052 Tsu, Fong Chang, Massachusetts Institute of Technology
11053 Martin, Curtis R., University of Minnesota
11054 Miller, Joe D., Lewis Institute
11055 Mangney, Elmer J., University of Minnesota
11056 Kline, Frank W., University of Minnesota
11057 Miller, Andrew, University of Minnesota
11058 Firehammer, Paul B., Tri-State College
11059 Brown, Reu W., Oklahoma A. & M. College
11060 Calame, Carroll E., Oklahoma A. & M. College
11061 Coleman, Lester L., Oklahoma A. & M. College

Total 186

PERSONAL

Robert T. Lozier, Consulting Engineer, announces that he has resumed his Industrial Consultant practise, in room 2636, Woolworth Building, New York, N. Y.

Frederic Nicholas, formerly Contributing Editor of the *Electrical World*, has been appointed Secretary of the Electrical Manufacturers' Council. It is hoped to open permanent offices for the Council in New York as soon as a suitable location can be found.

Murray C. Beebe, formerly Professor of Electrical Engineering at the University of Wisconsin, and recently associated with the Western Electric Company, New York, has resigned to become Chief Engineer of the Wadsworth Watch Case Company, Dayton, Kentucky.

Arthur Raymond Nissar, Professor of Electrical Engineering, Central Technological Institute, Byculla, Bombay, India, is shortly proceeding to Europe on leave. His address there for a period of about six months will be c/o Messrs. Thos. Cook & Son, Ludgate Circus, London, England.

Louis Barnett has accepted the position of Sales Engineer with the Multiple Electric Products Co., Inc. of New York. He is a graduate of the Massachusetts Institute of Technology '09 and for the last ten years has been associated with the American Sugar Refinery of Brooklyn as Departmental Engineer, where he has had wide and varied experience with electrical apparatus.

B. J. Grigsby, Vice-President of the Anderson Electric Specialty Co., announces that the corporate name of this company has been changed to Anderson Electric & Equipment Co. There is no change either in the officers or the company's organization; the change has solely been made to render the corporate name more descriptive of the character of the products manufactured by the company and to eliminate the world "Specialty," which did not properly describe the Anderson lines.

Sergis P. Grace, who has been assistant to the Vice President of the New York Telephone Company, has accepted the position of Assistant to the President of the Standard Chemical Company, Pittsburgh, producers of Radium, Vanadium, and Uranium. Mr. Grace has had a long and varied experience in engineering work, especially in the telephone field, in which he has been since 1896. First with the Detroit Telephone Company, he went in 1898 to New Orleans as chief engineer and operating manager of the Peoples' Telephone Company of New Orleans. Following that work he became connected with the Southwestern Telephone & Telegraph Company, of Texas and Arkansas, which he left to become the chief engineer of the Inter-State Telephone Company of New Jersey. In 1902 he joined the engineering staff of the American Telephone & Telegraph Company, which had charge of the design of all Bell Telephone apparatus and methods throughout the country. Leaving the service of the Bell Telephone system in 1913, he engaged in private engineering work in New York City; but in December, 1915 he became again connected with the Bell Telephone system, which at that time included the New York Telephone Company. In December, 1919 he appeared as a witness for the New York Telephone Company before the New Jersey Commission.

OFFICERS of A. I. E. E. 1919-1920

PRESIDENT.

(Term Expires July 31, 1920)

CALVERT TOWNLEY

JUNIOR PAST-PRESIDENTS.

(Term expires July 31, 1920) E. W. RICE, JR.

(Term expires July 31, 1921) COMFORT A. ADAMS

VICE-PRESIDENTS.

(Terms expire July 31, 1920)

A. M. SCHOEN
C. E. SKINNER
JOHN B. FISKEN
L. R. JORGENSEN
N. A. CARLE
WILLS MACLACHLAN

MANAGERS.

(Terms expire July 31, 1920)
CHARLES S. RUFFNER
CHARLES ROBBINS
E. H. MARTINDALE

(Terms Expire July 31, 1921)
WALTER A. HALL
WILLIAM A. DEL MAR
WILFRED SYKES

(Terms Expire July 31, 1922)
WALTER I. SLICHTER
G. FACCIOLI
FRANK D. NEWBURY

(Terms Expire July 31, 1923)
L. E. IMLAY
F. F. FOWLE
L. F. MOREHOUSE

TREASURER GEORGE A. HAMILTON

SECRETARY F. L. HUTCHINSON

(Term expires July 31, 1920)

HONORARY SECRETARY RALPH W. POPE

DIRECTOR OF THE LIBRARY HARRISON W. CRAVER

GENERAL COUNSEL

PARKER and AARON,
52 Broadway, New York.

JOHN J. CARTY, 1915-16.
H. W. BUCK, 1916-17.
E. W. RICE, JR., 1917-18.
COMFORT A. ADAMS, 1918-19.

*Deceased.

A. I. E. E. COMMITTEES

GENERAL STANDING COMMITTEES

EXECUTIVE COMMITTEE

Calvert Townley, Chairman, 165 Broadway, New York.
N. A. Carle, W. A. Hall, George A. Hamilton,
L. F. Morehouse, W. I. Slichter, C. E. Skinner.

FINANCE COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
W. A. Hall, L. F. Morehouse.

MEETINGS AND PAPERS COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
L. W. Chubb, E. E. F. Creighton, John H. Finney, L. R. Jorgensen.
Chairman of Committee on Technical Activities, the chairmen of all technical committees, and the chairmen of all Sections.

PUBLICATION COMMITTEE

W. I. Slichter, Chairman, Columbia University, New York.
N. A. Carle, Wm. A. Del Mar, F. L. Hutchinson, Harold Pender

BOARD OF EXAMINERS

F. L. Rhodes, Chairman, 195 Broadway, New York.
Murray C. Beebe, H. N. Latey, Wm. S. Murray,
H. H. Norris, E. M. Sawtelle, Clayton H. Sharp,
Wilfred Sykes, H. S. Wynkoop.

SECTIONS COMMITTEE

Walter A. Hall, Chairman, General Electric Co., West Lynn, Mass.
C. Francis Harding, Vice-Chairman, Purdue University, Lafayette, Ind.
F. B. Jewett, H. A. Pratt, J. Lloyd Wayne, 3rd,
and the chairmen of all Institute Sections *ex-officio*.

COMMITTEE ON STUDENT BRANCHES

C. Francis Harding, Chairman, Purdue University, Lafayette, Ind.
Alexander M. Gray, A. C. Lanier, J. C. Parker, Charles F. Scott.

MEMBERSHIP COMMITTEE

R. W. Krass, Chairman, W. E. & M. Co., 165 Broadway, New York City.
Wills Maclachlan, S. C. Medbery, Jr., G. S. Rose, G. E. Stoltz,
and the Chairmen of all Membership Committees of Sections.

PUBLIC POLICY COMMITTEE

H. W. Buck, Chairman, 49 Wall St., New York.
C. A. Adams, N. A. Carle, John W. Lieb,
A. C. Marshall, Wm. McClellan, C. E. Skinner.

LAW COMMITTEE

Samuel Sheldon, Chairman, 198½ Schermerhorn St., Brooklyn, N. Y.
John H. Finney, F. B. Jewett, Charles Robbins,
D. B. Rushmore, Charles A. Terry.

HEADQUARTERS COMMITTEE

N. A. Carle, Chairman, Public Service Electric Co., Newark, N. J.
William A. Del Mar, F. L. Hutchinson.

U. S. NATIONAL COMMITTEE OF INTERNATIONAL ELECTROTECHNICAL COMMISSION

C. O. Mailloux, President, 20 Nassau St., New York.
F. B. Crocker, Vice-President,
A. E. Kennelly, Secretary, Harvard University, Cambridge, Mass.
Comfort A. Adams, B. A. Behrend, James Burke,
John J. Carty, L. W. Chubb, W. A. Del Mar,
Gano Dunn, H. W. Fisher, H. M. Hobart,
Dugald C. Jackson, B. G. Lamme, W. S. Moody,
Charles Robbins, E. B. Rosa, David B. Rushmore,
Charles F. Scott, Clayton H. Sharp, C. E. Skinner,
S. W. Stratton, Elihu Thomson, R. B. Williamson.

COMMITTEE ON SAFETY CODES

Farley Osgood, Chairman, 80 Park Place, Newark, N. J.
J. C. Forsyth, H. B. Gear, H. O. Lacount,
Johnston Livingston, M. G. Lloyd, R. W. E. Moore,
Henry N. Muller, H. R. Sargent, G. A. Sawin,
A. M. Schoen, George F. Sever, H. S. Warren.

COMMITTEE ON CODE OF PRINCIPLES OF PROFESSIONAL CONDUCT

George F. Sever, 4 Divinity Ave., Cambridge, Mass.
C. A. Adams, A. H. Babcock, L. B. Stillwell,
Schuyler Skaats Wheeler.

BOARD'S COMMITTEE ON TECHNICAL ACTIVITIES

Wilfred Sykes, Chairman, Westinghouse Elec. & Mfg. Co., E. Pittsburgh, Pa.
G. Faccioli, W. I. Slichter.

STANDARDS COMMITTEE

L. T. Robinson, Chairman, General Electric Co., Schenectady, N. Y.
E. J. Cheney, Secretary, Public Service Commission, Albany, N. Y.
P. G. Agnew, G. A. Anderegg, Frederick Bedell,
L. F. Blume, James Burke, G. A. Burnham,
P. H. Chase, H. H. Clark, F. P. Cox,
E. B. Craft, W. A. Del Mar, F. M. Farmer,
H. W. Fisher, F. C. Hanker, H. M. Hobart,
H. H. Humphrey, H. D. James, P. Junkersfeld,
A. E. Kennelly, G. L. Knight, R. W. Krass,
C. O. Mailloux, C. S. McDowell, W. L. Merrill,
Taliaferro Milton, L. F. Morehouse, F. D. Newbury,
H. S. Osborne, S. G. Rhodes, Charles Robbins,
R. F. Schuchardt, C. E. Skinner, A. B. Smith,
John B. Taylor, A. H. Timmerman, W. K. Vanderpoel,
R. B. Williamson.

EDISON MEDAL COMMITTEE

Appointed by the President for terms of five years

Term expires July 31, 1920.
Carl Hering, Chairman, Harris J. Ryan, Robert Lindsay.
Term expires July 31, 1921.
W. C. L. Eglin, Bancroft Gherardi, E. W. Rice, Jr.
Term expires July 31, 1922.
Comfort A. Adams, L. A. Ferguson, S. W Stratton.
Term expires July 31, 1923.
Frederick Bedell, L. T. Robinson, Calvert Townley.
Term expires July 31, 1924.
E. D. Adams, H. H. Barnes, B. G. Lamme.

Elected by the Board of Directors from its own membership for terms of two years.

Term expires July 31, 1920.
Charles Robbins, C. E. Skinner, W. I. Slichter.
Term expires July 31, 1921.
G. Faccioli, W. A. Hall, Wilfred Sykes.

Ex-Officio

Calvert Townley, President, George A. Hamilton, Treasurer,
F. L. Hutchinson, Secretary.

SPECIAL COMMITTEE

COMMITTEE ON DEVELOPMENT

Charles F. Scott, Chairman, Sheffield Scientific School, Yale University, New Haven, Conn.

F. F. Brand, Pittsfield, Mass.
J. C. Clark, San Francisco, Cal.
Ira M. Cushing, Boston, Mass.
W. A. Del Mar, New York, N. Y.
H. W. Eales, St. Louis, Mo.
F. R. Ewart, Toronto, Ont.
W. A. Hall, W. Lynn, Mass.
W. F. James, Philadelphia, Pa.
Leslie Killam, Milwaukee, Wis.
P. M. Lincoln, Cleveland, O.
A. S. MacDowell, Rochester, N. Y.
H. T. Plumb, Salt Lake City, Utah.
A. M. Schoen, Atlanta, Ga.
C. H. Schum, Erie, Pa.
Samuel Sheldon, Brooklyn, N. Y.
N. W. Storer, Pittsburgh, Pa.
H. L. Wallau, Cleveland, O.
J. Lloyd Wayne, Indianapolis, Ind.
H. E. Bussey, Atlanta, Ga.
Clem A. Copeland, Los Angeles, Cal.
R. H. Dalgleish, Washington, D. C.
F. G. Dustin, Minneapolis, Minn.
H. S. Evans, Boulder, Colo.
Baxter R. Grier, Gatun, C. Z.
John Harisberger, Seattle, Wash.
V. Karapetoff, Ithaca, N. Y.
J. J. Kline, Fort Wayne, Ind.
Chas. A. Lund, Spokane, Wash.
John C. Parker, Ann Arbor, Mich.
L. T. Robinson, Schenectady, N. Y.
R. F. Schuchardt, Chicago, Ill.
W. D. Scott, Portland, Ore.
G. E. Snider, Toledo, O.
L. E. Underwood, W. Lynn, M ass.
J. W. Watson, Madison, Wis.
J. B. Whitehead, Baltimore, Md.

TECHNICAL COMMITTEES

ECONOMICS OF ELECTRIC SERVICE

C. S. Ruffner, Chairman, 644 Riverside Drive, New York.
H. V. Bozell, John B. Fisken, W. S. Gorsuch, L. G. Ireland, A. H. Kruesi, J. F. Meyer, S. G. Rhodes, Allard Smith, E. H. Sniffen, F. B. Yates.

EDUCATIONAL

J. C. Parker, Chairman, 274 New Engineering Bldg., Ann Arbor, Mich.
C. R. Dooley, F. F. Fowle, Charles S. Howe, C. E. Magnusson, E. B. Merriam, L. F. Morehouse, G. H. Pfeiff, H. W. Price, R. F. Schuchardt, W. I. Slichter, William R. Work.

ELECTRICAL MACHINERY

B. A. Behrend, Chairman, 200 Devonshire St., Boston, Mass.
James Burke, Alexander Churchward, A. M. Dudley, C. E. Eveleth, G. Faccioli, B. G. Lamme, A. C. Lanier, R. B. Williamson.

ELECTROCHEMISTRY AND ELECTROMETALLURGY

F. A. J. FitzGerald, Chairman, FitzGerald Laboratories, Niagara Falls, N. Y.
F. F. Ambuhl, E. R. Berry, Joseph L. Dixon, I. R. Edmands, L. E. Imlay, F. A. Lidbury, W. R. Whitney, J. L. Yardley.

ELECTROPHYSICS

F. W. Peek, Jr., Chairman, General Electric Co., Pittsfield, Mass.
P. G. Agnew, H. D. Arnold, E. F. Burton, L. W. Chubb, J. C. Clark, C. P. Eldred, E. P. Hyde, Chester W. Rice, C. E. Skinner.

INDUSTRIAL AND DOMESTIC POWER

A. G. Pierce, Chairman, 2003 Farmers Bank Bldg., Pittsburgh, Pa.
P. H. Adams, E. V. Buchanan, H. W. Cope, Wm. E. Date, James Dixon, A. M. Dudley, R. H. Goodwillie, H. D. James, W. C. Kalb, R. H. McLain, E. H. Martindale, A. H. Timmerman, L. E. Underwood, H. Weichsel, R. B. Williamson.

INSTRUMENTS AND MEASUREMENTS

S. G. Rhodes, Chairman, 104 E. 32nd St., New York.
C. W. Baker, Wm. M. Bradshaw, H. B. Brooks, F. P. Cox, F. V. Magelhaes, Charles Robbins, Clayton H. Sharp.

IRON AND STEEL INDUSTRY

W. F. James, Chairman, 1442 Widener Building, Philadelphia, Pa.
F. B. Crosby, F. D. Egan, Gordon Fox, Eugene Friedlaender, E. S. Jefferies, W. C. Kennedy, D. M. Petty, Wm. T. Snyder, Wilfred Sykes, R. B. Williamson, Fred H. Woodhull, J. D. Wright.

LIGHTING AND ILLUMINATION

C. E. Clewell, Chairman, University of Pennsylvania, Philadelphia, Pa.
G. N. Chamberlin, J. R. Cravath, Terrell Croft, N. S. Dickinson, Bassett Jones, F. D. Newbury, P. G. Nutting, R. C. Powell, E. B. Rosa, W. D'A. Ryan, W. M. Skiff, G. H. Stickney.

MARINE

Arthur Parker, Chairman, New York Shipbuilding Corp., Camden, N. J.
L. C. Brooks, Secretary, Bethlehem Shipbuilding Corp., Bethlehem, Pa.
R. A. Beekman, Eskil Berg, A. R. Cheyney, Maxwell W. Day, E. G. Gallagher, H. L. Hibbard, W. F. James, C. A. Jones, C. S. McDowell, W. F. Meschenmoser, I. H. Osborne, G. A. Pierce, Jr. J. B. Porter, L. B. Sinclair, H. M. Southgate, Wilfred Sykes, W. E. Thau, A. E. Waller, F. W. Wood.

MINES

W. A. Chandler, Chairman, H. C. Frick Coke Co., Scottsdale, Pa.
R. T. Andrae, F. H. Armstrong, Graham Bright, L. C. Ilsley, R. L. Kingsland, A. B. Kiser, Wills Maclachlan, E. B. Woodward.

POWER STATIONS

Philip Torchio, Chairman, 124 E. 15th St., New York.
J. T. Barron, A. E. Bauhan, E. T. Brandon, H. W. Eales, W. L. R. Emmet, W. S. Gorsuch, H. P. Liversidge, I. E. Moultrop, Frank D. Newbury, H. S. Putnam, R. F. Schuchardt, Russell W. Stovel, H. L. Wallau, R. B. Williamson.

PROTECTIVE DEVICES

D. W. Roper, Chairman, 72 West Adams Street, Chicago, Ill.
G. E. Armstrong, P. H. Chase, W. H. Cole, E. E. F. Creighton, H. W. Eales, F. C. Hanker, E. M. Hewlett, F. L. Hunt, P. MacGahan, D. A. McKenzie, A. A. Meyer, L. C. Nicholson, N. L. Pollard, F. E. Ricketts, Charles Robbins, T. C. Taliaferro, H. R. Woodrow.

TELEGRAPHY AND TELEPHONY

Donald McNicol, Chairman, 253 Broadway, New York.
O. B. Blackwell, R. E. Chetwood, E. H. Colpitts, H. W. Drake, W. B. Kouwenhoven, L. F. Morehouse, R. W. Osborne, W. O. Pennell, L. M. Potts, S. A. Rhodes, A. B. Smith, D. M. Therrell, W. H. Winter, D. E. Wiseman.

TRACTION AND TRANSPORTATION

W. S. Murray, Chairman, Room 2800, 165 Broadway, New York.
A. H. Babcock, Reinier Beeuwkes, R. H. Dalgleish, W. G. Gordon, John Murphy, W. B. Potter, Ralph H. Rice, Guy A. Richardson, C. S. Ruffner, N. W. Storer, H. M. Warren.

TRANSMISSION AND DISTRIBUTION

Edward B. Meyer, Chairman, Public Service Electric Co., Newark, N. J.
J. E. Woodbridge, Vice-Chairman, 58 Sutter St. San Francisco, Cal.
R. W. Atkinson, A. O. Austin, Wallace S. Clark, W. H. Cole, A. W. Copley, M. T. Crawford, E. E. F. Creighton, F. E. Ricketts, D. W. Roper, C. S. Ruffner, R. F. Schuchardt, A. E. Silver, W. K. Vanderpoel.

INSTITUTE REPRESENTATIVES

AMERICAN BUREAU OF WELDING

W. L. Merrill.

AMERICAN COMMITTEE ON ELECTROLYSIS

Bion J. Arnold, Wm. S. Murray, F. N. Waterman.

AMERICAN ENGINEERING STANDARDS COMMITTEE

Comfort A. Adams, H. M. Hobart, C. E. Skinner.

AMERICAN YEAR-BOOK ADVISORY BOARD

Edward Caldwell.

BOARD OF TRUSTEES, UNITED ENGINEERING SOCIETY.

L. T. Robinson, Samuel Sheldon, Calvert Townley.

COMMISSION OF WASHINGTON AWARD

John Price Jackson, Charles F. Scott.

COUNCIL OF AMERICAN ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE

H. H. Humphrey, John B. Taylor.

ENGINEERING COUNCIL

Comfort A. Adams, H. W. Buck, N. A. Carle, Charles S. Ruffner, C. E. Skinner.

ENGINEERING FOUNDATION BOARD

Frank B. Jewett, E. W. Rice, Jr.

FRANCO-AMERICAN ENGINEERING COMMITTEE

A. M. Hunt, L. B. Stillwell.

JOHN FRITZ MEDAL BOARD OF AWARD

Comfort A. Adams, H. W. Buck, Calvert Townley, E. W. Rice, Jr.

JOINT COMMITTEE ON ENGINEERING EDUCATION

Charles F. Scott, Samuel Sheldon.

JOINT COMMITTEE ON STANDARD THREAD FOR INSULATORS AND INSULATOR PINS

J. T. Barron.

LIBRARY BOARD OF UNITED ENGINEERING SOCIETY

Edward D. Adams, F. L. Hutchinson, Alfred W. Kiddle, Samuel Sheldon, W. I. Slichter.

NATIONAL FIRE PROTECTION ASSOCIATION, ELECTRICAL COMMITTEE

The chairman of the Institute's Committee on Safety Codes.

NATIONAL JOINT COMMITTEE ON OVERHEAD AND UNDERGROUND LINE CONSTRUCTION.

Farley Osgood, Percy H. Thomas.

NATIONAL RESEARCH COUNCIL, ENGINEERING DIVISION

C. A. Adams, Frank B. Jewett, W. R. Whitney.

NAVAL CONSULTING BOARD

Benjamin G. Lamme, Frank J. Sprague.

SPECIAL JOINT COMMITTEE ON DETERMINATION OF POWER FACTOR IN POLYPHASE CIRCUITS

P. G. Agnew, F. Conrad, F. P. Cox, F. C. Holtz, A. E. Kennelly, Farley Osgood, S. G. Rhodes.

U. S. NATIONAL COMMITTEE OF THE INTERNATIONAL ILLUMINATION COMMISSION

A. E. Kennelly, C. O. Mailloux, Clayton H. Sharp.

LOCAL HONORARY SECRETARIES

Charles le Maistre, 28 Victoria St., London, S. W., England.
Guido Semenza, N. 10 Via S. Radegonda, Milan, Italy.
Robert Julian Scott, Christchurch, New Zealand.
T. P. Strickland, 61 Hunter St., Sydney, N. S. W.
W. G. T. Goodman, Adelaide, South Australia.
James S. Fitzmaurice, Adelaide, South Australia.
L. A. Herdt, McGill Univ., Montreal, Que.
Henry Graftio, Ministry of Ways of Communication, Petrograd, Russia.
A. S. Garfield, 10 Rue de Londres, Paris, France.
Harry Parker Gibbs, Tata Hydroelectric Power Supply Co., Ltd., Bombay, India
John W. Kirkland, Johannesburg, South Africa.

LIST OF SECTIONS

Name	Chairman	Secretary
Atlanta	A. M. Schoen	Thomas C. Taliaferro, S. E. Underwriters Ass'n., Atlanta, Ga.
Baltimore	J. B. Whitehead	L. M. Potts, Industrial Bldg., Baltimore, Md.
Boston	I. E. Moultrop	A. L. Nelson, 387 Washington St., Boston, Mass.
Chicago	A. F. Riggs	A. C. King, 8 So. Dearborn St., Chicago, Ill.
Cleveland	B. W. David	W. D. Smoot, Willard Storage Battery Co., Cleveland, Ohio.
Denver	H. S. Evans	R. B. Bonney, 603 Wyoming Bldg., Denver, Colo.
Detroit-Ann Arbor	J. C. Parker	C. E. Wise, 845 Book Bldg., Detroit, Mich.
Erie	J. C. Barry	P. B. Mansfield, Lawrence Park, Erie, Pa.
Fort Wayne	C. I. Hall	O. B. Rinehart, 1211 W. Jefferson Street, Fort Wayne, Ind.
Indianapolis-Lafayette	J. Lloyd Wayne	D. C. Pyke, Public Service Commission, State House, Indianapolis, Ind.
Ithaca	Alexander M. Gray	John G. Pertsch, Jr., Cornell Univ., Ithaca, N. Y.
Los Angeles	Clem A. Copeland	R. W. Sorensen, Throop College of Technology, Pasadena, Cal.
Lynn	A. K. Warren	Fred E. Ewart, General Electric Company, West Lynn, Mass.
Madison	C. M. Jansky	L. E. A. Kelso, University of Wisconsin, Madison, Wis.
Milwaukee	H. P. Reed	F. J. Mayer, Wisconsin Tel. Co., Milwaukee, Wis.
Minnesota	Fred Dustin	Leo H. Cooper, 200 Builders Exch., Minneapolis, Minn.
New York	H. W. Buck	H. A. Pratt, W. E. & M. Co., 165 Broadway, New York
Panama	Wm. T. O'Connell	M. P. Benninger, Box 174, Balboa Heights, C. Z.
Philadelphia	C. E. Clewell	Ross B. Mateer, Philadelphia Electric Co., 1000 Chestnut St., Philadelphia, Pa.
Pittsburgh	J. G. Carroll	W. L. Shafer, Rm. 522, 416-7th Ave., Pittsburgh, Pa.
Pittsfield	R. E. Wagner	N. F. Hanley, Gen. Elec. Co., Pittsfield, Mass.
Portland, Ore.	E. F. Whitney	W. C. Heston, Portland Ry. Lt. & Pr. Co., Portland, Ore.
Rochester	J. W. Morrison	A. J. Schiefer, Jr., 312 E. & B. Bldg., Rochester, N. Y.
St. Louis	G. A. Waters	Stanley Stokes, Union Elec. Lt. & Pr. Co., St. Louis, Mo.
San Francisco	W. G. Vincent	A. G. Jones, 809 Rialto Building, San Francisco, Cal.
Schenectady	C. S. Van Dyke	L. F. Millham, General Electric Company, Schenectady, N. Y.
Seattle	G. E. Quinan	W. T. Batcheller, Seattle Lt. & Pr. System, Seattle, Wash.
Spokane	J. E. E. Royer	Foster Russell, Symons Bldg., Spokane, Wash.
Toledo	W. A. Hill	Max Neuber, 1257 Fernwood Ave., Toledo, Ohio.
Toronto	Ashton B. Cooper	Daniel M. Fraser, Canadian General Electric Co., Toronto, Ont.
Utah	Markham Cheever	T. A. Purton, General Electric Co., Newhouse Bldg., Salt Lake City, Utah.
Urbana	Morgan Brooks	E. A. Reid, Univ. of Illinois, Urbana, Ill.
Vancouver	R. F. Hayward	T. H. Crosby, Canadian Westinghouse Co., Vancouver, B. C.

ECONOMICAL SUPPLY OF ELECTRIC POWER

(*Continued from page 222.*)

the practicability of electric traction in the zone under contemplation. Table II is indeed a consolidation of interesting facts and I am pleased to note that he arrives at 14,000,000 tons of coal as the amount to be saved by electric traction over-steam which is 2,000,000 tons greater than the figures I have named in an approximate preliminary study of the situation. On the other hand, I think Mr. Potter has been conservative on his estimate regarding the maintenance figures as I believe the savings here will be *much* more rather than "more" in the amount he has named.

An illness has robbed us of Mr. Storer's direct contribution to this paper, but we find his ample support in the traction field by the recent remarks he made before the Western Railroad Club, December 15, 1919. A copy of these remarks is before me. In them he refers to President Townley's paper, read before the Boston Branch of the A. I. E. E. Mr. Townley's paper was epoch-making in its insistance that the railroad man and the electrical man view the railroad problem *together* and not *apart*. Fifteen years of association between the railroad and the electrical man has brought this amalgamation. Mr. C. L. Bardo, General Manager of the New Haven road was one of the first to recognize this necessity. Mr. Bardo recognized that the requirements necessary to efficient operation by electric or steam locomotive were equal—*but opposite*! He observed that an electric engine would haul twice the tonnage for which it was designed and then apparently without rhyme or reason go out of business three weeks later. Whereas, he noted later, if the designed service duty of the electric engine was strictly adhered to it would do its work on half the coal and half the maintenance, and would double or treble its mileage per engine failure.

Quoting from Mr. Storer's paper, "Actually, electricity has been tried in every known kind of railroad service from street railways to high-speed passenger locomotives; from mining locomotives to the heaviest freight locomotives for mountain grade and tunnel service and from switching in the great classification yards to fast freight trains on trans-continental lines. In every case electricity has shown its ability to do its work as well as, and in most cases, it has done better than the steam locomotive has done and would do it."

Mr. Storer closes his paper by saying: "The big question of capacity, fuel conservation, shortage of labor and the improvement of terminals, will exert all the pressure toward electrification that the railways can stand"; all of which points to the necessity of the super-power system which should be ready to contribute its economies to such an end.

High tribute is due Mr. Torchio for his able and intensely interesting contribution regarding the relative value of water versus steam power development. Looking at his study of the situation from conservation standpoint, brings to mind certain remarks made by Mr. Frederick Darlington, whose able services rendered the War Industries Board during the war are well known and appreciated throughout the country. Mr. Darlington said:

"In the central power station business so much of the cost of service goes to pay for invested capital that it is most essential that the interest rates should be kept low which can be done only by making the investment safe, that is; by so regulating rates that principal and interest will be secured. From a national point of view, as effecting the general industrial efficiency of our manufacturing and power-consuming districts, it is relatively unimportant whether the cost of power is one mill or two mills per unit more or less than some established rate, whereas it is of vital importance for the conservation of resources, for economy of production and for general industrial efficiency that the bulk of the power used should be made by central systems as against isolated plants; therefore let us try to get our law-makers and public executives, national, state and municipal, to take the Government point of view, in other words, to think in terms of the war which are also terms of peace from a Government standpoint, and uniformly and rationally to encourage central power development, provide for a just return to capital in electric power business and grant monopolies under regulations that will foster co-ordination and interstate operations."

The point made by Mr. Torchio regarding the decreasing advantages of water powers on rivers without regulative storage, in proportion to their seasonal variation in flow and especially where their energies can be applied only to independent systems carrying low load factor, has been one, and rightly so, to discourage their development.

It is right here where care must now be used to differentiate between the past small and confined conditions as compared with the present large and unconfined conditions. Where, in the past, rivers whose energies were to be applied to a confined system, and whose load curve for one day could be superimposed upon that of the following with near coincidence, were developed for one second-foot per square mile of drainage area, these same rivers, today, are being developed for two, three and even four second-feet per square mile of drainage area, and we have arrived at this condition because of the tremendous progress made in the inter-connections of systems through the means of which extra load capacity and diversity factor are offered. Today water power development is looking quite as much, if not more, for kilowatt-hours as it is for kilowatts, and therefore the more the energy requirement and diversity factor in inter-connected systems, the greater is the opportunity for unregulated streams to pour their kilowatt-hours

into such a composite reservoir of power. This is only saying in another way what Mr. Torchio has already said.

Mr. Torchio's table consolidating a "Review of supply and consumption of coal by classes and territories, and the relation which the potential water powers bear to the amount of coal used in the United States," brings out and confirms my statement that in the east we can never expect a greater contribution from water than 10 per cent of the total power requirement, and it is to the economy of steam produced power that we must earnestly address ourselves. On the other hand, we must be as assiduous in our effort to avail ourselves to a maximum degree of the little that nature has bestowed upon us.

Of great interest comes the check by Mr. Torchio on Mr. Potter's figures of coal to be saved by the electrical operation of the railroads. As stated before, the computed horse power of locomotives in the zone under consideration is 7,000,000. Mr. Torchio shows a total saving of 94,000,000 tons, should the 50,000,000 horse power of steam locomotives in this country be turned into electrical operation. Seven-fiftieths of 94,000,000 would be 13,160,000—a figure lying between my own estimate and that of Mr. Potter's. Again, on the industrial side, Mr. Torchio shows a saving of 61,700,000 tons saved if the present plants in the country, aggregating 25,250,000 horse power, were operated from the lines of high-efficiency central stations. As the computed horse power of the zone under contemplation calls for an aggregate capacity of 10,000,000 horse power, this would accordingly indicate a saving of 10/25 of 61,700,000 or 24,500,000 tons, which added to the above figure, for the railroads, of 13,160,000 tons, makes a total saving of approximately 38,000,000 tons. Both Professor Breckenridge of Yale, Chairman of the Fuel Conservation Committee, Engineering Council, and Director George Otis Smith, head of the department of Geological Survey, have accused me of being too conservative on these savings, and I am glad to see them showing more than less.

We have discussed the generation and utilization of power. The link between its generation and utilization is transmission and distribution. Mr. Percy H. Thomas has contributed a most valuable and illuminating discussion upon this very vital factor of consideration, and it forms a most important part of this presentation. Again we see the objective brought out by Mr. Thomas in that the great base load of the super-power system must be carried by the large, high-economy steam plants supplemented by water power; peak loads and regulative features of the system being taken care of in the main, by "present large generating stations."

Mr. Thomas's comprehensive grasp of the transmission and distribution problem of the super-power zone leaves me with but one recommendation, and that is, your most careful perusal of his paper. The functioning of capacity against inductance in the respective square relation between voltage and current must commend itself to you in the matter of maintaining unity power factor for transmission. Here we see transmission economy maintained and automatic protection against the evil effect of short circuit. A point of almost fascinating interest is the one brought out by Mr. Thomas in the capacity effect on the main line between Boston and Washington to preserve continuity of high power factor and the ability to transfer power north or south without undue loss. The main line will be a veritable static condenser to the whole system, and with such excellent distribution of generating centers, magnetization will provide means of stabilizing and maintaining a constant voltage throughout the whole system.

The simplicity of construction and reduction to a minimum of the switch gear applicable to the 220,000-volt primary transmission, making use to the maximum of present equipment installed, robs the proposed new generating equipment and super lines of much complication and cost.

Mr. Thomas touches on the cost of super-power equipment to the extent of 900,000 kw., this inclusive of generating and transmission equipment up to 700 miles, and names a figure of $150,000,000. Twice that capacity, in combination with the present large plants, would go a long ways toward handling the present industrial and railroad loads in the zone named, Mr. Potter's figures for the railroad requirements being only 750,000 kw.

Mr. Austin's and Mr. Peaslee's contributions regarding the characteristics of line and insulation for high voltage transmission carry conviction. Particularly interesting is Mr. Peaslee's appeal for ruggedness in the insulator, and Mr. Austin's appeal for simplicity of construction throughout, again touching on many points brought out in Mr. Thomas's paper.

Their papers may be interpreted briefly by saying that in the department of insulation, which is second to none in importance to maintain both economy and continuity of operation, the problem is already solved. Indeed, I think that it can be well said that so great are the returns portended by such a proposed system of organized power policy, that like the great bridges built to sustain a high density of transportation, so may these trunk and tie transmission lines be built to carry their great electrical loads. Their very largeness will bring unusual factors of safety both electrical and mechanical.

With these savings in sight, and with the means at hand to effect them, these means being but the placing in operation of intensive practises long tried out and demonstrated as sound in principle—can this nation afford to be classed as one drunk with the wealth of her natural resources, and rolling in a criminal debauch of their treasure? Is it to be the Americanism of the future to permit this intolerable record of waste to go on?

It is hardly within the province of this paper, should the investigation proposed be made and confirm these projected results, to make suggestions regarding the methods of procedure looking toward the financing and construction of the regional plant required. The following points however, are significant:

1. Conservation in fuel, labor and materials reduced to money equivalents represent approximate savings of $300,000,000 per annum.

2. The highest representative engineering talent in the country agrees that the plan is entirely practical.

3. The securities which represent an investment in such a property (said property to be confined to the features of generation and inter-connecting transmissions) whether underwritten by the

a. States, or

b. Federal Government, or

c. Private Interests, or

d. Private Interests guaranteed by the states or Government will carry a low interest by virtue of their great national importance and financing should not be difficult.

4. Our northeast Atlantic seaboard is the natural finishing shop of American industry, populated with skilled labor to which should be available a cheap and reliable power and by it will be secured high-speed production for shipment in American bottoms (our Merchant Marine) to maintain our supremacy in world's trade.

5. Industrial concerns are far behind in their power requirements and a delay in a supply of electrical power to them will force them to resort to and perpetuate the present wasteful method of supplying it by plants built by themselves. The investment necessary to their motor requirements will be gladly borne by them and financed immediately.

6. The railroads in this zone are ready for electrification as only by it will capacity be increased: first by the relief from congestion of coal traffic, and second by higher speed and tractive efforts offered in the use of electrical locomotives, thus obviating the immediate necessity of disproportionate increase in track mileage and equipment. The one alternative or the other must be chosen and the right one is apparent.

The following is a summation of approximate investment cost and return for the super-power zone:

Super-Power System

(a) New machine capacity 2,700,000 kw.
High tension transmission mileage 2100

(b) Unit cost per kw. inclusive of transmission lines, $164

(c) Total cost super power system
2,700,000 × $164 = $442,800,000

Railroads

(a) Present steam horse power 7,000,000

(b) On account increased speed, traction and machine factors 100 per cent steam horse power can be replaced by 80 per cent electrical horse power
7,000,000 × 80 per cent = 5,600,000 h.p.

(c) Cost of electrical locomotives per horse power = $80(high)
5,600,000 × 80 = $448,000,000

(d) 30,000 miles (single track) to be electrified
Cost per mile $7,500
30,000 × 7,500 = $225,000,000

(e) Total cost railroads $673,000,000

Industrial Plants

(a) Total horse power 10,000,000 of which 5,000,000 to be changed to electrical drive.

(b) Cost per horse power inclusive of transformers and local distributions $25

(c) Total cost industrial plants
5,000,000 × $25 = 125,000,000

Total zone investment	$1,240,800,000
Total savings per annum	300,000,000
Average return on investment	24 per cent

1. W. L. R. EMMET

Large Steam Turbines

In discussing the broad expediency of power distribution from central steam stations, it is not necessary to consider the relative merits of turbines of different types. The value of the product of such machines is so great in proportion to their cost that wide variations of efficiency cannot be tolerated, and it may be said that all large turbines are good as compared with other apparatus for obtaining power from fuel. In large turbine units, a variation of 10 per cent in efficiency might justify the scrapping of one machine and the purchase of another, unless the inferior machine could, as is usually the case, be used as a reserve or peak load unit.

The best steam turbine station equipments, operating under favorable conditions, can deliver a horse power hour in the form of electricity with an expenditure of one pound of coal, while four pounds are required to deliver a horse power hour to the drawbar of a good locomotive. The locomotive is further subject to many disadvantages, its fuel supply must be delivered and stored on a relatively small scale in many inconvenient places, and its efficiency is greatly affected by conditions of temperature. Its water supply is also a matter of much trouble and

expense. While the comparison of efficiency between the large power station and the smaller engine or turbine equipment used in small stations and isolated power plants is less striking than that with the locomotives, it is nevertheless highly unfavorable to the small plant, and this is fully demonstrated by the rapid growth in the use of central station power in industrial plants large and small. The important requirements for economical power production in turbine stations are: large and continuous demand, facilities for economical purchase, handling and storage of fuel, and an ample supply of condensing water.

Power delivered near centers of demand where load factor is high has a much higher value than that produced in remote places, that is, it pays to transmit power long distances for occasional or irregular demand, while for large and continuous demand it is profitable to produce it locally.

Our large rivers with their fertile valleys have naturally focused our centers of population and of transportation facilities. They afford the requisites for economical power production, and the lines of railways correspond generally to the natural arteries for its distribution. To accomplish ideal results in power production for general uses over large areas will require broad cooperation, and dependable financial conditions under such franchises as will give reasonable security against political attacks, and which will give scope for the many progressive individual activities which are gradually developing the electrical art and educating the public to its uses.

2. J. F. JOHNSON

Large Steam Turbines

The economy benefits resulting from the proposed consolidation and expansion of electric power production, distribution, and application in a portion of the New England and middle Atlantic section, properly organized and managed, and amply financed, would undoubtedly be very great. Problems involved would require the services of our greatest engineers of finance, organization, distribution, and production, but the writer can see no reason why these should not be satisfactorily and profitably solved.

The problem affecting the steam turbine designer is only a very small portion of the general problem of production. With an electric power generating station, as with a manufacturing establishment, constant output at as nearly as possible full normal capacity is the first requisite to high efficiency or its equivalent, low cost of production.

Studies of the load curves of the various districts served will, no doubt, be made to determine the probable load factor obtainable by the proposed consolidation and expansion.

The greatest amount of saving in cost of production of power is to be made by the discontinuance of the many small and medium sized generating stations, many of which contain apparatus which is either obsolete, incomplete, or uneconomically arranged, and replacing them with large capacity stations designed for maximum reliability and efficiency. This would include the development of available water powers to the maximum degree feasible, and the addition of such steam power stations as would be necessary. Against this saving would, of course, have to be charged the costs and losses incident to the increased distribution system required.

The design of the steam generating stations, such as would be required, should probably not differ materially from those being employed for our largest and most modern stations now building, and their efficiency would not differ materially from those now obtainable except as affected by the higher load factor under which they would operate.

Reliability would, of course, have to be the first aim of the designer, and this requisite would preclude the adoption of experimental apparatus or conditions widely removed from those now used and known to produce satisfactory results.

Generating stations of from 200,000 to 300,000 kw. capacity, employing generating units of from 50,000 to 75,000 kw. capacity, each operating on steam conditions of 300 lb. pressure, 200 deg. fahr. superheat, and 29 in. vacuum referred to a barometer of 30 in., would involve no difficulties of design, construction, nor operation, and from such stations a steam consumption rate of 10 lb. or less per kw-hr. and total station rate of less than $1\frac{1}{2}$ lb. of good quality coal per kw-hr. output should be obtained.

Steam turbines of the multi-cylinder type, similar to those now in use and under construction would possess advantages because of their reliability, efficiency, and flexibility, and also because of their adaptability to other operating conditions, should changes become advisable by reason of further experience or development. Only the high pressure element of a multi-cylinder unit would require alteration to meet such a change of conditions.

3. H. G. REIST

Large A-C. Generators

The following brief discussion has reference to generators needed in a proposed super-power zone extending through the southern part of New England and the southeastern part of New York and Pennsylvania to Washington, D. C. In this area there would naturally be a number of power houses located at points where condensing water was available and where coal could be delivered with the least haulage by rail. Probably most of these power houses would be located on tide-water; others, in the vicinity of the coal mines.

The size of the generating units for such a project will undoubtedly be determined largely by the output

required from individual power houses. Probably there would be at least five generating units in each installation, so that repairs and inspection of the units could be made without much reduction in output at any point. Any reduction in output would have to be supplied from neighboring power houses and the transmission of large masses of power should naturally be avoided to limit the line losses. Nor should there be an excessive number of machines, as this would increase the cost of attendance and installation. A second consideration in determining the size of the units is the economical maximum size of the steam turbine. This subject was discussed at length at a recent meeting of the A. I. E. E. and we may assume that three-phase generators can readily be built for the limiting sizes of the steam units suggested at that time. It seems probable that whatever frequency is selected for this system of distribution, turbines and generators can be supplied to meet the most desirable number of units to be placed in each installation. So many generators of from 30,000 to 50,000 kv-a. are at present in operation, giving satisfactory service, that there need be no hesitancy in considering generators as large as those now in use, or larger.

The potential of these generators should be within the limits of our experience, that is, not above 13,200 volts and preferably lower, if this does not cause inconvenience in the lines leading from the generators to the step-up transformers. The efficiency of large modern generating units is very high. The losses may be expected to be less than 2 per cent of the output of the machine, but even with these small losses, careful attention must be paid to the design of the machine to get satisfactory ventilation so as to keep all parts of the machine reasonably cool. While it is permissible to allow a high temperature on the rotating element, with normal maximum potential of 125 or 250 volts in the windings it is better to restrict the heating in the stationary element to a temperature which will not impair the materials used for insulating the windings. It is recognized that nearly all our flexible insulating materials, such as, paper, cloth, fibre and varnishes, deteriorate at a temperature slightly above 100 deg. cent., with greater or less rapidity. The well-known exception to this rule is mica, but an insulation of mica as applied in electrical machinery, consists of a multitude of thin flakes held together by shellac, or other varnishes which also seal the interstices between the flakes. The electrical resistance of all such varnishes decreases with increase in temperature. With some of these materials, the resistance decreases rapidly at temperatures as low as 75 to 80 deg. cent. Other varnishes, especially some that have been developed in recent years, retain their resistance at considerably higher temperatures. When the subject is considered from all standpoints, it seems undesirable to operate such important machinery at a higher temperature than is allowed by "Class A" insulation in the American Institute Rules. Nor is there much objection to insisting on low temperature on such large machines, since the increase in size and cost of cool machines is negligible as compared with those operating at higher temperatures. Moreover, the mechanical construction should be such as has been tested and found to be reliable. The machines should be designed to have minimum losses and an efficient system of ventilation.

Big generators are cooled by circulating a very large amount of air through the various ducts provided for this purpose in the machine. Any soot or dirt in the air, and the air always carries some of this material, is liable to be deposited on the surfaces of the ventilating ducts and on the exposed surfaces of the coils, thus greatly reducing the efficiency of these surfaces in transmitting the heat to the circulating air. To avoid this deterioration, the air is generally passed through air-cleaning apparatus which removes about 98 per cent of the dirt contents, but even with this cleaning, a considerable amount of dirt will accumulate. An improved method of cooling which has been adopted in a few cases and which has excited the interest of engineers in many other installations, is to enclose the air used in cooling the generator completely, and to re-circulate it, thus not taking in any new air. The circulating air may be cooled by the familiar spray system, but in many cases it is preferable to cool it by a system of radiators, similar to those used on automobiles, only they function to cool the air passing through, instead of cooling the water, as in a motor car. Under certain conditions, the water from the condensed steam may be used as a cooling medium in these radiators. This offers a method of returning part of the heat to the boilers, thus saving a small amount of heat which ordinarily is lost. In this way there is no opportunity for dirt to get into the system.

A closed system of ventilation offers some advantage in extinguishing internal fires which sometimes occur, since it will be possible to retain gases or vapors, which may be used in putting out the fire. It is difficult to do this with the ordinary system of ventilation, since the rapid circulation of the air, of which there is a continued new supply, blows gases out of the machine very rapidly even if enclosing dampers are provided.

On account of the great capacity of the lines in such a large system, there may be some advantage in the use of induction generators. Such machines cannot readily be built in as large sizes as synchronous generators, for the following reasons:

1st. Such machines, having smaller airgaps, are more difficult to ventilate than standard synchronous generators;

2nd. Magnetizing current must be supplied through the armature winding. Therefore, larger current is required in the windings which have to be insulated against the potential of the machine;

3rd. The rotor must be at least partly built of laminated iron, making it impossible to design as stiff a structure as otherwise, thus reducing the critical speed.

Roughly, the size of an induction generator would

probably be from 25 per cent to 30 per cent larger than a synchronous generator and the cost of the machine in proportion. Since the present limit in the design of steam turbine generator sets is due to the turbines and not to the generator, except possibly at 3600 rev. per min., I believe that it is possible to construct induction generators in sizes comparable with the most efficient operation of the turbine, that is, perhaps 20,000 to 25,000 kw. at 1800 revolutions, and 40,000 kw. at 1200 revolutions, for 60-cycle machines. We might assume that the same conditions hold in connection with 25-cycle generators. The efficiency of induction generators would probably be about 1 per cent lower than of synchronous machines.

In the territory to be supplied by the super-power system, power is at present being distributed at a number of frequencies, such as, 25, 40, 60, 62½. I will not attempt to explain the reason for these various frequencies, but no doubt all of them were, or seemed, justified when they were adopted. The present tendency is to standardize 60 cycles, rather than 25 cycles, since the latter cannot be used for lighting and higher frequency gives greater flexibility to the speed of industrial motors. Synchronous converters and motor-generators can more readily be operated from 60 cycles for transforming to direct current, than from 25 cycles, since there is greater choice in the number of poles of the motors. The use of 60 cycles will be a handicap on the transmission line, but probably the line will be sectionalized and very long transmission of power will be the exception, rather than the rule, so that it is possible that these inconveniences may be overcome. Since much machinery has to be replaced, and a large amount of new machinery added, and since the transmission conditions would be better at a frequency lower than 60 cycles, I think it is well to give consideration to the use of 50 cycles on such a project. This frequency is entirely satisfactory for lighting, for commercial motors of all sizes, and for almost all other work, and it would probably be found that ultimately its adoption would be a great advantage to this country commercially, since we should then have what is going to be the world frequency outside of the United States. It might be well to consider the adoption of this frequency now, rather than to let the matter drift and suffer the inconveniences of the continued use of a frequency different from the rest of the world, and ultimately to find it desirable to change our standard at much greater inconvenience and expense than if it were done now.

4. F. D. NEWBURY

Large A-C. Generators

I have given this subject, as presented in Mr. Murray's several letters and in his paper printed in the January A. I. E. E. Journal, careful consideration. I have not been able to give this matter the time it deserves, but trust the following notes will give my point of view, in regard to the generating end of this subject.

The generating element in the proposed Boston-Washington power supply system does not involve anything new or untried. The individual power stations need not, and probably would not, be any larger than stations now in operation, or under construction. Certainly, any probable station involved in carrying out this super-power development could be designed with steam and electric generating units of a size now available.

Suppose we assume a station of 300,000 kw. to 500,000 kw. total capacity. We have available single shaft generating units up to 40,000 kw., with generators of 50,000 kv-a. capacity. The preferred speed for such a unit would be 1200 rev. per min., 60 cycles. Eight to twelve such units would give the assumed total station capacity.

There has also been developed and built triple-shaft cross-compound units of 60,000 kw. Five to eight such units would constitute as large a station as has been suggested. This triple-shaft unit consists of three 20,000 kw. turbine cylinders and generators. There is one high pressure element at 1800 rev. per min. and two low pressure elements at 1200 rev. per min.

All of the generating units referred to are actually conservative in size, and by no means represent the largest units of the speeds in question that could be designed. Information concerning this latter point is given in the recent papers by Eskil Berg and J. L. Johnson, on Steam Turbines, and the writer on the subject of Turbo Generators.

As regards the general subject of the single source of power supply within the zone outlined, I believe that the scheme will have to be developed by building up local central stations. It would seem that the greater part of the gain in economy can be secured if all the power requirements of the given local territory, such as Boston or New York, or Philadelphia, or Baltimore, were supplied from local central station systems. The problem of connecting up such local systems in one super-power scheme and interchanging power in both directions from each local system presents a problem of considerable engineering difficulty, and questionable economic advantage in the present state of the art, and in the present state of central station development. There remains so much to be done in developing each local territory that it would seem wisest to carry this on before attempting linking up several local power systems.

5. W. B. POTTER

Heavy Traction Locomotives

The suggested system of interconnected economic power generation and distribution throughout the proposed super-power zone should adequately and advantageously provide for the electric operation of the

railways within this zone, as well as for the power required for industrial and other purposes. The electrification of these railways would not only insure a substantial reduction in the amount of coal otherwise consumed by the steam locomotives, but would also materially reduce the cost of maintaining the motive power units. Electrification would also provide a more reliable service for all classes of traffic and be a welcome improvement to the traveler as passenger trains would be less frequently late, especially during the winter. The colder the weather the greater is the reserve power of the electric locomotive, which is a much better characteristic than that of the steam locomotive whose power under similar conditions is correspondingly diminished.

There are numerous illustrations of electric operation, which are comparable to the service within the zone under consideration, as well as many other examples of railway electrification throughout the country and abroad, which afford conclusive evidence as to the successful operation of railways with electric power. In fact, a large number of railway electrifications are already embraced within the limits of the proposed zone, and while they do not represent a large proportion of the total mileage, their traffic statistics are available and can readily be studied as a basis for determining the demands of the whole area. A tabulation of these electrifications shows that in this area there are already 380 miles of electric route, embracing 1450 miles of single track and operating 230 electric locomotives and about 1000 motor cars for multiple unit suburban service. A table showing the data of the various roads embraced in this statement, is presented herewith.

TABLE I

Steam Railroad Electrification in the Super-Power Zone

Railroads	Date of electrification	Route Miles	Total mi. of track	No. of locos.	Motor Cars
Balt. & Ohio R. R.	1895	3.6	8.	9	0
L. I. R. R.	1905	88.63	218.	0	477
N. Y. C. & H. R. R. R.	1906	54.00	258.	73	221
W. J. & Seashore R. R.	1906	74.60	150.26	0	109
N. Y. N. H. & H. R. R.	1907	81.63	527.49	106	27
Penn. R. R. (New York)	1910	18.73	97.49	33	8
Boston & Maine R. R.	1911	7.97	21.50	7	0
N. Y. West & Boston	1912	18.23	54.41	1	40
Penn. R. R. (Phila.)	1915	30.5	116.3	0	115
		377.89	1451.45	229	997

In order to obtain a general picture of the railroad traffic which would be affected by the power supply of the super-power zone, we have made a study of the traffic conditions of the territory covered by the zone. In making this study, we have taken data from the Operating Reports of the United States Railroad Administration, extending over the months of 1919, for which comparable figures are available.

The reports of the Railroad Administration do not give separate traffic statistics of the various divisions of the roads embraced in their report, and there is necessarily some uncertainty in estimating the portion of each road and the traffic which would be embraced in the zone. We have tabulated the mileage of those divisions of each road which would presumably be included in the proposed super-power zone, thus determining the percentage of the total mileage of that road lying within the zone. This percentage, or ratio, we have applied to all other data of the road in order to determine the traffic within the zone. This factor, therefore, determines the number of locomotives, the amount of traffic which would be handled electrically instead of by steam, and the tonnage of coal which would be replaced by electric power. In view of these assumptions as to probable area of the super-power zone and the amount of included traffic, the estimate as given can only be an approximation.

As the detailed figures obtained from the Operating Reports do not apply to switching service, we have added 20 per cent to the mileage and tonnage to cover switching service, and as the power requirements per ton-mile for switching are approximately double those for main line service, we have added 40 per cent to cover the coal consumed in the switching.

On this basis we estimate that the railroad traffic in the region covered by the zone can be represented, approximately, by the following table:

TABLE II

Railroad Traffic in the Super-Power Zone (Passenger, Freight and Switching)

Miles of route	12,000
Miles of single track	30,000
Locomotives in service	8,100
Locomotive miles annually	185,000,000
Gross ton miles annually, including main line and switching movements of passenger trains, freight trains and locomotives	170,000,000,000
Tons of coal consume annually	21,000,000

Considering railway electrification broadly throughout the whole country and including only those lines which handle freight and passenger service with electric locomotives, we find there are about 700 electric locomotives operating over 5000 miles of route.

There have been some data published on the results of heavy electrification. The papers to which we would particularly refer are,—

Murray—*Electrification Analyzed and its Practical Application to Trunk Line Roads.* TRANS. A. I. E. E., Vol. XXX, 1911.

Cox—*Electrical Operation of the Butte, Anaconda & Pacific Rwy.* TRANS. A. I. E. E., Vol. XXXIII, Sept. 1914.

Beeuwkes—"Operating Results from the Electrification of the Trunk Line of the C. M. & St. P. Ry." New York Railroad Club—March 16, 1917.

From data available, it would appear that the ton-

miles moved by 6½ pounds of coal in a steam locomotive is approximately equal to that which can be moved by one kilowatt-hour delivered from the power station. Applying this ratio to the last item in Table No. 2, the electric energy required to handle the traffic now handled by the 21,000,000 tons of coal to steam locomotives would be approximately 6,500,000,000 kw-hr.

If we assume 40 watt-hours per ton-mile at the power station, which checks fairly with the records of a mixed service of main line and switching, the total energy for moving the assumed traffic of 170,000,000,000 ton-miles, would be approximately 6,800,000,000 kw-hr.

The actual requirements would, however, be something less. It has been estimated that of all the tonnage moving over the railroad, approximately 12 per cent is taken up with the movement of railroad coal to points of distribution, including a second movement of the same coal in the locomotive tenders. Making an allowance for railroad coal that would still be required, a reduction of 10 per cent would seem a fair estimate. This would correspondingly reduce the yearly power requirements to about 6,000,000,000 kw-hr.

On the basis of probable load factor, this would call for about 1,250,000-kw. of power station equipment.

Conclusions

The conclusions to which this discussion points may be summarized as follows:

1. Of the whole mileage included in the zone, a not very large proportion has been electrified, but main line electrifications now in operation are of sufficient extent and carry tonnage of a character to present data which can be fairly applied to the traffic of the whole district.
2. The traffic within the zone now handled by steam locomotives, if handled electrically, would require an average output of less than 750,000 kw. and if produced entirely by coal-burning electric power stations, would reduce the coal requirement for transportation purposes from 21 million tons to 7 million tons annually.
3. As a certain proportion of the electric power will be produced from hydraulic power stations, this coal requirement will be reduced in proportion as advantage is taken of hydraulic operation.
4. The reduction in cost of maintaining the motive power units would be a large amount which estimated from the locomotive mileage would be in the order of $15,000,000 or more, annually.

6. PHILIP TORCHIO

Role of Water Power and Coal in Super-power Systems

A review of the resources and consumption of coal and the availability of potential water powers in the United States shows that:

1. The *Western States* (Mountain and Pacific) have resources in both coal and water powers to meet indefinitely all their heat and power requirements from either source of supply; the potential water powers alone being large enough to supply over six times all heat and power requirements of 1915.
2. The *other states*, with corresponding heat and power requirements 40 times greater than the Western States, have actually smaller resources in coal and potential water powers, the latter capable of supplying only 8 per cent of their total heat and power requirements. It follows that these states must indefinitely, so far as present human knowledge can foresee, depend upon the use of coal to supply the great bulk of these needs.
3. These states, comparatively so deficient in water powers, consumed in 1915, 528,000,000 tons of coal, about one-half for generating power and one-half for generating heat. They obtained an average efficiency from coal of 5 per cent for the power and 50 per cent for the heat. With present methods of generating power in large, modern central stations the efficiency from coal has been raised to 19 per cent. If all the power had been so generated, the coal saving would have amounted to 185,000,000 tons and the railroads relieved of two thirds of this kind of freight.
4. As the investment cost of a steam plant is only about one-third or one-quarter that of a waterpower development with its transmission connections and steam reserve, and as all other items of investment for the electrification of industrial plants would be the same with power generated either by steam or waterfalls, it follows that every dollar invested in modern steam plants will make available several times more power for the industries than a dollar invested in hydroelectric plants.
5. The offset for the greater overhead charges of hydroelectric power is the saving in coal. The value of this saving will be more or less, according to whether the power is used more or fewer hours every day of the year, and according to the unit price of coal.

Under American conditions, the value of coal saving derived from the use of water power is usually smaller than the difference in overhead charges between steam plants and hydro-plants, except in cases where the power is used continuously every hour of the year, or where the development is connected to a large steam power system which will absorb the entire possible output.

6. With certain industries like electro-chemical processes and the refining of metals, using immense amounts of power continuously, the net cost of hydroelectric power may be considerably less than steam power. There is a great advantage of the whole Nation of devoting as much as possible of the economical water powers, particularly those which are continuous or nearly so and those without regulatory daily storage to intensify the development of these industries which can prosper and render their full benefit to the Nation only under conditions of mass production and most favorable cost of power.
7. In considering the technical and practical fea-

TABLE I—REVIEW OF SUPPLY AND CONSUMPTION OF COAL BY CLASSES AND TERRITORIES, AND

tures of the special problem affecting all the states (exclusive of the Western States) having insufficient potential water power to meet their present and larger future demands, emphasis should be laid on the importance of concentrating the national efforts to secure the largest possible coal savings in co-ordinating modern methods of power generation by steam. Heavy losses would follow a policy of handicapping these developments by any method of water power development which would involve diverting from them the few but most economical large commercial loads, and duplication of plant and substitution of water power, and relegating the steam plants to supply the larger in aggregate but less desirable loads of small commercial and domestic services, with poor utilization of the apparatus on account of low average use of power each day during the year.

Where water powers are used as auxiliaries to general power distribution systems, the most economical conditions for both steam and hydroelectric generation can be fulfilled only where a relatively small proportion of the installed generating capacity is hydroelectric.

8. These conclusions would not apply to the Mountain and Pacific States, where the potential water powers are enormous and of cheaper development and can be depended upon to furnish all local power requirements to a very distant future.

The Utilization of Water Powers as a Measure of Fuel Conservation

The harassing experiences of coal famines have brought forth repeatedly pressure that immediate efforts be directed to the development of the potential water powers of the country. While from the general standpoint of conserving the national coal resources the proposition deserves the most favorable consideration, it is questionable whether quicker and greater results could not be obtained by concentrating the effort upon improving and changing wasteful methods of utilizing coal.

This we shall discuss under two main headings, one surveying the value of "Potential Water Powers as Sources of Saving Fuel;" the other reviewing the "Technical and Practical Features Attending the Utilization of Water Powers;" so that with the aid of the first survey we may arrive at a clear understanding of the logical lines of development and application of potential water powers for the best interests of the Nation.

1. *Potential Water Powers as Sources of Saving Coal.*

In order to appreciate the situation with respect to utilization of waterpower, it may not be amiss to give a bird's-eye view of the supply and consumption of coal by classes and territories and the relation which the potential water powers bear to the amount of coal used in the United States.

In Table I are given, in detail, for the year 1915, the amount of coal consumed under the two main classifications of coal used for:

Primary power	267,000,000	tons:
Heating	275,000,000	"
Total	542,000,000	"

On the basis of estimates made by the United States Geological Survey, and assuming that only about 60 per cent of the total supply will be recoverable, we find that the present supply of coal in the United States, exclusive of Alaska, if consumed at the rate of the 1915 yearly consumption, will last *four thousand years.* The supply in the Western States amounts to about two-thirds of the total of the United States, exclusive of Alaska. The supply in the remaining states, if consumed at the 1915 rate of about 500,000,000 tons per year, would last *one thousand years.* The greatest shortage is in the supply of anthracite, which, if consumed by the anthracite using states at the rate for 1915, would last only *one hundred years.* In any case, therefore, the saving of coal during one generation is not of vital importance.

This disposes of the immediate urgency of considering the conservation of coal per se, at least for the time being, while more pressing subjects demand attention. The vital importance in conserving railroad facilities, need not be considered provided similar coal savings are made by one means or another.

The next point to visualize is the relation between the national coal requirements and the extent to which they could be supplied by the utilization of water powers in place of coal. We find, using Table I, that the 542,000,000 tons of coal produce a total energy figured in terms of million British thermal units of 3,908,320,000 units,

121,620,000 in the Western States, and
3,786,700,000 in all other states.

If all the water powers of the country were utilized they could replace 1,046,000,000 or 27 per cent of the above stated units, of which are available
746,000,000 in the Western States
= 614 per cent of total energy used, and
300,000,000 in all other states
= 8 per cent of total energy used,

The water powers already developed represent 73,900,000 units of which
22,900,000 in the Western States
= 19 per cent of total energy used, and
51,000,000 in all other states
= 1.4 per cent of total energy used,

while the Western States possess large waterpower resources to furnish several times their total power and heat requirements. All other states, are inadequately supplied with water powers. Considering the present commercial limitations of distances for electric power transmission, they could not receive assistance from the excess water powers of the Western States. Their

own water powers, even if fully developed, could not replace more than 8 per cent of the energy required. As about one-sixth of their waterpower is already utilized, the *balance would give only about 6 per cent of their power and heat requirements.* From this arises the necessity of an enlightened national policy encouraging and protecting the efforts of such industries as could be instrumental in realizing savings of coal with all other incidental economies.

While the resources of these states are very great, the coal consumption has been steadily increasing from year to year at the rate of about 10 per cent, and if this increase continues, even the present immense reserve would be exhausted in a small fraction of the 1000 years, without large water power resources to fall back upon in a future not distant as measured by the life of nations.

Coal is used to produce either *primary power* or *heating.*

Referring to Table I we find that all of the coal used in the United Stated approximately *one-half* is for producing power and *one-half* for producing heat.

We find further that in producing power only about 5 per cent of the total energy in the coal is utilized, while in producing heat about 50 per cent is utilized. (These figures do not take into account additional losses met in the transmission and utilization of power or heat, as the case may be).

It is evident from these figures showing the low economy of coal for producing primary power that in this field the utilization of water powers would produce the greatest savings in coal.

The economic value of water powers in conserving coal resources is therefore manifest, but *one of the questions to be considered* is whether at the present time quicker and greater results could not in most instances be obtained by the alternative proposition of securing equivalent or even greater economies through improvements in present methods of generating power or heat from coal.

Analyzing the classified means of power production by services, we find that central stations and electric railways realize the highest efficiency from coal, while all other classes of steam power producers obtain from coal about one-half as much as the central stations. Furthermore, with modern equipment the central stations could obtain nearly twice as much work per pound of coal as the present average from their existing equipments. By supplying with electric power all railroads and industries using steam power this could be done, if generated by modern equipment in central stations, for about one-third the present consumption of coal. The total saving would represent 185,500,000 tons of coal, and the railroads would be relieved of two-thirds of this kind of freight.

To realize these coal economies, it would be necessary to make investments for new steam or hydraulic generating equipment to replace the discarded existing steam locomotives on railroads and steam engines in private plants. In all other cases, with the exception of 11,000,000 horse power in existing private plants which already generate electricity for their operation, it would be necessary to introduce a universal electrification of services, substituting electric motors for mechanical drive in plants and electric locomotives on railroads.

In ultimate analysis, each individual case would have to be studied on its economic merits, but, aside from many technical advantages which the electric operation presents over the operation by steam, which advantages may be of greater importance than the mere saving of coal, in general, for a rough approximation, one may assume that a proposition for electrifying an existing steam-driven plant or a steam railroad will be economically advantageous or not according to whether or not the *fuel saved* will *balance the carrying charges of the cost of electrification.* It will appear, therefore, that in general the unit price of fuel will be the fundamental determining factor of the solution. As an illustration, it has been found that in Italy, where the coal price before the war was ten dollars per ton delivered to the locomotive, the saving from electrification of two-track railroads, with electricity at 1 cent per kw-hr., balanced the extra carrying charges of electrification when the roads consumed 700 tons of coal per mile—equivalent to $7000 cost of coal per mile of road.

I repeat that there are many other considerations to take into account in any specific problem, but the broad fundamental principle holds that the unit price of fuel will determine the net economy of transformation from one power service to another of superior fuel economy. While, therefore, by electrification of railroads and manufacturing plants and substitution of modern efficient apparatus in central stations, we could today, reduce the yearly coal consumption for primary power from 267,000,000 tons to 82,000,000—*a saving of* 185,000,000 *tons*—it is doubtful whether the coal saving would balance the carrying charges for the extra investment required.

In different cases the economic advantages would often times be lacking. This would apply particularly to many railroads, but, on the other hand, the centralization of supply for manufacturers and isolated plants, mines, quarries, etc., would in the majority of cases come within economic limits, and the major part of the indicated possible savings for these services of 74,300,000 tons could be realized in a relatively short time. To accomplish this most economically the central station power undertakings already covering the country with a network of transmitting lines, distributing stations and service lines

1. Should further centralize their production and increase the interconnections between their own and neighboring generating plants, and possibly locate new plants in the coal fields or at by-product gas and coke works; and

2. Should install modern generating apparatus to obtain the highest coal efficiency, and operate this new apparatus more or less continuously, reserving the existing less economical equipment for operation during occasional short periods of high demand for power, such as the evening hours of the winter months. In this manner the added modern equipment would not only serve to carry the new load of the industries transferred to central station service, but would also make a *large saving of coal for the existing load of the central stations.*

It is necessary that we fully realize the importance of this double saving from the addition of modern generating apparatus to existing steam central stations and also the fact that if hydraulic power be so utilized as to appropriate the most economical portion of the steam central station load, the operating costs of the remaining load on these stations, which will usually be required to supplement the hydraulic power, would increase perhaps more than the saving due to the lower cost of the hydraulic power. In addition, the new apparatus for a steam station could be located nearer to the customers who are to use the power, thereby saving the cost and losses of long transmission lines, and the safety of operation and reliability of the electric service would be incomparably greater under all conditions of weather or season or possibility of inimical interference with the lines.

In the foregoing we established the facts that:

All potential water powers are insufficient to provide the total heat and power requirements of the Nation;

The shortage is particularly striking in the case of the states east of the Mountain and Pacific States, hence

The railroads and industries of these Eastern States must always depend largely for their power upon coal;

If, in these states, steam central stations are confined mainly to supplementing hydraulic power from extensive hydro-electric systems, their power costs would increase, offsetting the savings from hydraulic power;

If, on the contrary, central station systems, unified on a large scale, a scale commensurate with that which would prevail in the case of hydroelectric systems, were developed with modern apparatus and correlated with new plants at coal fields, and by-product gas and coke works, etc., the savings in coal would in a few years fully equal the savings from the total potential water powers in the states east of the Mountain and Pacific States. Incidentally, these savings could be realized with a considerably smaller outlay of capital and within a shorter time than that required for the hydraulic development. Also, this program would avoid duplication of plants and conserve an important industry, already splendidly organized with plants and trained men, all confirmed in the enthusiastic faith that their work is the most material and influential factor in the upbuilding of the efficiency of the Nation.

In this respect, after all is said and done, one must admit that the men who are accomplishing the most in saving coal are the central station companies with their power engineers and the manufacturing companies with their motor salesmen, who are achieving the real results by substituting the wasteful small plants operating at 5 and 10 lb. of coal per horse power-hour with the central station supply operating at a coal economy to save over two-thirds of the coal for the same service. It may not be amiss to point out that the merits of waterpower or steam power are of only relative importance to a public utility operating under governmental regulation. Once the prices of service are regulated upon the basis of a reasonable return on investment values, it will be found that the relative savings from hydraulic power over steam power are of very small order as affecting the total cost of service to a customer. These small differences, with a unified system of steam-power generation as suggested, would entirely disappear for practically all domestic and manufacturing classes of service. The only possible exception would be for those rare instances where the customer makes use of a constant power almost continuously throughout the year.

This leads us to the study of the relative value of waterpower and coal power according to conditions of use and applications. We shall find, for instance, that for certain products which the Nation needs the producer must make use of cheap, continuous power, as these necessities could not be commercially obtained in competition with the same products obtained by the use of coal or from importation from other countries, except by power at an extremely low cost. These products, necessary to the Nation, consume in bulk enormous amounts of energy continuously throughout the year, and to these necessities it is obvious that hydraulic power could be applied at greater advantage than to almost any other application which does not make a similar large and continuous use of the available waterpower. These technical and practical points are covered in the following second part of this presentation.

II *Technical and Practical Features Attending the Utilization of Water Powers*

In normal times the exploitation of a water power is justifiable only when the expected economic saving equals or exceeds the results that could be obtained from steam power. The saving must also be predicated upon the existence of an assured market for the sale of the hydraulic power developed. In a few instances, hydraulic power has been secured as incidental to improvements in navigable rivers. It is impossible to generalize and give the value resulting from such double utilization, but it may be said that none of these improvements has been economically justifiable purely from the value of the hydroelectric power developed.

In general, the study of a water power development one must consider, besides the costs of the development,

The amount of water flow and its variation at different seasons, and

The maximum possible seasonal and daily utilization of the water powers by the industries to be served.

With the exception of a few rivers, like those fed from the Great Lakes, the water flow and consequently the power available for most of the potential water powers in the United States east of the Western States is very variable and without facilities for building in the mountain regions suitable reservoirs to impound the water

for the low periods. This is practicable only in situations like those existing in the West. On this account, it has been found necessary to install in conjunction with water powers, large auxiliary steam plants to supplement the deficiency of the water power at times of low water flow, except in instances where water powers are used as auxiliaries to steam systems of relatively large capacity.

The second point under consideration, that of daily utilization of the power by the industries served, is very important and is often overlooked by men not familiar with the operation of power plants. Only certain special industries, like electrochemical industries producing aluminum, carborundum, special steels, caustic soda, nitrate, calcium carbide, etc., can use available power continuously every hour of the day and every day of the year. The average power user, on the contrary, utilizes the maximum power for, say, eight hours a day only, and more or less irregularly even for that period, with no use on Sundays, holidays, etc. This characteristic of individual users makes the utilization of the maximum available power very low. By combining a great number of users, all supplied from one power plant, the conditions are ameliorated in respect to the utilization of the maximum power demand upon the central plant, as the resultant maximum demand is considerably less than the sum of the individual demands of every user. This results from the fact that all users do not reach their maximum power demand at the same time. But, notwithstanding this averaging of individual demands upon the central plant, the net utilization of the resultant maximum demand is still about eight hours a day or 2920 hours out of the possible 8760 hours in a year. In the case of water power plants without regulatory daily storage: the unused power between 2920 and 8760 hours in the year is entirely wasted.

Without further emphasizing this point of the poor utilization of the maximum power in communities, it appears that *where continuous water power is available*, the greatest usefulness is derived by applying it first to special industries and processes which require large amounts of electric power and can be operated continuously, or nearly 8760 hours each year, so that the waste through unused power is reduced to a minimum. If that is not possible, then the best means of utilizing the water power to the greatest advantage is to have it exploited by large power undertakings which can either so arrange their operations that they can utilize all the water power for carrying that portion of their load which is nearly constant throughout the year, leaving the heavy season peak loads to be supplied by their reserve steam stations, or can otherwise distribute the electric power over large territories, including cities, mining fields, agricultural sections requiring electric pumping for irrigation and other uses, so that the resultant utilization of the water power distributed over different places and periods of day or season is high, and the waste of unused available waterpower is reduced. This method of exploitation is economically feasible only where the price of coal is relatively high.

In the case of water powers with variable flow, presenting large variations between minimum and maximum available water power, the necessity for extensive operation of auxiliary steam plants greatly reduces the economic value of the hydro development as an independent source of power, a condition which exists with most potential water powers of rivers east of the Pacific States, where impounding of water is usually impracticable. Economic utilization of such water powers is frequently contingent upon their use in connection with steam power systems so large that the water power is a relatively small proportion of the total.

The economic value of a potential water power is calculable by comparing the investment and operating costs of the water development, plus the steam plant reserve when required, with the cost of an equivalent steam plant or plants. If the power is not to be utilized *in situ* and must be transmitted over long-distance transmission lines, the cost of these lines and the cost of their maintenance and operation must be added to the cost of water power.

To visualize the relative values of water powers under different conditions of water flow and utilization of power, we may make a few comparisons to approximately cover conditions existing in different localities. As costs figures for present prices are lacking I have used pre war prices.

To arrive at a basis for comparing costs, we have reviewed several existing hydroelectric developments and found that the costs per *kilowatt maximum* of power development were as follows:

One case—continuous power	= $167
One case—	= $198
One case—non-continuous power	= $188
One case—	= $238
One case—	= $222

The costs of these developments would be materially higher under present prices of labor and materials, but I shall neglect this feature and assume a cost of $180 per kw. maximum—a figure smaller than the average of the above five costs—and also neglect the extra cost for transmission lines where required. We shall also assume the low rate of 8⅓ per cent for interest, taxes and up-keep.

On the other hand, for the cost of steam plants, I shall assume $60 per kw. maximum—as the corresponding cost before the war—and the rate of 11 per cent for interest, taxes and up-keep.

The estimates for six illustrations are based in each case on the development of a 100,000-kw. plant. In the several cases the plant investments were:

Hydro without steam auxiliary.......	$18,000,000
Hydro with 50 per cent steam auxiliary	21,000,000

Hydro with 100 per cent steam auxiliary	24,000,000
All steam	6,000,000

These figures clearly illustrate the point that for the same amount of power the hydroelectric development requires several times the capital outlay of an equivalent steam plant.

From the detailed estimates of power costs I have abstracted the results in the following tables of comparison.

Before proceeding with the presentation of these comparisons, it may perhaps be well to caution the reader that the figures apply to the *increment costs* of securing power from new plants under the conditions given in the assumptions, and would not apply, for instance, to the cost of power from the average steam station operating apparatus considerably more expensive and less efficient than large turbo units of modern design.

It may also not be amiss to state here that the steam central station industry has made almost revolutionary progress in raising the efficiency to a maximum of about 19 per cent of the energy in coal, while older plant and the average isolated plant of today utilize less than 6 per cent. It is also reasonable to expect that, with time, still further progress will be made.

On the other hand, in the case of water powers, hydraulic plants have started with, say, 80 per cent recovery of the potential energy, and efficiencies of even 90 per cent have been reached so that no material progress may be expected in increasing the efficiency of hydraulic plants.

As a corollary to these considerations, it follows that with the free play of economic laws in industry, everyone must recognize the latent weakness of extensive water power development, except under the most favorable conditions of cost of development, marketability of product and liberal terms of water grant.

The following tables give comparisons of the *relative values* of hydroelectric and steam power for a number of specific conditions of service which cover all possible ranges of conditions that may exist for different situations of power production from very large plants equipped with modern apparatus.

I again note that the costs given are only theoretical relative increment costs based on pre-war prices of plant installation and operating labor. Actual costs were higher before the war and would be considerably higher at present both for hydroelectric as for steam power, but relatively higher for hydroelectric on account of greater investment charges.

I. WATER POWER CONTINUOUS—33⅓ PER CENT

Average Yearly Use of Kw. Maximum demand = 2920 Hours—Auxiliary Steam Plant 50 Per Cent of Capacity of Hydro Plant.

	Cents per kw-hr. for coal at			
	$1 per ton	$2 per ton	$4 per ton	$6 per ton
Hydroelectric	0.564 cent	0.564 cent	0.564 cent	0.564 cent
Hydro with 50 per cent steam	0.701	0.711	0.731	0.751
All steam	0.393	0.460	0.593	0.727

II. WATER POWER CONTINUOUS—66⅔ PER CENT

Average Yearly Use of Kw. Maximum Demand—5840 Hours—Auxiliary Steam Plant 50 Per Cent of Capacity of Hydro Plant. Similar estimates Have Been Made, from Which We Abstract the Results Comparing the Yearly Unit Costs and Cents Per Kilowatt Hour for the Different Sources of Power.

	Cents per kw-hr. for coal at			
	$1 per ton	$2 per ton	$4 per ton	$6 per ton
Hydro-electric	0.297 cent	0.297 cent	0.297 cent	0.297 cent
Hydro with 50 per cent steam	0.367	0.372	0.382	0.392
All steam	0.250	0.316	0.450	0.584

III. WATER POWER CONTINUOUS—91 PER CENT

Average Yearly Use of Kw. Maximum Demand = 8000 Hours. In this Case, as the Power is Practically Used Continuously, We Assume that, when Transmitted to Long Distances, it Will Require a 100 Per Cent Reserve Steam Station—Instead of the 50 Per Cent Assumed in the Two Previous Cases.

	Cents per kw-hr. for coal at			
	$1 per ton	$2 per ton	$4 per ton	$6 per ton
Hydro-electric	0.218 cent	0.218 cent	0.218 cent	0.218 cent
Hydro with 100 per cent steam	0.298	0.302	0.322	0.329
All steam	0.199	0.265	0.398	0.530

In the case of water power with variable flow, a condition prevailing on almost all rivers except those fed from the Great Lakes, we find that it is necessary to install a 100 per cent steam plant auxiliary for carrying the deficiency of low water flow and as a reserve against interruptions of transmission lines if the water power is utilized at considerable distance from the power plant. The amount of energy output require from the auxiliary steam station depends upon the load factor of the system and the period of drought on the hydro plant. For average conditions we obtain the following comparative results for similar conditions of service as figured in the case of *a constant water flow*.

IV. WATER POWER VARIABLE FLOW—33⅓ PER CENT

Average Yearly Use of Kw. Maximum Demand = 2920 Hours (2190 W.P —730 Steam)—100 Per Cent Reserve Steam Station.

	Cents per kw-hr. for coal at			
	$1 per ton	$2 per ton	$4 per ton	$6 per ton
Hydro with 100 per cent steam	0.825 cent	0.841 cent	0.876 cent	0 910 cent
All steam	0.393	0.460	0.594	0.726

V.—WATER POWER VARIABLE FLOW—66⅔ PER CENT.

Average Yearly Use of Kw. Maximum Demand = 5840 Hours (4380 W. P.—1460 Steam)—100 Per Cent Reserve Steam Station.

	Cents per kw-hr. for coal at			
	$1 per ton	$2 per ton	$4 per ton	$6 per ton
Hydro with 100 per cent steam	0.448 cent	0.465 cent	0.499 cent	0.532 cent
All steam	0.250	0.317	0.450	0.585

VI—WATER POWER VARIABLE FLOW—91

Average Yearly Use of Kw. Maximum Demand = 8000 Hours (6000 W. P. —2000 Steam)—100 Per Cent Reserve Steam Station.

	Cents per kw-hr. for coal at			
	$1 per ton	$2 per ton	$4 per ton	$6 per ton
Hydro with 100 per cent steam	0.341 cent	0.356 cent	0.386 cent	0.416 cent
All steam	0.199	0.265	0.399	0.530

Under present prices these estimated costs would be larger. This would influence especially the overhead charges for plants, which would make the relative increases larger for hydroelectric than for steam power. It appears from these comparisons that hydroelectric power offers material advantages only when it is continuous and is so used, but that, on the other hand, the cost of steam power is less than that of hydroelectric power for ordinary conditions of service, load factors and price of coal. For such conditions it may also be noted that even relatively large differences in unit cost are of a trifling amount in comparison with the total cost of service including all other items, common both to steam as well as to hydroelectric power, covering costs of transmission, distribution, metering, billing, etc.

Recognizing these economic conditions, it becomes evident that in shaping the policies of utilization of potential water powers to the best end of preserving investment and conserving fuel resources, hydroelectric developments yielding relatively large amounts of continuous power should be co-ordinated primarily to supply energy for the production of products which require large amounts of continuous power such as can best be generated from water powers. Following this policy, it is conceivable to see large centers of electrochemical industries developed in a not distant future to produce nitrates for chemicals, munitions and agricultural fertilizers, caustic soda, electrolytic copper, electrolytic zinc, aluminum, calcium carbide, carborundum, graphite, etc. As for other applications, while today it may appear visionary to state that eventually no steel will be produced without passing through the electrical refining process, some steelmen are firmly convinced that electrical steel will ultimately become standard, because of the saving that all users of such steel will be able to make in reduction of material owing to its great elastic limit and its uniformity.

Some of these industries are in their infancy; others are now either consuming great quantities of coal or contending against great odds in their development because of shortage in cheap electric power within commercial distance of the raw products.

By concentrating waterpower developments into these intensified fields of electrochemical and refining products, there would result the attendant economies of mass production which are an absolute necessity to enable any American industry to flourish or meet foreign competition with its cheaper labor. If, for instance, the utilization of the major part of the Niagara Falls power could be arranged for between the United States and Canadian Governments, it would not be a great stretch of imagination to forsee that center become the Pittsburgh of electrochemistry and electro metallurgy with railroads and waterways reaching out to the most inland points and to the oceans.

Developments on rivers with irregular flow can in general only be used with full economy when employed as auxiliaries to or in connection with steam power systems of relatively much larger capacities.

In the mountain and Pacific States, where the potential water powers are enormous, the development of these resources, to save the wasteful use of fuel oil, should be fostered on the widest possible scale.

7. PERCY H. THOMAS

The Super-Power Plant

The following discussion is intended to cover the chief factors underlying the economy and operative feasibility of the proposed scheme for interconnecting the electric power systems of the district of the country lying along the north Atlantic seaboard and putting them in reach of the cheapest sources of steam and water power. With the interconnection is associated the electrification of the principal railways. The existing power companies in the district and the railroads now electrified or which it is proposed to electrify constitute the principal power consumers and distributors and must form the nucleus of the system.

The most fundamental object and the most important advantages of the project from the community's point of view, are the conservation of coal and the relief of the railroads from the burden of hauling coal for their own use and for power supply, which coal haulage constitutes more than one-third of the total traffic. Other advantages are mutual support and interchange of power among power companies, more favorable diversity factor and cheaper generation of power.

To conserve fuel most effectively requires both the development of as much water power as may be economically justified and the burning of coal in the most economical manner, as well as the use of low grades of coal. To relieve the railroads of the burden of freight, requires the burning of coal as near the mines as feasible. Furthermore, economical generation of steam power requires use of large power houses. To meet all these conditions requires long transmission and a very great premium is thus put on low priced and economical transmission lines. In fact, operative practicability and low cost of transmission are the essential features of this project. This means the simplest practicable layout and the greatest possible power capacity.

The system shown in outline in Fig. 1 is suggested as one solution of this problem and as a suitable basis for discussion.

This system consists of a main 250,000-volt line connection Washington or Baltimore with Boston, via Wilmington, Philadelphia, Newark, New York, New Haven and Providence. This line is fed from a group of large stations at the nearest soft coal fields—perhaps on the upper branches of the Susquehanna, but in any case where condensing water can be obtained and from a second group at the hard coal fields, probably supplemented by the Susquehanna and Delaware River water powers. Each group of such powers would feed through a tap transmission line. If a large plant or plants on the St. Lawrence River should turn out to be feasible, another tap line could be run to connect with the main line probably where this line crosses the Hudson River. The length of this line would be about 250 miles, this distance being taken to a junction point with the main line. The total distance to New York probably will be 300 miles or somewhat over.

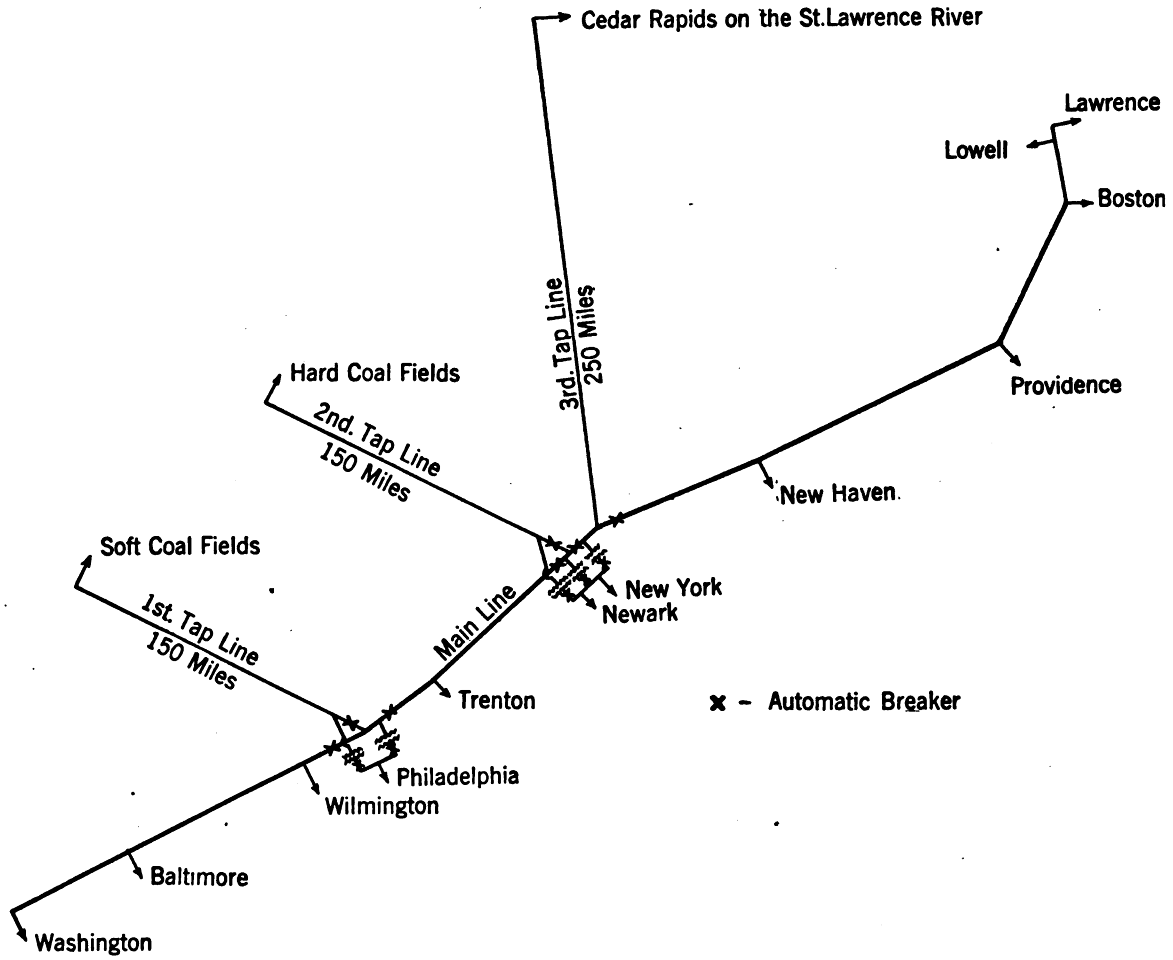

Fig. 1

I would like to call attention to the fact that I have not fixed upon any definite locations for actual coal mine power houses, but have made assumptions as to the probable minimum distances involved. The actual selection of a site or group of sites might add materially to these distances. The only effect, however, of an increase of 25 per cent to 35 per cent in the transmission distance would be to increase the line losses approximately proportionally to the distance and the cost in proportion to the added length. It would have very little effect in the final conclusions. Since the exact location of a site must be determined by suitable cooling water it will obviously be necessary to make use of a certain amount of railroad haulage of coal. This would be necessary in any case since coal must be collected from a number of mines. This is not objectionable if the coal does not have to be hauled long distances nor over main trunk lines. The west branch of the Susquehanna around Williamsport and Lockhaven is one possible site for a large plant. This plant would be fed from the Clearfield coal district. As an alternative, a power station might be located on the Potomac River somewhat below the Maryland coal fields and the transmission from there to Baltimore would be less than 150 miles. The latter alternative would probably work out to about the equivalent of the other as to cost and as to operating quality.

These two or three generating groups would supply the base load or the maximum continuous 24-hour power for all the territory fed by the main line—amounting to perhaps one-third of the peak load. To carry out this idea with the assumed conditions, the single circuit tap lines should have the maximum possible capacity, which is here taken as 350,000 to 400,000 kw. per circuit. To secure such a capacity at 250,000 volts, requires a number of innovations, which will be discussed later.

It will not be desirable for consumers except the very largest to be connected directly to the 250,000 volt lines on account of complications and the expense. Local consumers in any district can be supplied from the nearest large distributing company. Small water powers or groups of neighboring powers up to 25,000 to 50,000 kw. would be connected with the nearest distributing system without connection to the 250,000-volt system.

As the load in the district grows, additional 250,000-volt circuits can be added from suitable generating sites—probably all more or less widely separated—preferably single circuit lines.

It will be desirable to make use of and depend upon the present large generating stations to supply all peak and breakdown service. Voltage would be independently controlled at the principal points of the system, as for example, Philadelphia, Baltimore, New York, Boston, as will be later explained.

For example, Philadelphia would receive the first tap line and control its voltage and feed the surplus up and down the main line. Similarly with Newark and New York for the second tap line, and also for the third line to the St. Lawrence if this should be later added.

General Features. The new generating plants should be designed for maximum simplicity and low cost. They should be based upon full load operation at 90 to 100 per cent load factor. Turbines and generators should be designed for best efficiency at this load. Boilers should be built for high rating and long continuous runs—with distilled water makeup. Very likely coal should be burned in powdered form and the largest units should be used.

The highest steam pressure, probably 500 lb., with at least 200 deg. superheat and economizers with air heaters for preheating air for combustion from exhaust gases and the heat in the generator cooling air should be used. A house turbine operating condensing with the condensate of the main units for cooling water would be used having as large a capacity as can be handled with the amount condensate available. In addition, atmospheric exhaust auxiliaries would be used to the maximum extent permissible without too high a feed water temperature.

Generators would be synchronous type with governors for controlling the field current, the governors being set for a definite load and the fields controlled automatically to keep a definite power factor—about 98 per cent to 99 per cent lagging and also to take a certain definite amount of charging current at no-load. The reason for this will be explained later.

There would be great advantage in the use of non-synchronous or induction type generators, but their bad power factor and high cost are too much of a handicap to be overcome, unless the characteristics of such generators can be made much more favorable in large sizes than in present sizes; which unfortunately does not seem to be the case.

Large power houses must be located near large and reliable supplies of cooling water—400,000 kw. would require approximately 1500 second-feet flow—or a large lake whose waters could be used over and over, cooling meanwhile.

If a large enough power plant could not be gotten at one point, several closely adjacent plants might be used, all feeding at perhaps 15,000 volts to some central point for stepping up.

High tension transformers would be connected directly to the line—with opportunity of uncoupling the line dead—but no standard disconnect switches. Something in the nature of a very long enclosed fuse might be introduced for short circuit protection

Synchronizing could be done on either end, but on the low tension side, preferably in the new power houses, however.

No means for automatic circuit opening would be provided, except at the six points (7 points if the third tap line be supplied) shown in Fig. 1. At points where one line connects with another, appropriate towers should be placed close together and facilities provided so that the lines could be cut apart in case of emergency.

The transmission lines proposed have a capacity power something like three or four times as large for a given voltage as heretofore proposed. They have the further advantageous property that they transmit normal power with a very small loss of energy or voltage and at the same time will permit only a relatively small current to flow in short circuit. This is a rather remarkable and very useful property. For example, either 150 mile tap line will permit only about three or four times full load with one end short-circuited.

This favorable design of line is obtained only by careful proportioning and if the load on the line be properly chosen. The load is so taken that the charging current of the line neutralizes the lagging effect of the load current in the reactance of the line.* The proper load for this balance can be made to approximate the desired load of 300,000 to 400,000 kw. by using such construction as to give an abnormally large line capacity and a correspondingly small line reactance. The use of aluminum and the dividing of the line conductor into several separated cables or parts

*See *Output and Regulation in Long Distance Lines*, by Percy H. Thomas. TRANSACTIONS A. I. E. E., 1909.

as described hereinafter, sometimes called the "Split Conductor," have a very marked effect to increase capacity and reduce inductance.* This construction also helps greatly in reducing corona and skin effect. Obviously if load and line constants are so chosen that the inductive effect of the line current is balanced by the capacity current at normal voltage, this balance will be lost when a short circuit occurs and the charging current largely disappears. As the charging kv-a. go down as the square of the voltage, and the inductive effect goes up as the square of the current, the capacity effect will be negligible on short circuit conditions, leaving the reactance drop the controlling factor. This explains the favorable behavior of this line to limit short circuits above stated.

The layout of Fig. 1 is favorable, since the general effect of the long interconnecting or main line is to increase the system power factor. Power in large quantities is not regularly transmitted in any one direction over the whole length of the main line but blocks of power will pass in alternate directions in adjacent parts and the drop voltage along this line is practicably negligible. For this reason the capacity will not be neutralized in the main line by the effect of the load current in the line inductance but will be available for power factor correction.

It has just been stated that the drop between any two neighboring large stations on the main line will be very small. This is not only desirable but necessary for when power is to be quickly supplied in reverse direction from normal flow, as for example, on a sudden call for help, this reversal of power could hardly be accomplished practically, if there were a large line drop, since the voltage delivered to the station ordinarily sending out power would be too low to be useful when the direction of power was reversed.

But with a line of very low ohmic drop, like the lines here proposed, transfer of energy backward or forward on the same line may be easily accomplished, for by manipulating the field strengths of the generators on both ends of the line, out of phase or circulating current between the generators can be made to counteract the ohmic drop of the load current. This increases line losses somewhat but line loss would be unimportant at time of emergency and would be small in amount in any case. As a net result of these considerations power can be sent in either direction between two points without changing the voltage at either end, the necessary flow of power being caused by suitable change in the power factor of the passing current.

Operation

As already stated, under normal conditions the new power houses would send current into the main lines in a constant rate 24 hours a day and no changes would be made for load or seasonal conditions. In case of accidents to line,—which should be very rare,—it is proposed that a certain amount of automatic protection would be provided. The transformers at the station which receives power from one tap line are divided into two parts, one connected to the tap line, the other to the adjacent main line. In case of trouble on the tap line, the tap line circuit breaker would open leaving the connection between sections only through the banks of transformers, stepping down through one and up through the other, and then the main line transformers or the tap transformers would be automatically cut off on the low tension side as might be called for, leaving the good line operating. The bad section of the system having been cut out, the good parts of the plant could be operated without the bad part. This would be accomplished by relays.

In testing the insulators and making changes of insulators, it is assumed that this work will be done alive by the method used by Johnson in Georgia. While this sounds chimerical to a person not familiar with what has already been accomplished, I believe it to be entirely possible and safe.

Starting Up. Starting could be readily accomplished on account of the subdivision of the high-voltage lines. Philadelphia will excite the section of the line to Newark by the low-tension switches through one set of transformers. This is too short in length for the charging current to be important and will furthermore merely relieve the lagging power factor of the Philadelphia system without increasing load or current. New York can then synchronize with Philadelphia on the low side. Philadelphia will then excite first tap line on its second bank of transformers. This will call for no increase of current at Philadelphia as before on account of the great excess of load lagging current. By connecting the power house transformers at the coal mines before exciting the line, no synchronizing on high voltage would be necessary. Newark or New York would similarly excite the second hard coal tap line (and the third if installed). The line in Baltimore may then be energized at Philadelphia and Baltimore synchronized on the low-tension side. Similarly with the line to Boston, and the system is operating ready for load. The two tap lines which so far are connected only by step up transformers would be connected to the main line at leisure by the high-tension circuit breakers, the system being already synchronized.

The switches or breakers shown in Fig. 1 can be used for automatic cutting apart of the sections of the high-tension system as already explained. On account of the characteristics of the transmission lines as here laid out, these coal mine stations will add little to the short circuit currents; and one center like New York will supply little short circuit current to another as Philadelphia.

Spare Lines. This scheme of Fig. 1 offers no spare lines. It is not believed that the expense of a spare line is warranted. It will be noticed that no accident

*TRANSACTIONS A. I. E. E., 1909, loc. cit.

at any one point of the line can cut out more than a small part of the system except momentarily—nor more than one of the mine power plants. If the system grew it would be possible to add other tap lines at suitable points, which would reduce the power shortage due to any failure without providing any idle lines. It would probably be more economical for the community as a whole to make the best shift possible to a certain extent in case of a serious line failure than to pay the charges and endure the disadvantage of the complication of spare lines and additional switching facilities.

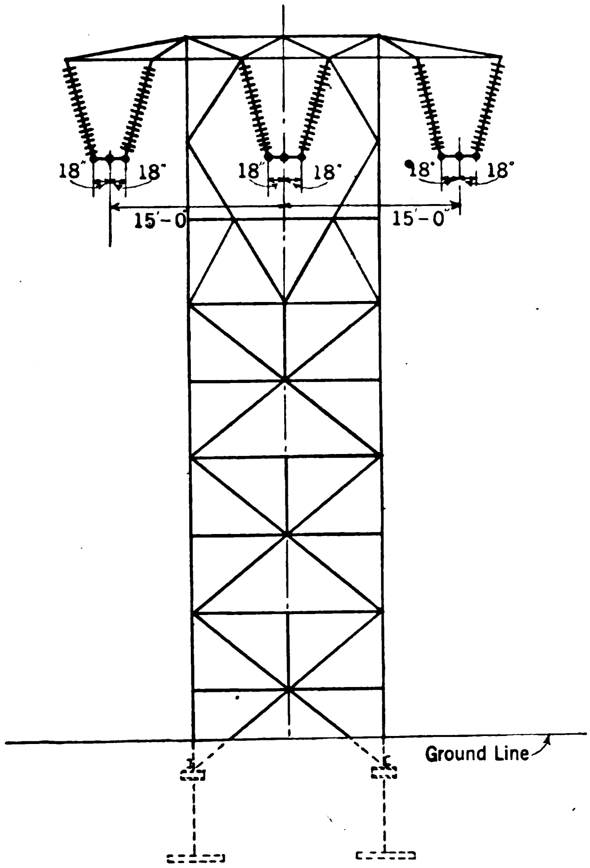

FIG. 2

Transmission Line. The conductor has been chosen as consisting of three 600,000-cir. mil. aluminum with steel cores. These would be placed in a horizontal plane, 18 to 24 in. apart each hanging from two strings of insulators suspended at an angle, as shown in Fig. 2. This would reduce side swinging and help clearances. Furthermore, if one insulator string should be broken the other would hold up the conductors.

The principal strain on the towers, according to the usual test specification, is due to a broken conductor causing torsion. To reduce this requirement and so lighten the towers as far as possible—suspension towers should be arranged with the conductors free to slide in the hanger, or held only by a moderate grip, having a maximum positive hold. The conductor will tend normally to equalize longitudinal stresses in the adjacent spans automatically and not to develop unevenness. The one danger is the uneven collecting or falling of ice and sleet. A moderate grip on the hangers such as would be justified by the strength necessary in the tower for other requirements would be sufficient to prevent any permanent slipping except in case of a conductor broken in all three cables. In this case the conductor will slip in one or more hangers and drop on the ground. The drag on the ground will prevent the line slipping in many towers. Repair in any case will be a big undertaking. The breaking of a single cable of the three of any phase would cause an electrical ground but no slippage.

The assumptions here made are confessedly a departure from standard practises of the present and mature discussion may or may not prove them warranted. The results accomplished will be somewhat less installation cost, with, I believe, no material increase in the danger of line interruption, this being account of the special hanger or cable clamp assumed.

For most economical construction all ground wires should be omitted. Whether the installation of ground wires would eliminate enough trouble to warrant the expense and complication introduced is a debatable point. It is probable that indirect or induced surges will not be sufficiently severe to affect the lines, since the lightning effects do not depend primarily on the line voltage and since disturbances of this nature on our highest voltage lines seem comparatively rare. Direct strokes of magnitude will not be turned aside by ground wires and the most that can be expected of ground wires would be the elimination of certain disturbances of intermediate severity.

The 150-mile tap lines as shown when delivering 300,000 kw. at 250,000 volts and 99 per cent power factor lagging will have an energy loss of 3½ per cent and a drop of about 5 per cent and the generator power factor unity. It is essential that calculation of this line be made by an accurate formula, such as the hyperbolic function method, taking account of distributed inductance and capacity. Formulas based on localized capacity will give misleading results. The critical condition to cause this failure of the approximate formulas is the one here existing, *viz.*, that the leading and lagging effects of capacity and inductance balance, leaving substantially ohmic losses. With the reactance seven times the resistance the importance of this consideration is evident.

With 400,000 kw. delivered, the energy loss would be 5 or 6 per cent and the line drop about 9 per cent. With 300,000 kw. and a lower power factor the efficiency would go down and the line drop up, but a considerably lower power factor would not give unduly unfavorable conditions. It is here assumed that the existing generating apparatus when coupled up with these lines will be able to supply the necessary out-of-phase current to permit a high power factor in the delivered line load. If not, synchronous condensers can be used as is now customary. With a lightly loaded

line the automatic power factor control on the coal mine generators already described will secure a condition such that there will be almost no voltage change between light load and full load at the power house. Since voltage is established at the receiving end there will be no voltage variation there.

The essence of this arrangement is that the coal mine generators shall be set to take automatically a definite power factor at and near full load and yet will take automatically a certain amount of charging current at or near no load. These adjustments should be so made that with full load a slightly lagging power factor shall be maintained automatically at the receiving end of the tap lines. With the voltage regulating apparatus of the distributing system at the receiving end in entire control of the delivered voltage the system will maintain itself in proper adjustment to give the efficient line conditions required—that is approximately unity power factor in the line.

Costs. It having been established in the general terms that the operating characteristics of the super system as proposed are satisfactory and in many ways unexpectedly favorable, the questions of capital and operating costs remain.*

Capital Cost. It may be assumed that a 400,000-kw. power station may be built, under reasonably favorable price conditions for $100 a kw. including overhead necessary for design and construction; that the transmission lines as proposed, *viz.*, two 150-mile 250,000-volt, 400,000 kw. tap lines and 100 miles of similar capacity line for the central part of the main connecting line, and 250 miles of 200,000-kw. line, can be built at an average cost of $47½ a kw. generated, including overhead. Also that the necessary 250,000-volt step up and step down transformers with 250,000-volt switches could be installed for $15.00 a kw., giving the following table:

	Per kw.	
2-400,000 kw. power houses	$100.00	
700 miles 250,000-volt transmission lines	47.50	
250,000-volt transformers and switches	15.00	
Miscellaneous	1.50	$164.00
Total for 900,000 kw., allowing 12½ per cent spare		$150,000,000.00

Taking into account the added cost of real estate, the congestion of fuel handling in the large cities and the complication of handling large blocks of power underground from city stations, a fair estimate of the cost of installing plants to generate this same amount of power at the several large centers, supposed to be supplied, would be about $125.00 per kw., leaving an excess capital cost on account of the transmission scheme of $40.00 per kw., a very small amount for the benefits offered. The value of the 800,000 kw. delivered to the large distributing companies should be in the neighborhood of $20,000,000 to $25,000,000 a year, with present or slightly better conditions.

These cost figures are fairly liberally estimated on the basis of routine construction, probably 10 to 20 per cent should be added to cover additional cost due to the unusual character of much of the work.

Comparing the cost of transmitting the power over transmission lines with the cost of hauling coal by rail, we have to compare the freight on five tons of coal (a sufficient quantity to produce a kilowatt for a year) against the cost of 10 per cent additional coal (required to cover losses in transformers and transmission) plus $3.50 fixed charges on excess capital cost of one kilowatt for the transmission system. That is with coal at $1.00 per ton at the soft coal power station, five and one-half dollars worth would be required for each kilowatt-year. Adding $3.50 excess or fixed charge, gives $9.00. For coal hauling to be on an even basis, coal freight would be 80 cents a short ton. Most of this is on account of interest on the excess investment. This, however, charges the transmission system with 700 miles of line while the actual distance of transmission is only 2 × 150 miles. If the cost of 150 miles, the direct transmission only, is considered, the capital cost may be taken as 12½ per cent less, giving a fixed charge of $2.00 a kw. and a corresponding freight rate of 50 cents a ton. All the above figures are in short tons.

I wish to say that all the above dimensions and estimates are based on the assumption, that the inter connecting system will be characterized by extreme simplicity and that very little so-called flexibility will be provided. This is necessary to reduce costs and to simplify operation and is justified by the completely equipped plants already operating in the interconnected district.

These approximate figures give an idea of the actual and relative cost and of some of the results that might be obtained by interconnecting the district and supplying from the coal fields the base load for two or three million kilowatt of maximum load now existing. With the future growth of the load and the electrification of the railroads, the St. Lawrence development, or additional coal mine plants, might well add another half million kilowatts in one or two circuits, on a basis more or less on a par with the above, except that if the new power should be hydraulic, it would probably call for a somewhat larger capital expenditure and would show a lower operating cost.

Attention is again called to the fact that the present discussion is based on a hypothetical typical case and not on an actual group of definitely located power houses. Variations of 25 to 50 miles in the length of transmission will, however, make little difference in the net result.

*In this present discussion very free use has been made of the excellent paper, *Problems of 220 Kv. Power Transmission* by A. E. Silver, A. I. E. E., 1919.

It is to be hoped that as the cost of generating electric power is reduced, partly by the development of such large scale systems as here discussed, partly by the natural development of the art, and partly also by the freer use of local distribution mains, that the use of electric power for heating and cooking and small power will be enormously increased, which will warrant the building of the largest systems, becoming a great source of comfort to the community.

So far no account has been taken of the benefit from the inter-connecting system here under discussion in its opportunity to take advantage of diversity factor in general power consumption nor of its very great advantage in raising the load factor of a railway load, which is at best very low. The relay and breakdown service of the interconnecting line would be of great benefit. Another advantage accruing is the ability of the system to apply a surplus of power existing in any one system, either temporary or permanent, to any load that may be available. This ability is of much importance in a growing district. Furthermore, the ability to locate very large consumers of power at the most favorable location would be of importance. For example, a large electric furnace plant can now only be placed near some large system, without installing a special power plant. Other similar advantages of the interconnected system exist, but enough has been said to warrant a careful study of its advantages, disadvantages, possibilities and limitations.

8. W. D. PEASLEE

High-Tension Insulators

The utilization of 220,000 volts or higher for the transmission of power is not a problem that holds any terrors for us as insulator manufacturers.

Due to the size of the cable necessary on such a line and to the fact that it seems rational to design the line for more severe storm loading conditions than standard for an ordinary line, the standard disks suspension insulator as at present manufactured is not entirely satisfactory from a standpoint of mechanical strength.

An insulator for 220,000 volts will have to stand very severe operating conditions as to mechanical stresses and dielectric flux concentrations, and it is very important that certain features of insulator design be followed carefully in any insulator presented for this service. Due to the large size conductors necessary and the spans, the mechanical stress will be considerably in excess of that met with in high-voltage lines now in operation.

The ratio of puncture to flashover in any unit is a very important feature of its design and one which unfortunately has been neglected in most conventional designs of insulators. Due to the effect of transients added to the normal frequency voltage of the line and their time lag or impulse ratio, it is possible to stress the end unit of a string to very high values, and for that reason its actual puncture resisting power should be very high. The puncturing voltage of a disk insulator for such service should never be less than 2½ times the dry flashover voltage of the unit.

In order to reduce corona formation as much as possible, the unit should be designed to reduce the flux concentration and in such a way that the corona forming voltage will be considerably above the operating voltage impressed upon the unit.

For an insulator for service of this kind strength is an important factor. The lines are very important and the ability of the insulator to withstand power arc shock and other events, is of the greatest importance to the continuity of service of the line. We have made a very careful study of the requirements of this insulator.

We are at work at the present time on a disk insulator to meet this requirement. It will be a disk insulator probably of larger diameter than the present design, with a mechanical strength sufficient to meet the strains imposed by the larger loadings necessary in such a line; dry flashover in the neighborhood of 125,000 volts. It will be designed in accordance with the correct theory of surface design between the air and porcelain, and with this design the corona-forming voltage will be very high. The approximate puncture voltage per disk will be in the neighborhood of 300,000 volts, thus securing the high ratio of puncture to dry flashover now recognized as a vital point in correct insulator design.

From these characteristics you will see that this disk will be very well suited for this particular work and our research work has progressed far enoush so that we feel confident that by the time such a line is an active proposition, we will be able to undertake the insulation problem. Not more than eight to ten units will be required for the 220,000-volt grounded Y line and this will give a string of insulators from 65 to 80 in. in length.

9. A. O. AUSTIN

High-Tension Transmission Systems

It would seem that the super-power project such as Mr. W. S. Murray has outlined, must become more and more of a necessity with each succeeding year. The project would necessarily change in character in time, but the sooner it is started, the greater the saving that would be effected, both as to the economy of operation and the saving of natural resources. The very magnitude of a system of this kind tends to postpone a start on the project, even though the possible economies increase with the size and completeness of the system.

The project must necessarily depend upon an efficient transmission system, and as the cost of the connecting transmission line will be an important factor, it is necessary that we consider the state of the art with a view of adopting a transmission system which will show a maximum economy. Anything effecting the cost of the transmission system should be given careful

consideration, for the greater the economy shown the more quickly will a system of this kind be put in operation. Where a project of this magnitude is involved it would seem that a departure from the usual practise is well warranted, particularly where an increase in reliability and a decrease in cost can be effected.

It is possible that at the start, a large part of the system could be connected to advantage with a transmission line not exceeding 110 kw. It is probable, however, that power will be transmitted from large hydroelectric or steam plants located at a considerable distance. The increasing cost of coal will make it highly advisable that the future additional generating equipment be located where the greatest economy can be effected, rather than split up into a lot of smaller, less efficient stations.

The adoption of a high line voltage for the main trunk system would show a saving which might hasten the project several years, consequently it is important that we consider various factors which may be taken advantage of, to increase the efficiency or lower the cost of the line.

The real problem on a large transmission system operating at a high voltage, has usually been that of regulation, and it would seem that the present project is no exception to the general rule. It would seem that the future demands for power in the zone covered by the project would permit the installation of equipment without additional cost, which would give the necessary regulation to insure the success of the system All that would be necessary would be to form a comprehensive plan and install future equipment so as to make the scheme effective.

A transmission line operating at 220 kv. or slightly above will involve large conductors, which would give the system a high degree of mechanical reliability not afforded in the smaller systems. In addition the insulation which would be necessary for the line and equipment, would make the system free from lightning trouble. These two factors would be important in eliminating the necessity for stand-by plants, and should hasten the adoption of the project. The large amount of power would permit of apparatus of a high degree of strength and reliability, so that shut-downs from failure of same would be negligible.

A careful analysis of operating systems would probably indicate that the greatest danger to a system of this kind would be that due to suddenly dropping a large portion of the connected load. This hazard could probably be entirely eliminated by tieing in the main transformers connected to the system, so that they could not be disconnected by the operator unless the voltage of the system was lowered or a defective unit alone be disconnected. Since apparatus would probably be disconnected only in case of failure, a shunted fuse or other inexpensive device could be used to disconnect the defective unit. This would eliminate a considerable cost for oil switches and the freedom from lightning would probably permit the elimination of lightning arresters. This would effect a considerable saving and might advance the installation of the completed project several years.

It is highly desirable to make the main system simple to give the highest degree of reliability and it would seem that in carrying this out that economies could be effected which would more than off-set the increased cost for the higher voltage transformers necessary to permit an economic transmission system for supplying power for a considerable distance. The large conductors necessary for a system such as this would require heavy working stresses for the insulators. The insulator art, however, is such that high ultimate insulators with longer life can be produced at a much lower price than they could previously. It is now possible to procure insulators such that a single string will carry the line and at a cost probably not more than 50 to 60 per cent of that required for a 110-kv. line. From this it will be seen that the cost of installation for a 220-kv. project would probably be less than the cost of some of the 150-kv. lines previously installed. The transmission art has advanced rapidly and many economies could be effected by carrying out a comprehensive scheme, which are not possible in many of the existing systems.

Large additional amounts of power will be required in the district effected by the project and much could be saved by adopting a plan as soon as possible. It would seem that there is no new or untried principle involved, and that by making a survey it would be possible to show the economies which would be effected not only for the present, but for some years to come. It takes considerable time to put large projects into operation, hence it is important that we do not confine our attention entirely to the immediate economies, but look more to the future.

The Baldwin-Westinghouse Chicago, Milwaukee & St. Paul Electric Locomotives

BY N. W. STORER

General Engineer, Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

Requirements

In the summer of 1917, the Chicago, Milwaukee & St. Paul Railway Company issued specifications covering the apparatus necessary for the electrification of their line from Othello to Seattle and Tacoma. The following were the principal requirements for passenger locomotives as finally determined by the Railway Company:

Power Supply. To be 3000 volts direct-current.

Route. Either the line between Harlowton and Avery, or the newly electrified line from Othello to Tacoma and Seattle.

Grades. The limiting grades are 2 per cent compensated for a distance of 20 miles from Piedmont to Donald on the east slope of the Rocky Mountains, and 2.2 per cent compensated for 17.8 miles from Beverly Junction to Boylston on the western division.

Alignment. The sharpest curve on the main line is 10 deg., but the locomotive must negotiate a 16 deg. curve in the yards satisfactorily.

Load. Twelve steel coaches weighing 950 tons.

Speed. The locomotive to be designed for a speed of approximately 25 mi. per hr. up a 2 per cent grade, about 35 mi. per hr. on 1 per cent grade, and to have a maximum speed of 65 mi. per hr.

Mechanical Design. The locomotive to have a four-wheel guiding truck at each end, of the "Woodard" type.

The driving wheels to be not less than 60 in. in diameter.

Regeneration. Trains to be held on down grades by regenerative braking.

Train Lighting. Current to be supplied from the locomotive for lighting the train and charging the train storage batteries at a voltage of 60 to 85.

Train Heating. The locomotive to be equipped with an oil-fired boiler, to be supplied by the Railway Company, to furnish steam for heating the train.

Storage capacity to be provided for 30,000 lb. of water and 750 gallons of fuel oil.

Thermostats. Thermostats to be provided that will automatically start the blowers for cooling the main motors when the motor temperature reaches a pre-

Fig. 1—Baldwin-Westinghouse 3000-Volt D-C. 275-Ton Passenger Locomotive for Chicago, Milwaukee & St. Paul Railway Co.

determined value, in order to limit their operation to that time when they are actually needed.

Description

A portion of the order for locomotives was secured by the Westinghouse Electric & Manufacturing

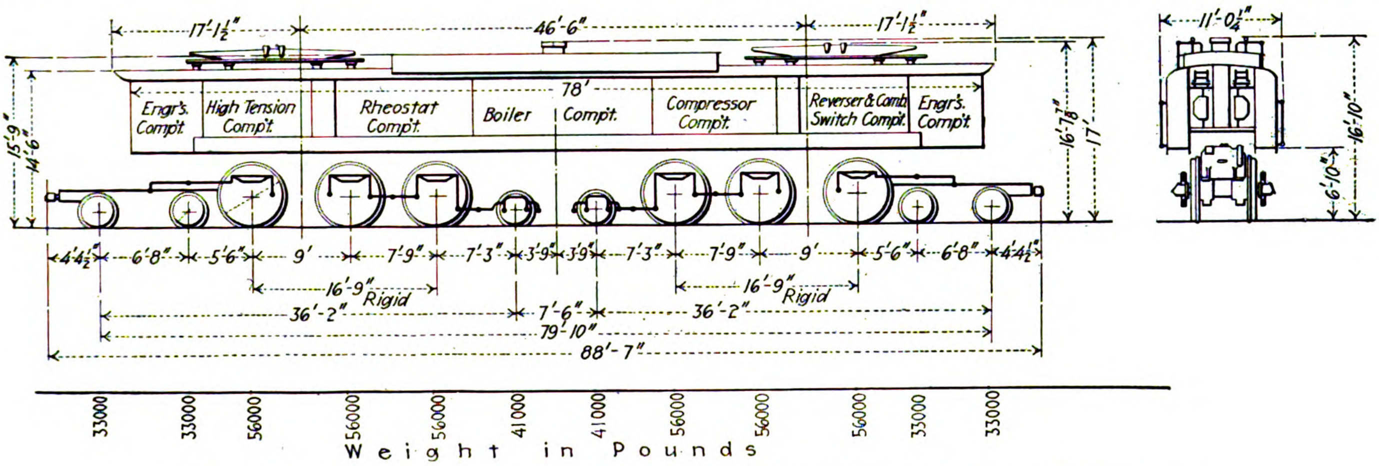

Fig. 2—Outline Showing Equalization Scheme, Weight Distribution and Wheel Base

Company, and this paper covers the brief description of the Baldwin-Westinghouse locomotive as furnished.

General. A view of the complete locomotive is shown in Fig. 1, and a diagram showing the wheel arrangement, axle loading and equalization, in Fig. 2.

The locomotive is built in a single unit, having

Presented at the Pittsburgh meeting of the A. I. E. E., March 12, 1920.

one long cab, carried on running gear of the 4-6-2 – 2-6-4 type.

The locomotive weighs 275 tons.

Main Running Gear. The running gear consists essentially of two Pacific type running gears, coupled back to back. One-half of the running gear is shown in Fig. 3. This shows the running gear complete with the motors mounted and the air conduit carried on top of the motors.

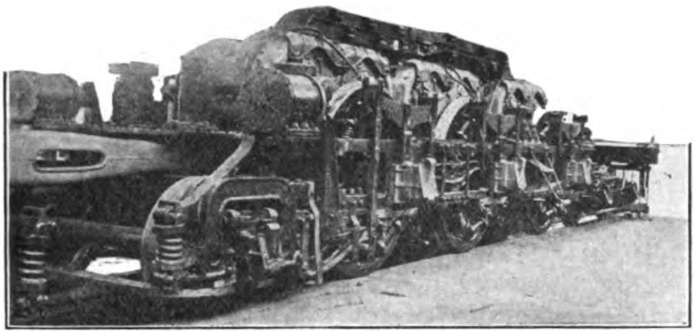

Fig. 3—One-Half Locomotive Running Gear, Showing Driving Motors, Coupling Bar and Air Conduit

The side frames are steel castings, joined over the four-wheel trucks by a heavy "A" frame casting; also by heavy cross-ties between the drivers which also support the motors, carry the center pin and carry the coupling between the two running gears.

Each half running gear has six spring-supported plungers on which the cab rests. There are two supports at each end and two in line with the center pin. By the use of shims, the distribution of weight between the two ends of each running gear may be adjusted as desired.

The equalization, as shown in Fig. 2, is of the standard three-point type; the leading bogie being cross equalized with the leading pair of drivers and the pony axle being equalized with the two adjacent driving axles on the sides.

Extra points are provided in the equalizing levers so that practically any distribution of weight that is desired can be attained.

The driving wheels are 68 in. in diameter; the journals 8½ in. by 14½ in., located outside of the wheels.

The drawbars, with Minor fraction draft gears, are carried in the "A" frame casting, previously mentioned.

The coupling between halves of the running gear consists of a long bar of a box section. This is shown in Fig. 3. The coupling pins are 10 in. in diameter and are located well inside the pony axles. The pins are hollow, filled with oil-soaked waste and have oil holes provided that keep the pins well lubricated.

Bogie Trucks. The four-wheel trucks are of the "Woodard" type with outside journals; 36-in. rolled steel wheels and cast steel side frames. The journals are 6½ in. by 14 in.

Pony Trucks. The two-wheel truck is of the well known "Rushton" side-bearing type, also with outside journals and 36-in. wheels. The journals are 6½ in. by 14 in.

Brakes. Brake shoes are provided on all drivers. A modified form of the 14-EL Westinghouse Air-Brake Company equipment is used.

Cab. The cab is 78 ft. 0 in. long, 10 ft. 2 in. wide; is strong and rigid so that it can be lifted at the ends. The main strength lies in the two bridge girders extending from end to end. The heavy cross-braces and the side members and top of the raised deck down the middle of the cab, form a construction that is light, but stiff. The cab is divided by cross partitions into compartments, one at each end for the engineer, and the others for the various parts of the cab equipment.

Locomotive Capacity. The total motor rating of the locomotive is 4200 h. p. on the one-hour basis. The continuous rating is 3400 h. p. The tractive effort and the speed are given on the nameplate of the locomotive as follows:

Rating	Tractive effort		Speed	
	Full field	Short field	Full field	Short field
1-hour rating	66,000	57,000	23.8	27.2
Continuous rating	49,000	40,800	26.0	30.4
Weight on drivers	168 tons			

Electrical Equipment

Driving Motors. The six driving motors are of the twin armature type. See Fig. 4. Both armatures are contained in a single frame, arranged to secure the maximum economy of weight. The fields are of the standard four-pole type with four salient poles and four inter-poles for each armature. There are brush-arms on each commutator which are easily accessible.

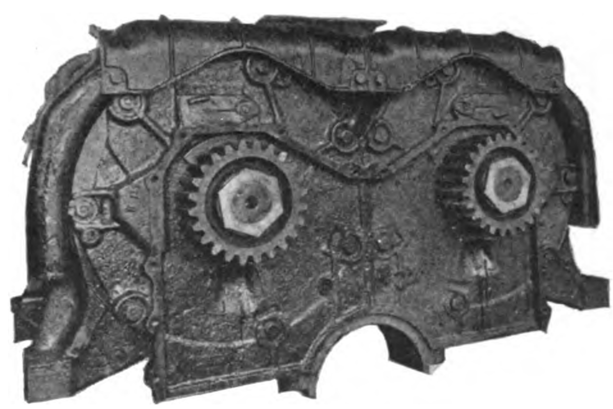

Fig. 4—700-H. P. 1500/3000-Volt D-C. Twin Armature Motor

Each armature is wound for 750 volts, but the two armatures and the two sets of field windings are connected permanently in series so that the rating of the complete motor is based on 1500 volts.

The motor is designed for field control by means of inductive shunts.

The one hour rating is 700 h. p. The continuous rating is 567 h. p. with forced ventilation and 400 h. p. without blowers.

The characteristic curves, when running as a series motor, are shown in Fig. 5. Curve sheet Fig. 6 shows the performance when regenerating.

Quill Drive. The motors are mounted rigidly on the cross ties of the running gear, one directly above each driving axle. Each motor is geared to a quill centered in bearings in the motor frame and surrounding the driving axle with a clearance all around when axle and quill are concentric of 1¾ in. The quill is connected to the drive wheels by long helical springs which are clamped rigidly at the ends in castings which are

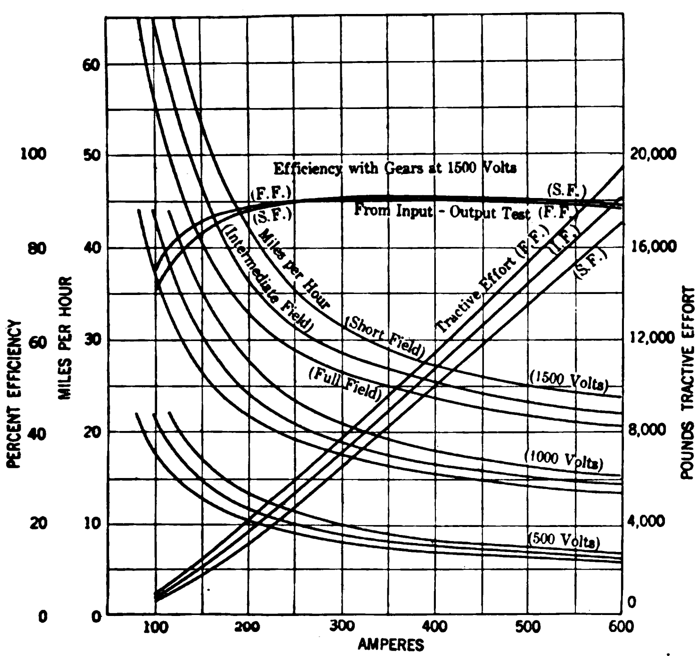

Fig. 5—Motoring Performance Curve of Driving Motor at 1500, 1000 and 500 Volts

bolted one to the quill flange and the other to the drive wheel. There are seven springs at each end, worked in compression in one wheel, while those in the other are in tension. All springs with clamps are interchangeable. They are easily accessible for inspection, and any spring may be removed without disturbing any other part of the running gear.

This drive is similar to the well-known quill drive of the geared locomotives of the New York, New Haven & Hartford Railway.

Main Motor Control. A schematic diagram of the main motor circuits with starting resistances and all stabilizing resistance and exciters for regenerative braking is shown in Fig. 7. The six motors are arranged to be connected in three combinations:

1. All in series, giving one-third speed.
2. Three in series, two in parallel, giving two-thirds speed.
3. Two in series, three in parallel, giving full speed.

Inductive shunts are applied to the fields on all three of these positions.

Shunt transition is used in passing from one combination to the next.

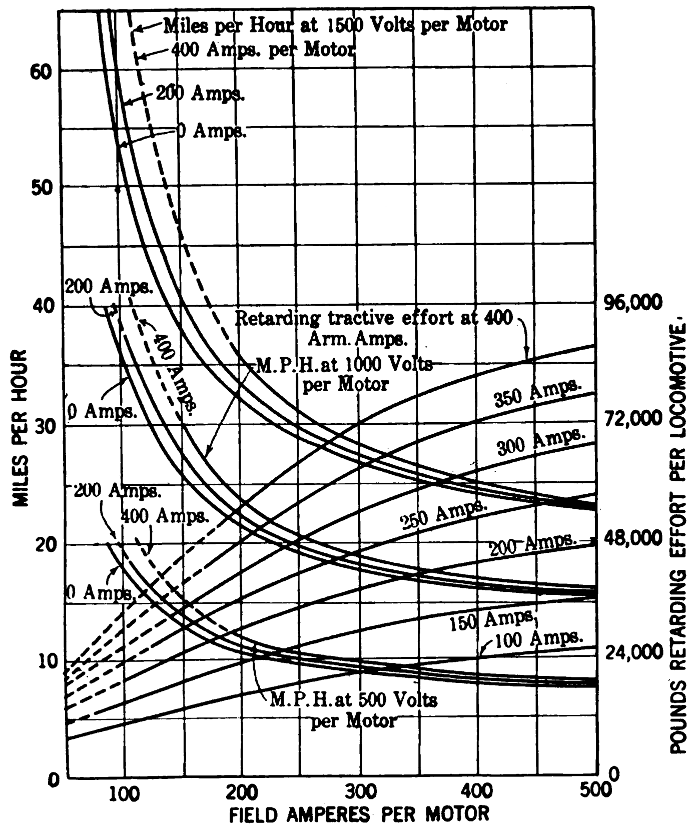

Fig. 6—Regenerating Performance Curves of Locomotive with 3000 Volts on Line. Speeds with First, Second and Third Motor Combinations. Current Shown is Current per Motor

Regenerative Braking. When regenerating, the motors are separately excited from two axle-driven generators which are carried on the inside axles of the two four-wheel trucks and geared to them like ordinary interurban railway motors. These generators are

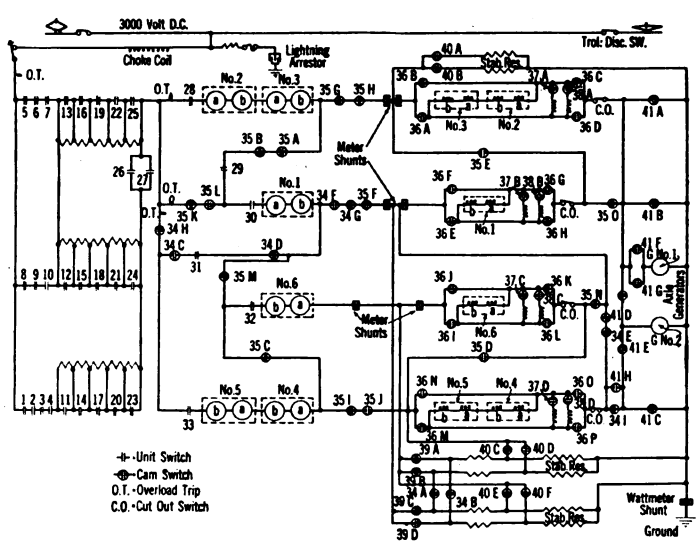

Fig. 7—Schematic Diagram of Main Motor Circuits

separately excited and the field strength of the main motors is controlled by varying the fields of the exciters.

The scheme that is used for regeneration includes the use of stabilizing resistance, which is connected in series with the exciter armature, main motor field circuit, and also with the main motor armature circuit, so that the field excitation is dependent, to a certain extent, on the armature current. A schematic diagram of this is shown in Fig. 8.

Master Controller. The master controller is shown in Figs. 9 and 10. It has four control drums and four operating handles.

1. The speed drum, which controls the resistance switches and line switches; field shunts during motoring and the exciter voltage during regeneration.
2. The reverser drum, which performs the usual function.

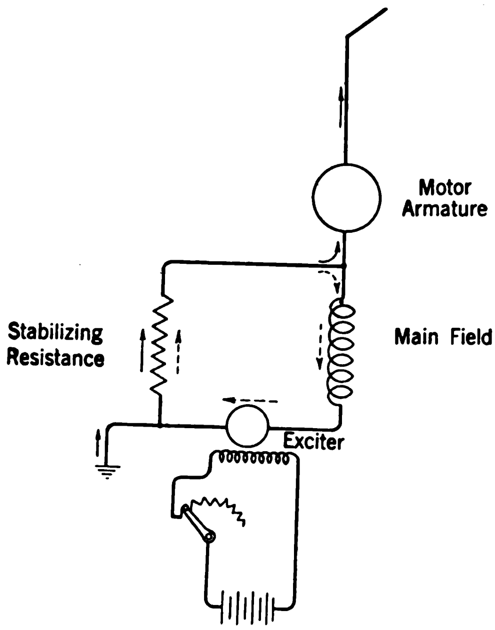

Fig 8—Simplified Schematic of Regeneration Connection

3. The motor combination drum, which has three positions, each corresponding to one of the three motor combinations.
4. The regenerative drum, which changes the connections from motoring to regenerating and vice-versa.

The master controller is arranged so that the controller may be thrown from the "off" position to the second or third speed combination, if desired, without passing through the lower combinations.

The method of operation is as follows:

To Start the Train. Motor combination lever in first speed position; regenerative lever in motoring position; the reverse lever in forward position.

Move the speed lever to the first notch and gradually notch up until the train starts and then continue until the resistance is all cut out and the train is running with the motor field shunted in the first motor combination.

Then throw the motor combination lever to the second position; back off the speed handle to the first position (at the same time pressing a button in the end of the lever so that it cannot pass the first position).

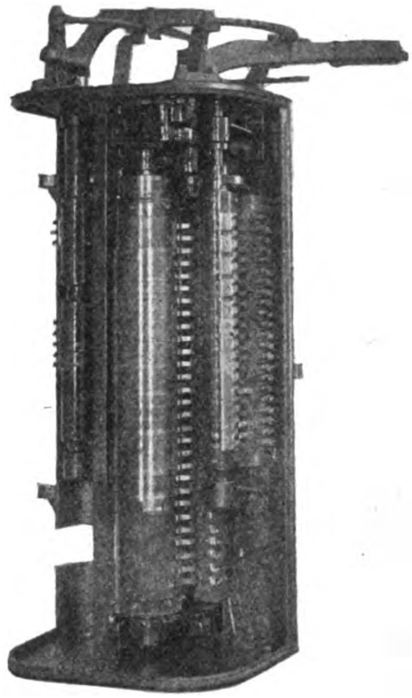

Fig. 9—Master Controller with Cover Removed, Showing Drums for Speed Control, Reversing, Motor Combinations and Regeneration

At that point, with the resistance all in circuit and the three legs of resistance in parallel, the change-over takes place; one-half of the motors being shunted momentarily and then thrown in parallel with the

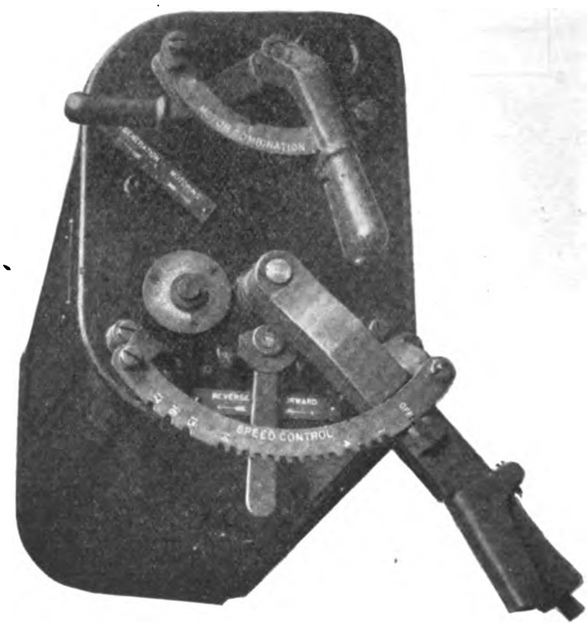

Fig. 10—Top View of Master Controller

other half. The resistance is then notched out as before and the motor-fields shunted.

Then the motor combination handle is thrown to the third position and the speed handle backed to the

fourth notch when the change is made from the second to the third combination, and the resistance speed handle again notched forward. With the resistance all cut out, the motors may be run with full field or first or second shunt.

The engine-man is prevented from accidentally starting the locomotive from rest, in the second or third combination, by an interlock in the controller which prevents the line switches from closing when the motor combination lever is in the second or third position, unless he pushes a button in the top of the master controller.

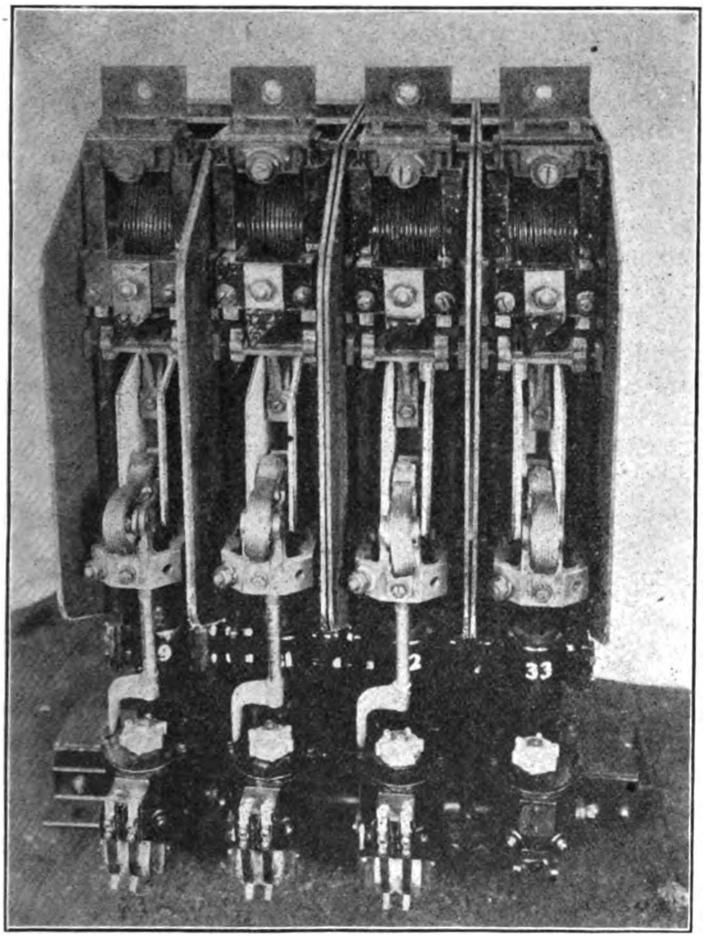

Fig. 11—Rear View of Group of Four High-Voltage Unit Switches

It is, therefore, necessary when applying current with the locomotive at speed, to press the button when it is desired to go immediately into the second or third combination.

There are thirteen resistance steps, all of which are available in both first and second speed combinations. On the third combination, there are ten steps that are useful; making a total of thirty-six resistance steps and two field shunting notches in each combination, or a total of forty-two steps in the master controller. The ease of manipulation of this arrangement of master controller has already been established in service.

Main Resistance. The main resistance is arranged in three groups, each of which has five switches, each short-circuiting a section of resistance. These three groups are connected all in series for the first combination, and three in parallel for the second and third combinations. The sequence of closing the resistance switches is the same on all combinations. The resistances are always connected in series before the master controller reaches the "off" position.

Overload Trips. The overload trips are arranged to open the resistance switches and insert the entire resistance in series before the line switches are opened.

Regeneration. The operation to begin regeneration is as follows:

1. Throw the regenerative handle to the regenerative position on the master controller.
2. Place the motor combination handle in position corresponding to the speed of the locomotive.
3. Move the speed lever to the first step. This connects the motors to the line with all resistance in series and with the motor-fields excited with the minimum exciter voltage.

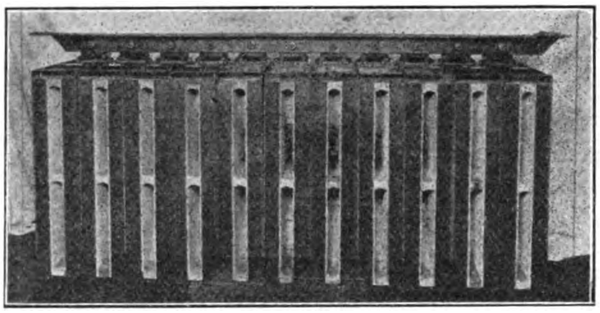

Fig. 12—Front View of Unit Switch Group

The exciter voltage is automatically increased until the motor voltage equals the line when the speed lever is moved to the sixteenth notch of the controller, after which the exciter voltage and speed can be changed by the engine-man by moving the speed handle alternately back and forth between the sixteenth and the seventeenth notches, if the exciter voltage is to be decreased; or between the sixteenth and the fifteenth, if it is to be increased. The motor-operated rheostat will move one step for each time the controller is moved.

To change the motor combination during regeneration, throw the speed handle to the "off" position; move motor lever to the new position and start regeneration as before.

Unit Switches. These are shown in Figs. 11 and 12, and are indicated on the diagram by two vertical dashes. The switches are numbered from "1" to "33". The switch is provided with a very powerful magnetic blowout with arc chutes of arc-resisting material, and an arc splitter. It is electro-pneumatically operated and is designed so that it is very thoroughly protected from insulation troubles and for ease of inspection and over-hauling.

Cam Switches. The cam switch groups are shown in Figs. 13 and 14, and indicated on the diagram by two vertical dashes enclosed in a circle. The switches are designated by numbers and letters. The number corresponds to the group in which the switch is placed and the letter corresponds to the particular switch in the group.

Those of Nos. 37 and 38, which are the groups operating the field shunts, also Nos. 39 and 40 which control the stabilizing resistance during regeneration, are provided with magnetic blowout; but the switches

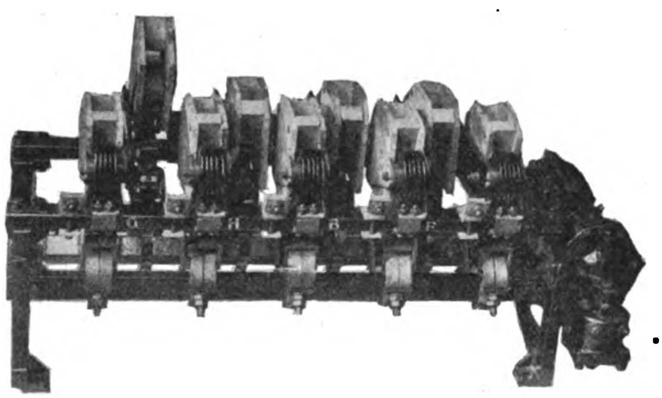

FIG. 13—CAM OPERATED SWITCH GROUP WITH MAGNETIC BLOWOUTS

for the reverser, which never close or open the circuit with current on, have no arc chutes or blow-outs. Groups Nos. 34 and 35, which make the different motor combinations, have barriers placed between adjacent switches which have a large difference in potential, but no magnetic blow-out, since these switches are never used for opening the circuit under load. The groups are operated electro-pneumatically.

Auxiliaries. Power for the auxiliary motors, control circuits, train lighting, motor excitation, etc., is derived from three sources:

1. *Motor-Generator.* (See Fig. 16). The motor receives current from the line; the generator delivers current at a constant voltage of 85. This is required primarily for train lighting.

2. *Storage Battery.* Of the MV-25 ironclad Exide type containing 38 cells. This battery has a capacity of 300 amperes for approximately one hour.

3. *Two Axle-driven Generators.* Which are designed primarily to furnish current for exciting the main motors during regeneration.

The storage battery is always available to supply current for locomotive lights, control circuits, and the air-compressor motor for short periods. When the locomotive is in service, the generator of the motor-generator set is always in parallel with the battery, and from this dual source is always taken the power for lighting the locomotive and train, control circuits, cab floor-warmers, small blower motors for inductive field shunts, boiler blower and exciting current for the axle generators. In addition, the current for the air-compressor motor is supplied from this dual service whenever the locomotive is standing still or regenerating.

The axle generators are, as stated, used primarily for exciting the main motors during regeneration. At other times, when the locomotive is in motion, the axle generators are automatically connected to the auxiliary circuits from which the compressor and main blower motors take power. At this time the voltage is automatically maintained at 90.

Air-Compressor. A two-stage compressor with intercooler, having a displacement of 150 cubic feet per minute, is provided. It is a double-acting, upright type, driven by an industrial type motor.

Blowers. Two blowers are provided to supply forced ventilation to the driving motors. They are driven by motors that are duplicates of the compressor motor.

Auxiliary Control. The axle generator circuits are shifted from one circuit to another by a group of the same type of cam operated switches as are used in the main motor circuits.

The field rheostats for the generator of the motor-generator set and the axle generators are operated by small motors. As the fields of the two axle generators are connected in series, only one rheostat is required for them.

The switches for controlling the blower and compressor motors and the high-voltage motor are magnetically operated.

The motor of the motor-generator set is protected from overload or short circuit by a small permanent

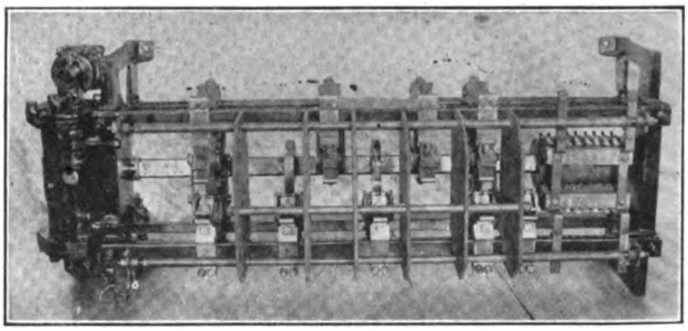

FIG. 14—CAM OPERATED SWITCH GROUP WITH BARRIERS

resistance in series and a set of three expulsion type fuses which blow in series, the first two inserting additional resistance in the circuit, and the last opening only after a relatively high resistance has been inserted and the current consequently limited to a low value.

Meters. A Sangamo wattmeter is provided which has separate dials for integrating the motoring watts and regenerating watts. A full set of motor ammeters is provided, and also a voltmeter reading line volts. An ampere-hour meter is provided for the storage battery.

Train-Heating Plant. A boiler with a capacity for

evaporating 4000 lb. of water per hour is provided for heating the train and engine-man's cab. The boiler and water storage tanks are located in the middle of the cab and occupy a relatively large proportion of the space. The tank for fuel oil is located directly beneath the boiler, and the water tanks, two in number, just fore and aft of the boiler.

Pantagraphs. Two pantagraphs of the double sliding shoe type are provided. These are raised by air and lowered by gravity.

Wiring. All cable is in steel conduit, and all exposed connections are solid copper bar or strap.

6. The minimum permissible restraint to free movement of each axle and portion of the running gear.
7. Large diameter of drivers and low "dead" weight on axles.

In designing a locomotive cab, it is very advantageous to concentrate the heavy equipment between the center pins. A good rule is to have the radius of gyration with the cab swinging from one center pin, shorter than the distance between center pins.

In the running gear, it is desirable to have the radius of gyration measured from the center pin, less than half the wheel base. The closer the weight is concentrated to the center pin, the less tendency there is to nose and the easier the duty on the wheel flanges and track. The steam locomotive seldom has a good fore and aft distribution of weight, but its high center of gravity compensates for it.

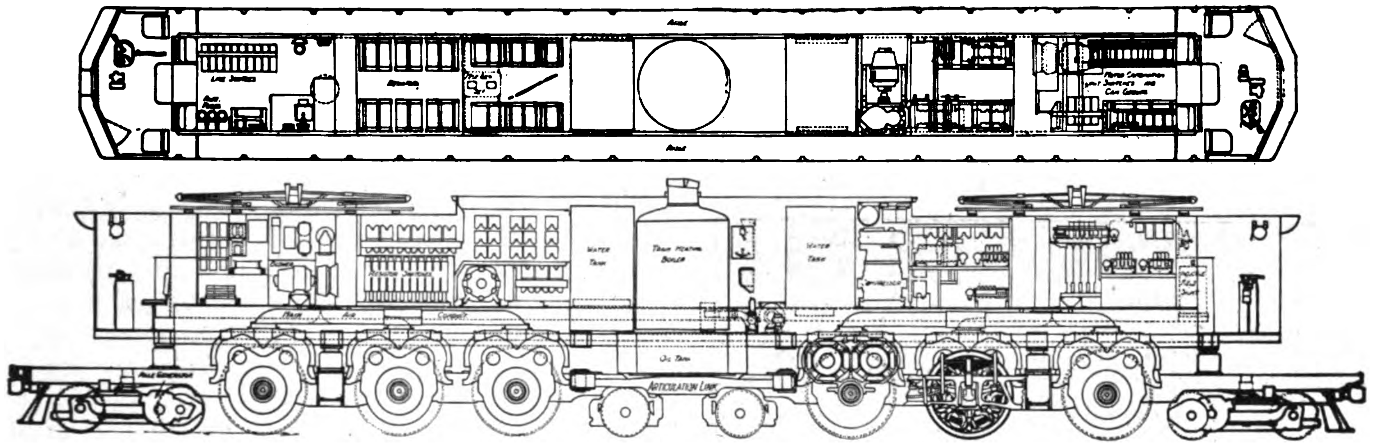

Fig. 15—Longitudinal Section of Locomotive

Mechanical Design. This locomotive has been designed to possess certain mechanical features which have developed through years of experience with steam locomotives. These characteristics are believed to be advantageous when applied to electric locomotive design as well. They may be summarized about as follows:

1. Distribution of weight, fore and aft, with respect to wheel base.
2. Height of center of gravity.
3. Length of rigid wheel base.
4. Guiding trucks.
5. Equalization.
6. Coupling between truck frames.
7. Diameter of driving wheels.
8. Non-spring-borne weight on driving axles, etc.

The principal means that contribute to good operation are:

1. The location of the mass of the locomotive as close to the center as possible.
2. High center of gravity of that portion of the locomotive carried on the running gear.
3. A long rigid wheel base to insure stability and also to decrease the transfer of weight due to drawbar pull.
4. Guiding trucks, located well outside the mass of the running gear, to contribute to stability, as well as leading the locomotive into curves.
5. Proper equalization to secure stability and weight distribution.

As concerns the size of drivers and dead weights,

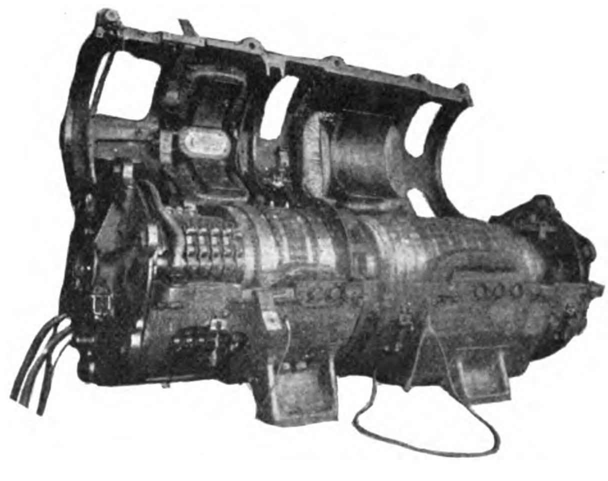

Fig. 16—3000-Volt-85-Volt Motor-Generator Set—Top Half Opened

it may in general be said that, other things being equal, the effect on track is inversely proportional to the square of the wheel diameter, and directly proportional to the dead weight.

This locomotive embodies all the foregoing features to a remarkable degree. Particular attention was given

to weight distribution. The cab has the boiler, water and oil tanks, storage batteries, air-compressor, resistors, motor-generator set, and the heavier parts of the control equipment, concentrated between the center pins. The driving motors are mounted above the axles on the running gear, thus getting the weight well inside the wheel base, but placing it relatively high. The height of the center of gravity of the complete locomotive is 68 in., a value that corresponds well with that of a steam locomotive.

The Pacific type of running gear with its long rigid wheel base and the guiding trucks is a particularly stable design and is especially good with the weight distribution that obtains on this locomotive. The height of the center of gravity of trucks with motors mounted is 43¾ in.

The quill drive, which is a further development of the one used on the New Haven locomotives, gives each driving axle perfect freedom to move vertically the full distance permitted by pedestal jaws without affecting the motors or frames, except through springs. The only "dead" weight carried is the weight of wheels, axles, journal boxes and spring clamps; a total of 7032 pounds for the wheels, axles and spring clamps which are rigidly fastened together, and 770 pounds for the journal boxes. This weight with the larger diameter of drivers (68 in.), and the total weight of 56,000 lb. per axle, gives a combination that is much better than has been considered very good practise on steam locomotives.

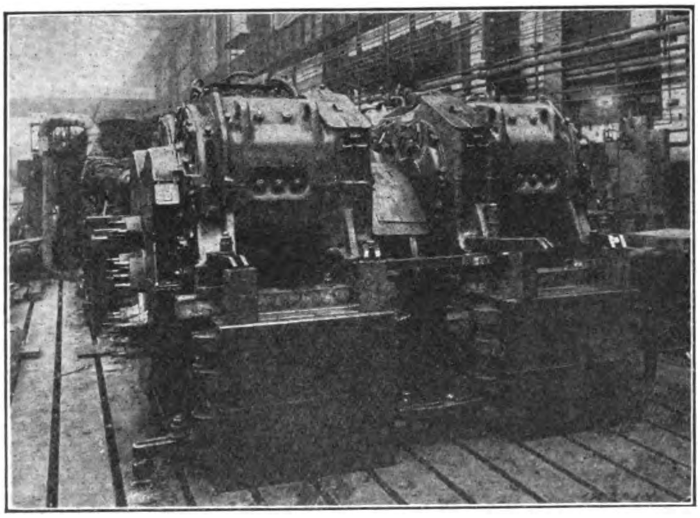

Fig. 17—Two 700-H. P. Motors Coupled Together for Test

Great effort has been made to cushion the locomotive against shock, either while running or from bumping. The apparatus in the cab is especially well protected since the cab rests on spring-supported plungers which are in series with the main semi-elliptic springs. The cab is protected against bumping strains by floating center pins, which, while held rigidly against lateral motion, are cushioned against longitudinal motion by heavy springs. It has been the practise heretofore with this general type of locomotive to have one center pin rigid in the running gear frame and allow the other one to move freely in a longitudinal direction. It is felt that it is much better to allow a slight relative motion between the two center pins, but to prevent the bumping shocks by spring cushioning.

Electrical Design

Main Motor. This was constructed of the twin armature type for several very good reasons:

1. The two armatures can both drive the same gear. A single armature motor would require twin gears, each of the same gear face as the present single gear in order to keep the tooth pressure down to the same value.

2. The space between wheels available for motors is limited and must be divided between gears and the motor itself.

The use of a second gear would take just that much space out of the armature core, and thus make a very large diameter necessary to get the output required.

3. A large diameter motor and double gears would increase the weight and cost of the locomotive.

4. A large diameter would make the motor extend farther up into the cab, thus necessitating raising the floor above the motors and cutting down the space available for other apparatus.

5. The use of two armatures makes it easy to design the motors so as to secure the advantages of low-voltage armatures for commutation.

6. Small armatures are easier to handle and cheaper to maintain than the large ones would be.

The capacity of the motor was fixed by the number of driving axles. Six driving axles were used as this seemed to be the smallest number that could be used with the limiting weight on the drivers. It was especially fortunate, as it led to the adoption of the double Pacific type of running gear with its excellent riding characteristics.

The characteristic curves of the motor, shown in Fig. 5 are taken from test; the efficiency being measured by the "input-output" method with all losses included. In making this test, two motors were connected together through gears, quills and quill springs; one motor being run as a motor, driving the other as a generator. See Fig. 17. The current from the generator was fed back through the motor by boosting its voltage, and the additional current required was supplied from an outside source. The measurements of the power supplied by the booster and from this outside source constitute the total losses in the two machines. The test was made on motors which had been operated only a few hours, consequently, the friction losses are probably higher than they would be after being in service for awhile; but the electrical and mechanical losses are thus included in the total, and the efficiency thus derived is the same as if the motors were on the locomotive. It is worthy of note that the efficiency

thus measured is materially higher than that calculated by the A. I. E. E. Rules from "no-load" losses and the fixed percentage of losses for gears and other load losses. These tests show plainly that those losses assumed for the Institute Rules are too high for large motors.

Fig. 4 shows the pinion end of the motor, and on the motor frame are shown the shields which protect the motor from melting snow falling into the outlet openings in the motor frame.

The motor armatures have very effective fans mounted on them which give the motors quite a high continuous rating without the use of any forced ventilation. It is expected that the blowers will not be used at all with normal train weight, except on heaviest grades.

Control. 1. The first thing necessary in designing the control for an electric locomotive is to decide on the combination of motors that is to be used.

2. To decide on the schematic arrangement of switches.

3. To decide on the necessary sequence of switches and arrange the master controller and suitable interlocks in the control circuit to insure following that sequence.

4. Calculate resistance values and the number of steps necessary to secure smooth control.

5. To design master controller, switches and other apparatus to meet these requirements.

6. To arrange overload trips so as to afford adequate protection from overloads and grounds in any part of the circuits, without producing dangerous voltage surges or serious arcing.

Where regeneration is to be provided for on a d-c. locomotive, it is essential,

1. To decide on a scheme that is inherently stable.

2. To arrange a schematic diagram of switches corresponding to the scheme, and to utilize as far as possible the same switches and sequence of switches as when motoring, so as to keep the total number of switches as low as possible.

3. To provide for beginning regeneration at any speed within the normal running range without having a heavy current in either direction that would produce a surge in the train.

4. To arrange the control so that the engine-man will have control of the regenerated power and speed at all times.

With six motors to drive the locomotive, some new problems were introduced.

The universal practise with d-c. motors heretofore has been to use the series-parallel arrangement, or at most, series, series-parallel and parallel, giving one-fourth, one-half and full speed. This scheme takes motors in multiples of two, or when two motors are connected permanently in series, in multiples of four.

With six motors and twelve armatures on 3000 volts, it would be possible to obtain the regular series-parallel control in several ways, had it been desirable.

1. A twin motor could have been wound for 3000 volts, and six motors then divided in three sets of two motors; each set being arranged for series-parallel.

With this arrangement, the motors would at least be less rugged and more liable to flashing than where they are wound for 1500 volts, and the control would be much more complicated.

2. The motors could be wound for 1000 volts each and connected permanently three in series.

This would give the simplest control; but connecting three motors on independent axles in series, would lead to dangerous over-speeding and two to three times the normal voltage on the motors in case of wheel slippage. It is common practise on high-voltage d-c. cars and locomotives to run with two motors permanently in series. The maximum voltage one can get in case of wheel slippage is less than double the normal voltage. This method has given very good results, but it is as high as it is safe to go with geared motors.

3. The motors could be wound for 2000 volts, that is, 1000 volts per armature, and three armatures connected permanently in series.

This would be open to the same objection from over-speeding and over-voltage on the motors whose armatures are in different circuits, and the motors would not be interchangeable, for some would have their armatures and fields connected in series inside the motors, and would thus have only four leads, while the others would have to have a separate set of leads for each armature and field winding.

In none of these three cases (except the second), would the control be materially simpler than the scheme that was finally adopted; but the best reason for the adoption of the one-third, two-thirds and full speed arrangement lies, not so much in any reasons that have been mentioned heretofore, as in the great advantage of the three-speed locomotive for handling the service. The one-third and the two-third speed arrangements cover the range so much better than the one-half speed, or than the one-quarter and one-half speeds, that there is scarcely any comparison possible. The half speed is too low for a running speed and too high for switching. The one-third speed is an excellent switching speed, and the two-thirds speed is a good running speed and is especially good for regenerating on heavy grades.

Another considerable advantage lies in the decreased rheostatic losses on this locomotive compared with one having the ordinary series-parallel control. The three speeds alone make a very considerable reduction in rheostatic losses; but when combined with the field shunting positions on each combination, reduce the rheostatic losses to less than one-half of what would be obtained with the ordinary series-parallel control. This, of course, means a very decided reduction in the weight of resistance necessary, as well as an increase in efficiency.

The combination of unit switches and cam switches gives a perfectly successful, and at the same time, the

lightest combination of switches possible. The unit switches are used in the high-voltage circuit wherever they are required to open the circuit with any current; thus the line switches, resistance switches and safety switches in the motor combination circuits are of the unit type and are interchangeable, except for interlocks which are easily transferred. The reverser switches, field shunt switches and those for regenerative change-over, exciter and auxiliary change-over are of the cam type, and operated by compressed air. These switches are assembled in groups of from four to sixteen switches; the sixteen-switch group being the reverser.

Shunt transition is used in passing from one motor combination to another as it is simple and gives sufficiently smooth transition to be very satisfactory. In changing from the first to the second combination, one-half of the motors are shunted momentarily; but in going from the second to the third speed, only one-third of the motors are shunted.

The sequence of switches is so simple that relatively few of the unit switches have interlocks on them, but the cam groups are all interlocked so that it is impossible to get false operation. The switches in any given cam group have the mechanical interlock provided by the cam shaft.

One of the fundamental principles on which this locomotive was designed was that the motor circuit should not be opened, either in normal operation or under emergency, until the current had been cut down by the introduction of resistance.

The specifications describe how this is done on this locomotive. It is considered to be a very valuable, if not an absolutely necessary, feature. It not only divides the arcs among a large number of switches and, therefore, promotes safety, but it prevents the generation of high voltages from suddenly rupturing a heavy current.

The line switches are located in a separate compartment from the resistance switches so that the four switches in series are always kept free for the final break.

Another fundamental principle in the regeneration was that the motors should never be connected to the line without the maximum starting resistance in series between motors and the line. This is a valuable provision in motoring, but is necessary in regeneration to prevent undesirable surges in the train.

This locomotive has approximately 17 ohms of resistance on the first step, consequently, the maximum current that could flow from the line would be less than 200 amperes, if there were no voltage generated in the motors at all. If this current is divided between two or three circuits, as would be the case on the second or the third combinations, the torque resulting, especially with the very small current in the motor field, would be negligible. The exciter rheostat is so arranged as to increase the voltage of the exciter immediately on closing the line switch until the flow of current through the resistance is practically zero, which means that the voltage of the motors equals that of the line. This method gives perfect safety in connecting the motor to the line and the stabilizing resistance and the axle-driven exciters add still more to the safety.

The stabilizing resistance protects the motors against sudden changes in line voltage, while the axle-generators protect against variations in grade, which would otherwise tend to vary the speed.

In case of a sudden reduction in line voltage, which would be followed by a heavy increase in the regenerated current, the increased voltage drop in the stabilizing resistance resulting from this, immediately cuts down the field current and generated voltage of the main motor sufficiently to limit the increase in regenerated current to a safe value.

In the case of the passage of a train from a sharp curve on a compensated grade to a tangent, there would be a tendency for a sudden heavy increase in speed, because of the steeper grade and the decrease in train resistance. As the speed increases, the voltage of the axle-generators automatically increases and, therefore, the field current of the main motors, which holds the train with a very slight increase in speed.

This scheme of regeneration offers a high efficiency as the only extra losses are those in the exciter and in the stabilizing resistance, both of which are small.

Auxiliaries. It has been the experience with high-voltage d-c. equipments that the auxiliary motors are very much more difficult to design than the main motors. More trouble is ordinarily experienced with auxiliaries than with the main current apparatus and in order to make such apparatus reliable, a great deal more expense is involved than would normally be warranted. It was the policy on this locomotive to limit the high voltage to the minimum possible number of circuits and the minimum amount of apparatus. It was impossible to avoid it altogether on the moving apparatus, due to the fact that the train lighting must be supplied for hours at a time in case of any emergency when the train is held up by a wreck or because of storms. The motor-generator set, which is designed primarily for this purpose, is the only piece of moving apparatus among the auxiliaries which has the high voltage applied to it. The voltage selected for the auxiliary circuits was primarily decided by the voltage required for train lighting. While 85 volts is lower than would otherwise be selected for the auxiliary motors, it is perfectly safe and is a voltage that is so low that the motors can be forgotten, as far as the questions of insulation and commutation are concerned. The auxiliary motors are, of course, very much smaller than would be the case, if the high voltage were applied to them.

A storage battery, from the standpoint of operation, is always a desirable thing on the locomotive as it

offers an opportunity for making a complete inspection of control apparatus by furnishing current for the lights and control, and for keeping up the air pressure without having the high-voltage current on the locomotive at all. Having a source of power to furnish light on the locomotive is a very desirable feature.

The combination of the storage battery and the axle-generators will furnish ample auxiliary power to take a locomotive to the end of a run, if the motor-generator set fails. The same combination will take a train safely down the longest and steepest grade with the air-brakes, if power is for any reason cut off the line. If the train is going up a grade and power is cut off, the battery will furnish air to hold the train with the brakes for a considerable time, so that it will not be necessary to block the wheels as is the ordinary practise, unless power is off for a considerable time.

Low-voltage motors are so small, comparatively speaking, that although there is a great difference in the power required for the compressor and the main blower motors, it was felt that the advantage of having the motors interchangeable was worthy of the increase in cost of the blower motors. The design of the compressor adopted is favorable to this, so that the motor is practically a standard industrial type of motor.

Thermostat. The thermostat, which is used for starting the blower motors, in accordance with the requirements, consists simply of a cast-iron resistance made up in tubular form, which is in series with the main motor armature. This resistance is enclosed by several micarta tubes so that it has substantially the same thermal characteristic as the main motor. There is a Sylphon tube contained within the resistance tube, which expands when a predetermined temperature is reached and closes the magnet circuit of the blower motor switch, thus starting the blower when that temperature is reached. The apparatus is very simple and rugged; and while, of course, it cannot follow the temperature of the motor absolutely, it is sufficiently accurate for the purpose.

Conclusion

The initial operation of these locomotives has given every reason to anticipate that good riding qualities, the advantage due to low-voltage auxiliaries, the flexible speed control, stability of regeneration, safeguards against short circuits, and the simplicity and ruggedness of the individual parts of the locomotive, form a combination that will be a great success in the service for which it was designed.

CLASSIFICATION FOR SUBJECTS IN RADIO SCIENCE

The radio laboratory of Bureau of Standards, Dept. of Commerce, has, in common with other workers in the radio field, felt the need for a systematic scheme of classification for subjects in radio science and engineering. This need is felt not only for use in classifying the references to current radio publications, but also for classifying other radio material such as drawings, books, miscellaneous reports, etc. The Bureau has made a step toward filling the need for such a classification by preparing an outline, the principal divisions of which are given following.

The entire subject of radio is divided into eleven classes, in addition to which are listed two classes which are related to radio. In the complete outline under each of these named classes are listed the divisions into which the material would seem to be logically divided. Undoubtedly, there are other divisions which it would be advisable to list and it may be that some of the headings given in this classification should be combined.

The Bureau desires to make this list as complete and comprehensive and especially as usable as possible, and would, therefore, appreciate any criticisms or comments. For complete outline or in submitting criticism, etc., address, Bureau of Standards, Dept. of Commerce, Washington, D.C.

Classification of Radio Subjects. A, Radio Wave Phenomena. B, Antennas. C, Electron Tubes. D, Radio Measurements. E, Properties of Materials. F, Radio Theory. G, Radio Research. H, Radio Instruction. I, Miscellaneous Radio Apparatus and Methods. J, Radio Communication and Applications. K, Radio Micsellaneous. L, Electrical Subjects Related to Radio. M, Miscellaneous.

NAVY APPROPRIATION BILL

Original estimates in this measure amounted to $573,131,254, which were pruned in committee to $425,289,574, and reported to the House March 18th. The bill carried a recommendation that the "Bureau of Steam Engineering" be changed to "Bureau of Engineering." It will have charge of all the Navy's electrical work as well as practically all classes of engineering work in connection with the use of steam. This Bureau is recommended for an appropriation of $28,000,000. The bill specifies among other things that the above amount is to be expended for "repairs, preservation and renewals of electric interior and exterior signal communications and all electrical appliances of whatsoever nature on board naval vessels except range finders, battle order, and range transmitters and indicators and motors and their controlling apparatus used to operate the machinery belonging to other bureaus; searchlights and fire-control equipments for anti-aircraft defense at shore stations; maintenance and the operation of coast signal service and instruments, apparatus, supplies, technical books, and periodicals necessary to carry on experimental and research work in radio telegraphy at the naval radio laboratory."

Passenger Locomotives for Chicago, Milwaukee & St. Paul Railway

BY A. F. BATCHELDER
Ry. Locomotive Dept., General Electric Co., Schenectady, N. Y.
AND
S. T. DODD
Ry. & Traction Engineering Dept., General Electric Co., Schenectady, N. Y.

DECEMBER 9th, 1915, may be considered the date of the initial electrical operation over the electrified lines of the Chicago, Milwaukee & St. Paul Railroad. During the following winter the electrification was extended over 440 miles of route from Harlowton, Montana, to Avery, Idaho, a section which crossed the Belt Mts., the Rocky Mts., and the Bitter Roots. The locomotives for this initial electrification were of the geared type, designed and built especially with a view to the most economical operation of the freight service. The locomotives for passenger service differed from the freight locomotives only in the details where it was absolutely necessary to meet the operating requirements, such as changing the gear ratio to increase the speed and providing car heating and lighting equipment.

Three years later, in 1918, the successful operation of the original equipment had convinced the railroad company of the economical advantages of electric operation, and they decided to equip an additional section extending over the Cascade Mts. between Othello, Washington, and Tacoma, Washington, a distance of 212 miles. In choosing the equipment for the new extension, it was decided to give special emphasis to the requirements of passenger service and to purchase locomotives which were primarily designed with this in view, taking advantage of any details which would assist in the proper and economical operation of passenger trains. For the freight service it was decided to retain the geared locomotives that were in use on the Harlowton-Avery Division, changing the gear ratio where necessary to meet freight conditions, and using only locomotives of the new design for passenger service.

To meet the specification for passenger locomotives, the General Electric Company has designed, completed, and tested, a locomotive which appears to embody the necessary qualifications and to successfully fulfill the requirements, both from electrical and mechanical standpoints. In designing the locomotive, particular attention has been given to the features affecting safety, reliability, efficiency, convenience of operation, effect on track, and cost of maintenance. The locomotive has especially good riding qualities; it has no apparent effect on the alignment of the track, and to a marked degree, it is free from transverse movements or oscillation which would tend to create lateral pressures against the rails.

Presented at the Pittsburgh meeting of the A. I. E. E., March 12, 1920.

It is the intention of this paper to give a description of this locomotive which differs in many ways from the locomotives which are now in operation on the Harlowton-Avery Division, to indicate the reason for choosing this design, and to call attention to some of the principal features which differ from usual practise. Briefly stated, the service requirements for the locomotive are to operate a 950-ton passenger train over the mountain divisions of the Chicago, Milwaukee & St. Paul Railway at speeds of 25 mi. per hr. up 2 per cent grades with maximum operating speeds of 60 mi. per hr. on the level, and to provide regenerative braking on the down grades at speeds consistent with safe operation. Fig. 1 is a photograph of the locomotive in three-quarter view. Fig. 2 is an outline drawing of the side elevation, giving the general dimensions. Fig. 3 is a section through the apparatus cab, showing the location and arrangement of the principal pieces of apparatus.

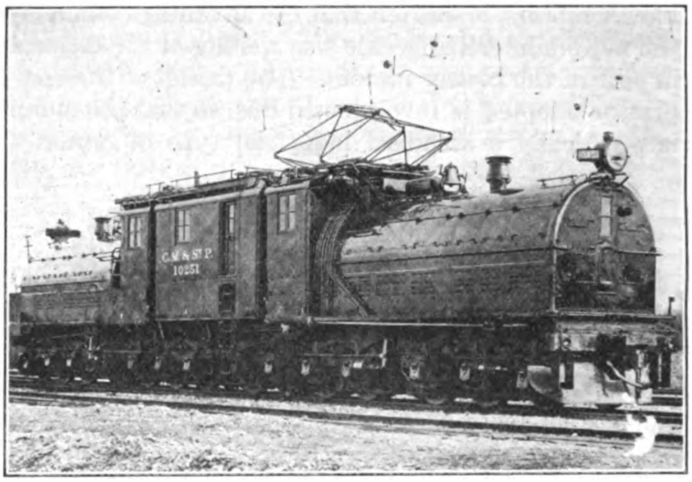

FIG. 1—THREE-QUARTER VIEW OF LOCOMOTIVE

It will be seen that the running gear is composed of four individual trucks; two end trucks having three axles each, and two center trucks having four axles each. These trucks are connected together by special articulation joints. The motor armatures are mounted on the axles and the motor fields are carried on the truck frames.

The superstructure is made in two sections of similar design with a third section between them. The third or central section contains the train heating equipment, which consists of an oil fired steam generator, together with water and oil tanks. This unit is complete in itself, and is carried over supports attached to the two

middle trucks. It can be readily removed for repairs without interfering with any other part of the locomotive. It is placed between the two operating cabs in order to be easy of access to the engineer's helper or fireman, from either location.

The two end sections are similar to each other in appearance. The operator's cab in either section is on the inner end next to the heater cab above described, in order that the operator can be convenient to the heater and in order to allow a maximum space for apparatus in the apparatus cab or outer end section. Another advantage of this arrangement of cabs is that the operator can have access to any section of the locomotive requiring his presence without passing through a section containing high-tension apparatus. The engineer's or operating cab contains a main or master controller, the air brake valves and handles, and an instrument panel, containing air gages, ammeters, and speed indicator. The engineer uses either of the two operating cabs according to the direction in which he is running.

A door gives access from the operating cab to the apparatus section which extends with a cylindrical top to the extreme end of the locomotive. The cylindrical construction naturally adapts itself to the protection of the apparatus included and in addition to this, it has the advantage of allowing a clear vision for the operator from his normal operating position. Contained in this apparatus section are the resistors and contactors to control the power circuits of the locomotive. The starting resistors are placed in two rows on each side of the central passage just above the floor of the superstructure and are covered at the sides by removable covers which when opened will allow the separate resistor boxes to be slid out upon the longitudinal running board outside of the apparatus cab. The air compressor for the air brakes, the motor-generator set for train lighting, and the storage battery for marker lights and emergency control, stand upon the same level as the resistors, and can be removed or replaced in a similar manner. Above the resistors are located the contactors with their arc chutes facing a central aisle two feet wide. This allows ample arcing space and room for inspection of contactors. Above the contactors is the cylindrical roof of the locomotive with trap doors for inspection of the back connections and insulation and for removing the contactors in case replacement is necessary. The whole design and arrangement of this apparatus cab lends itself to a maximum economy of cost and material, as well as to convenience of inspection and repair of apparatus.

Motors

The motors are of the well known bi-polar gearless design which were adopted by the New York Central Railroad 14 years ago, and which have proved by fourteen years' service, operating heavy passenger trains between Grand Central Station and Harmon, to be well suited for the service. This motor has demonstrated its remarkable reliability and low cost of maintenance.

To insure light weight per axle, flexibility in control, good truck arrangement for curving as well as for high-speed running, twelve motors are chosen, each of relatively small capacity. They are especially designed to withstand high temperature, being insulated with mica and asbestos.

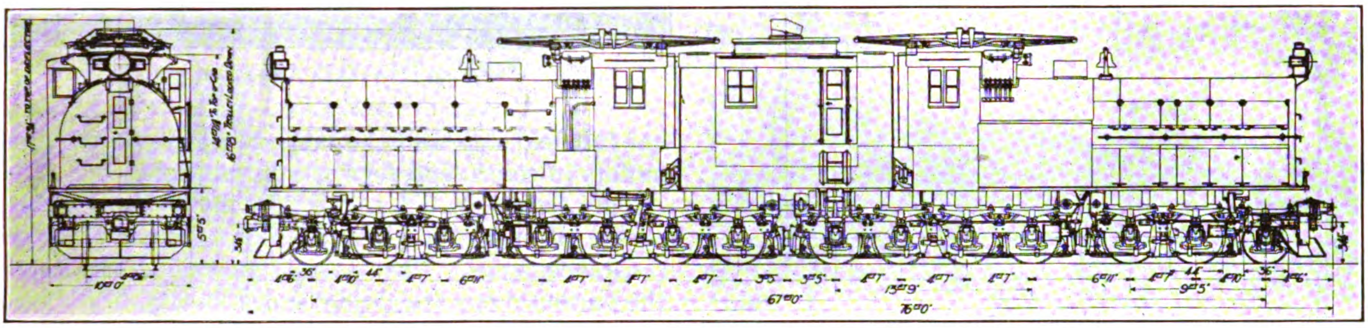

Fig. 2—Outline Drawing and Dimensions of Locomotive

Fig. 4 shows the motor armature complete, built directly on the axle with the wheels pressed and keyed in place. The continuous rating of each motor at 1000 volts and with 120 degrees rise by resistance is 266 h.p., corresponding to 3500 lb. tractive effort at the rim of the drivers at a speed of 28.4 mi. per hr. Forced ventilation is employed for cooling. The armature core is provided with holes for the passage of ventilating air. Ventilating blowers are located above each motor armature and deliver air at the commutator end of the motor where it divides, a part passing through the armature and a part back through and around the field coils where it escapes upwards and is afterwards used for ventilating the starting resistors.

This type of motor gives very high power efficiency in average operation, it having no journal bearings or gearing. It lends itself nicely to simple and compact locomotive design as the frame is made use of to furnish the entire path for the magnetic flux. The pole pieces and field coils are fastened to the cross transoms of the trucks and the magnetic flux passes horizontally in series through all twelve motors, finding a return path through the locomotive frame. The articulation joints between the trucks are made in such a manner that large surfaces are in contact to provide an easy

path for the flux. The pole pieces are made flat in order to prevent the pole pieces from coming in contact with the armature during the vertical movement of the truck frame on its springs or when removing or assembling the armatures. A minimum clearance of ⅛ in. on each side is allowed between the armature and the pole piece tips. The brushholders are bolted to the transom allowing the brushes to move up and down with the fields as the frame rides on the truck springs.

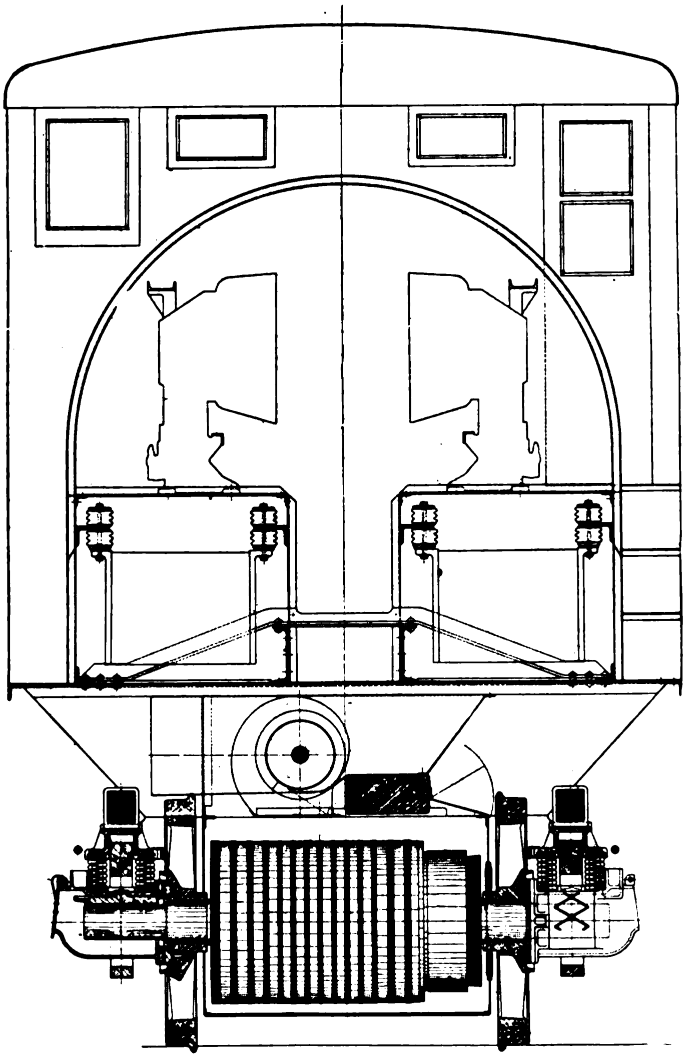

FIG. 3—CROSS-SECTION OF APPARATUS CAB

CONTROL

In choosing the control apparatus special care has been taken to use individual pieces of apparatus best suited to the particular requirements. Where single independently operating switches are necessary as on the resistance notches, electro-magnetic control is used. Where several switches are required to operate at one time as in changing from series to parallel motor connections, banks of switches with electro-pneumatic cam control are used, thus insuring positive operation, eliminating interlocks, and simplifying the wiring.

The control for motoring is arranged for four motor combinations.

The first combination has nine rheostatic steps, one full field step, and one tapped field step, with twelve motors in series across 3000 volts.

The second combination has six rheostatic steps, one full field step, and one tapped field step, with six motors in series and two sets in multiple.

The third combination has eight rheostatic steps, one full field step, and one tapped field step, with four motors in series, and three sets in multiple.

The fourth combination has eight rheostatic steps,

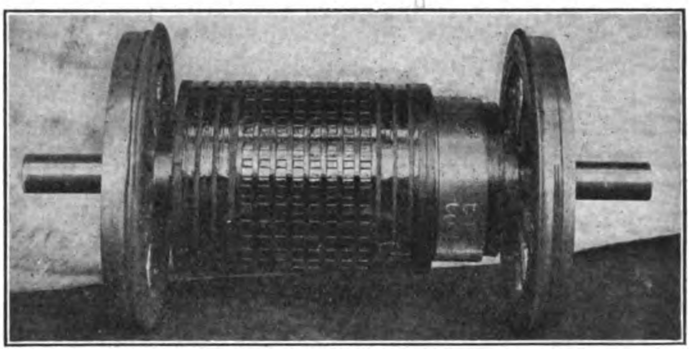

FIG. 4—BI-POLAR GEARLESS ARMATURE AND WHEELS

one full field step, and one tapped field step, with three motors in series, and four sets in multiple.

This results in a total of 39 control steps with a choice of eight operating speeds, exclusive of the resistance steps. The locomotive characteristics on the various steps are clearly shown in Fig. 5.

The regeneration of power for braking is accom-

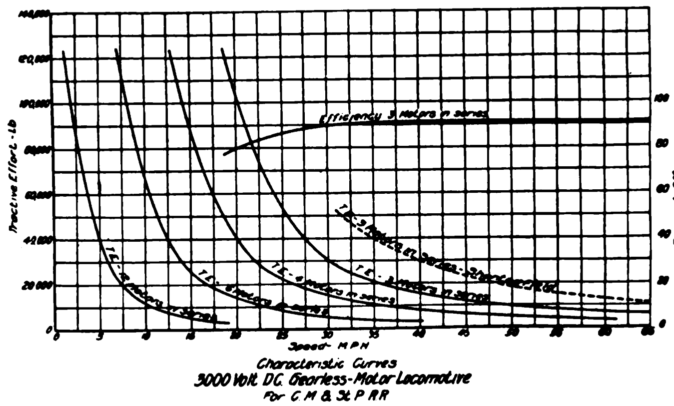

FIG. 5

plished in a simple manner by using some of the motors for exciting the fields of the others, which in turn are used as generators to return power to the line.

As a provision against short circuits, or extreme overloads, a quick acting circuit breaker is provided in the apparatus cab which will protect the circuit in less than 1/100 of a second.

MECHANICAL CONSTRUCTION

For flexibility in curving, the running gear is made up of four trucks, each of a relatively short wheel

base. The two middle trucks have four driving axles each; and the two end trucks, two driving axles and one guiding axle each, making a total of 14 axles. The trucks are connected together with articulated joints which allow of no relative lateral movement between them, so that each truck positively leads the following truck. This is for the purpose of reducing flange wear on curves and lateral oscillation on tangent track.

The most important problem that has to be faced in the design of a locomotive for high-speed passenger service is the problem of limiting as far as possible the lateral oscillations of the locomotive structure which tend to distort the track, and to minimize the effect on the track of such oscillations as occur. If a locomotive were built with a rigid wheel base as long as the total wheel base of the present locomotive (67 ft.), the lateral oscillations could not reach any large angular value. However, on account of the long wheel base, such a locomotive would be incapable of taking curves. By articulating the wheel base, as we have done, the locomotive is capable of accommodating itself to track curvature,

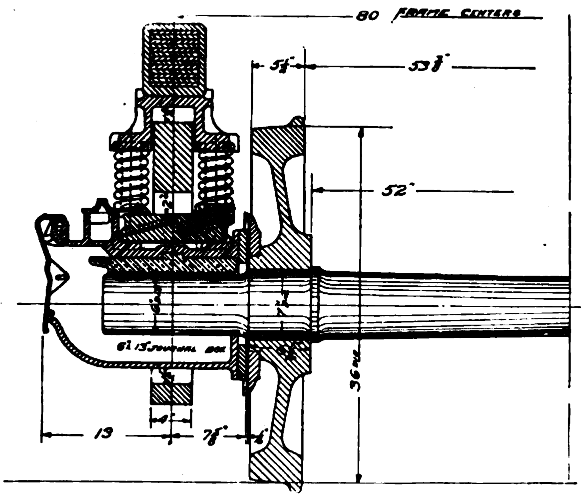

Fig. 6

but at the same time, on account of the articulation between trucks, and the consequent guiding effect of one truck on another, the lateral oscillations on tangent track are minimized in the same manner as would be done by the use of a long rigid wheel base.

To soften any lateral blow that may be given against the rail, the leading and trailing axles are allowed a movement of one-half inch relative to the truck frame, either way from their central position. This movement takes place against a resistance introduced by wedges above the journal boxes which tend to hold the box in its central position and to give a dead beat action opposing the motion. This wedge construction is illustrated in Fig. 6. To further protect the track from lateral displacement on the ties, the outer end of the superstructure is carried on rollers, bearing on inclined planes upon the truck frames, while the inner end of the superstructure is rigidly fastened to one of the middle trucks. This construction tends to hold the leading and trailing trucks in their central position. When a blow is delivered by the leading or trailing truck against the rail head, the superstructure, is displaced laterally across the outer truck. In such a sideways displacement, the weight of the superstructure rolls up on the inclined plane on that side, and thus transfers weight to the rail that is affected and increases the adhesion of the rail to the tie. This action really has two results. It not only increases the holding power between rail and tie at that point, but it introduces a time lag and increases the time and distance during which the pressure is delivered to the rail head.

As a matter of record, it should be said that the first of these new locomotives was delivered to the railway company at Deer Lodge, Montana, on December 14th, 1919, and was put in operation handling passenger trains between Deer Lodge and Avery.

For convenience of reference a table is attached giving a summary of the principal dimensions and characteristics of this locomotive.

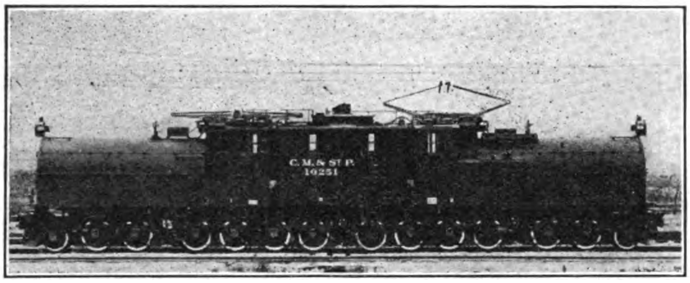

Fig. 7—Side View of Complete Locomotive

Total weight	521,200 lb.		
Total weight on drivers	457,680		
Weight per driving axle	38,140		
Dead weight per driving axle	9,590		
Weight per idle axle	31,750		
Dead weight per idle axle	3,560		
Length overall	76 ft.	0	in.
Width overall	10 ft.	0	in.
Height over cabs	14 ft.	11⅝	in.
Height over pantograph, locked down	16 ft.	8	in.
Total wheel base	67 ft.	0	in.
Max. rigid wheel base	13 ft.	9	in.
Diameter of driving wheels	44 in.		
Diameter of idle wheels	36 in.		
Size of journals	6 in. by 13 in.		
Dimensions of operator's cab	5 ft. by 10 ft.		
Dimension of heater cab	14 ft. 11 in. by 10 ft.		
Heater capacity	4,000 lb. steam per hr.		
Water capacity	30,000 lb.		
Oil capacity	6,000 lb.		
Compressor capacity	150 cu. ft. per min.		
Number of motors	12		
Type of motor	(bi-polar) GE—100		
Diameter of armature	29 in.		
Clearance between bottom plate and top of rail	5¼ in.		
Working range of pantograph	9 ft.	0 in.	
Locomotive Rating	*Tapped field*	*Full field*	
Total horsepower, 1 hr. motor rating	3,480	3,380	
Total tractive effort 1 hr. motor rating	36,000	46,000	
Speed mi. per hr	36.2	27.5	
Total horsepower continuous	3,200	3,200	
Total tractive effort continuous	32,000	42,000	
Speed, mi. per hr	37.8	28.4	

Flashing of 60-Cycle Synchronous Converters and Some Suggested Remedies

BY MARVIN W. SMITH

Westinghouse Elec. & Mfg. Co., East Pittsburgh, Pa.

WITH the increasing application of 60-cycle synchronous converters to railway service, the question of flashing is receiving considerable attention. A series of tests has recently been made, and others are still in progress, with a view to determining the possibilities of protection from flashing by various methods, including the "quick-acting breaker," "flash suppressor," "flash guards" and various modifications and combinations of these. The converter that has been used for these tests is a standard 500-kw., 600-volt, six-phase, 60-cycle, 1200-rev. per min. machine. It was supplied with power from a 5000-kv-a. generator through three standard high-reactance transformers. These transformers had a reactance of approximately 17 per cent at normal load and 10 per cent on short circuit.

An interesting and rather surprising feature shown by the tests is the extremely rapid rate of increase of the direct current on short circuit as compared with direct-current generators. For example, tests made on the generators of the 2000-kw. sets for the Chicago, Milwaukee and St. Paul Railroad, show the initial rate of increase in current on short circuit to be approximately 1,100,000 amperes, or 1650 times full load, per second. Also short-circuit tests on a 1000-kw. 600-volt direct-current generator show an initial rate of increase in current of approximately 2,700,000 amperes, or 1620 times full load, per second. On the 500-kw. converter, however, the average initial rate of increase is approximately 3,300,000 amperes, or 4000 times full-load current per second. This large difference between the rates of increase of short-circuit current for the d-c. generators and the converter cannot be accounted for by the difference in the inductances of the machines. In fact, the calculated inductances of the generators, which are of considerable lower frequency than the converter, are lower than the calculated inductance of the converter. The difference may be due to the fact that the alternating current which is a motor current building up in the opposite direction from the direct current, produces, or tends to produce flux linkages in the armature winding which oppose those of the direct current, with the result that the induced voltage opposing the rise of direct current is reduced. In other words, a higher rate of increase in current is necessary to produce the required counter voltage, which accounts for the higher rate of increase in current in a synchronous converter than in a direct-current generator. Reference to oscillogram Fig. 1 shows that the current reaches its maximum value in approximately 0.006 seconds. This rapid increase in short-circuit current together

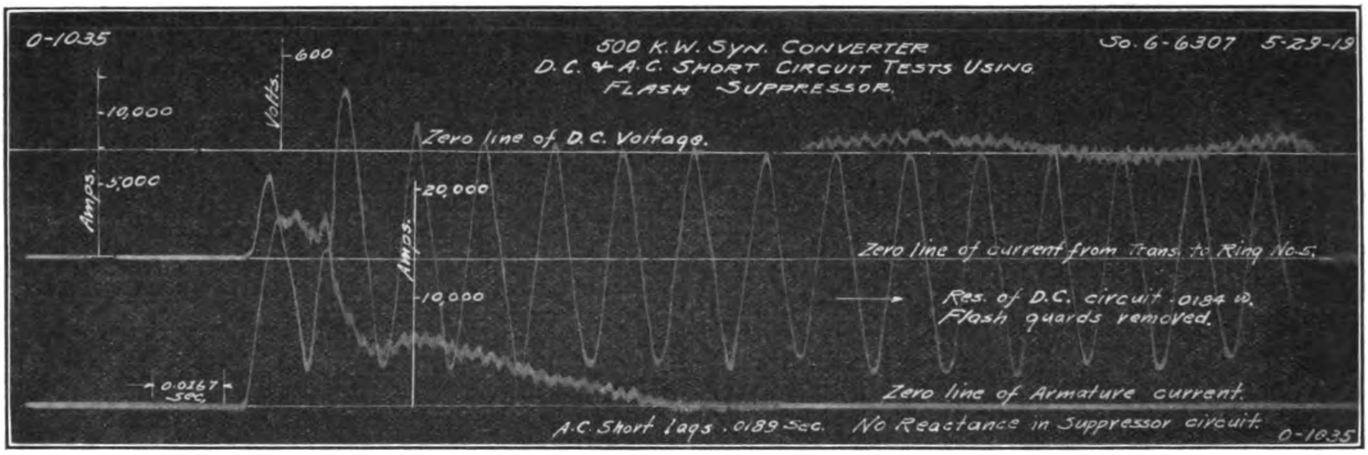

FIG. 1

Reasons why 60-cycle converters are susceptible to flashing. The protection of the 60-cycle converter is more difficult than the protection of any other class of commutating machines due to the inherent limitations of distance between neutral points on the commutator. The limiting distance between neutral points is fixed by the frequency and peripheral speed of the commutator. For instance, considering the maximum allowable peripheral speed as 5500 feet per minute, the distance between neutral points in the case of a 60-cycle machine will be approximately 9.2 inches regardless of the speed or number of poles. This may be readily seen from the following simple relation:

$$\text{Dist. between neut. points} = \frac{\text{circum. com.}}{\text{poles}}$$

$$= \frac{\text{periph. speed}}{\text{rev. per min.} \times \text{poles}} = \frac{\text{periph. speed} \times \text{poles}}{\text{poles} \times 120 \times \text{freq.}}$$

$$= \frac{\text{periph. speed}}{120 \times \text{freq.}}$$

Presented at the Pittsburgh Meeting of the A. I. E. E., March 12, 1920.

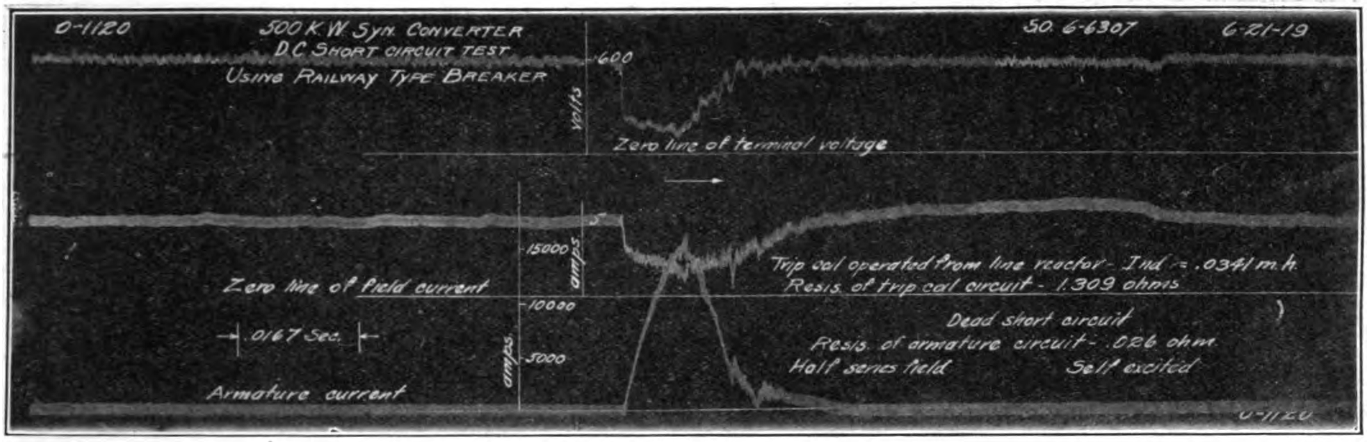

Fig. 2

with the limited distance between brush-holder arms, makes the 60-cycle converter particularly susceptible to flashing trouble.

Conditions Causing Flashing

Flashing does not appear to be entirely dependent upon the point or value at which the current is arrested. Oscillograms in Figs. 2 and 3 show dead short circuits on the machine when protected by a modified high-speed railway-type breaker. The current was limited to approximately 14,500 amperes, 17½ times full load, the rate of current increase being limited to some extent by the use of a small reactor as a shunt for the trip circuit of the breaker. (The maximum short-circuit current value of this machine is approximately 19,000 amperes or about 23 times full load). However, at this speed the machine was completely protected, except for slight pitting of the brush holders, even at this high current value. The voltage records show clearly that the machine cleared itself immediately after the complete opening of the breaker, which took place in approximately 0.015 seconds. Fig. 4 shows an overload only one-fifth the above value in connection with the ordinary low-speed breaker, from which it is evident that the machine bucked over immediately after the breaker opened even at this lower value of current. When a machine is on short circuit a large percentage of the voltage is consumed internally. The heavier the short circuit the larger is the percentage of the voltage thus consumed. Then so long as the d-c. breaker is closed the voltage between brush arms and hence the tendency to flash is a minimum. The voltage between neutral points on extreme overload and short circuit with the d-c. breaker closed, is also dependent somewhat upon the brush pressure. The higher the brush pressure the lower the contact drop and hence the external voltage between neutral points. This contact drop may be quite appreciable if the brush pressure is low enough to allow the force of the arc to lift the brushes off the commutator, which means a lower percentage of the voltage will be consumed internally, with a result that the voltage on the commutator will be higher. Assuming a reasonable brush pressure and contact drop, it is practically impossible for a machine to buck over and hang on between arms on dead short circuit so long as the d-c. breaker is closed, for the voltage on the commutator is practically killed just in the same manner as in the case of the flash suppressor referred to later. It is usually the opening of the d-c. breaker that does the damage. Tests in connection with both the low-speed and high-speed breakers and, in fact, ordinary operating experience show that a machine rarely bucks over until the d-c. breaker opens. See Figs. 4, 5 and 6. There

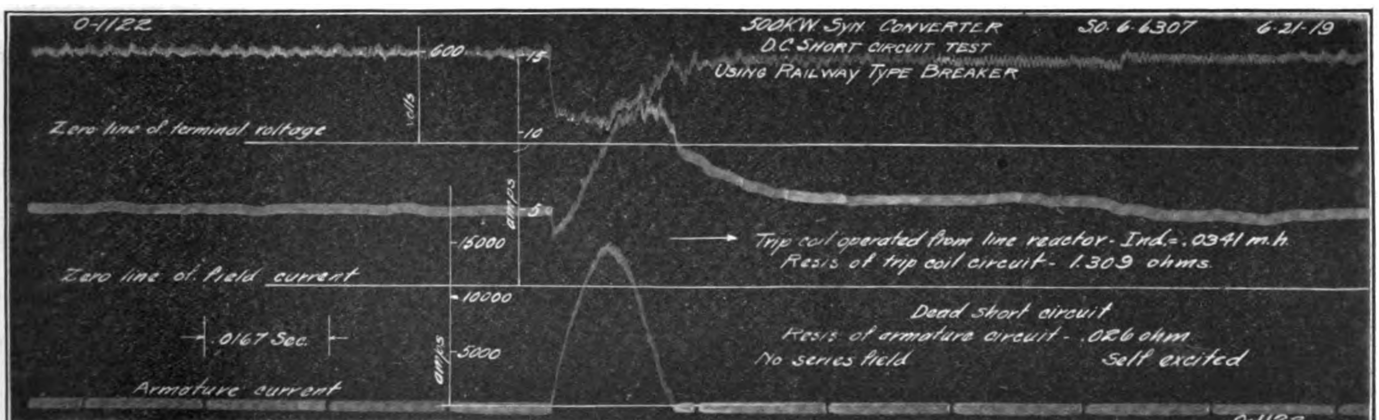

Fig. 3

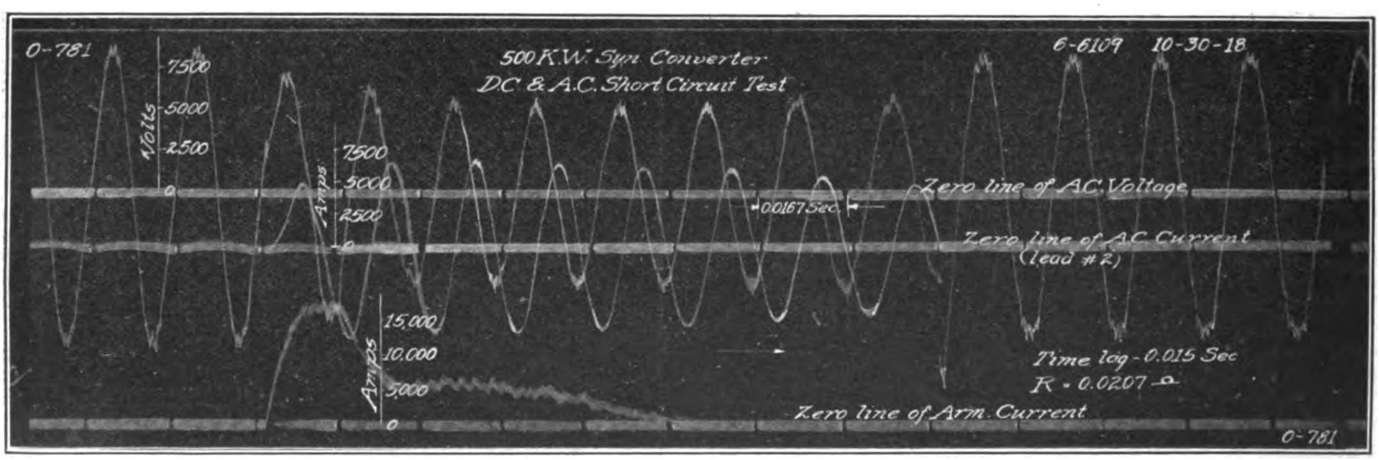

Fig. 7

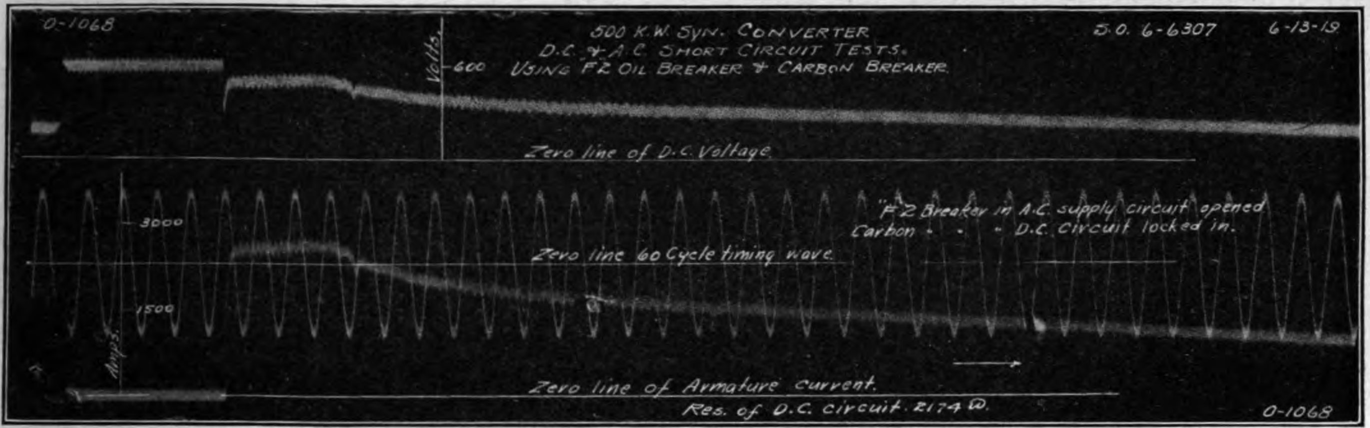

FIG. 8

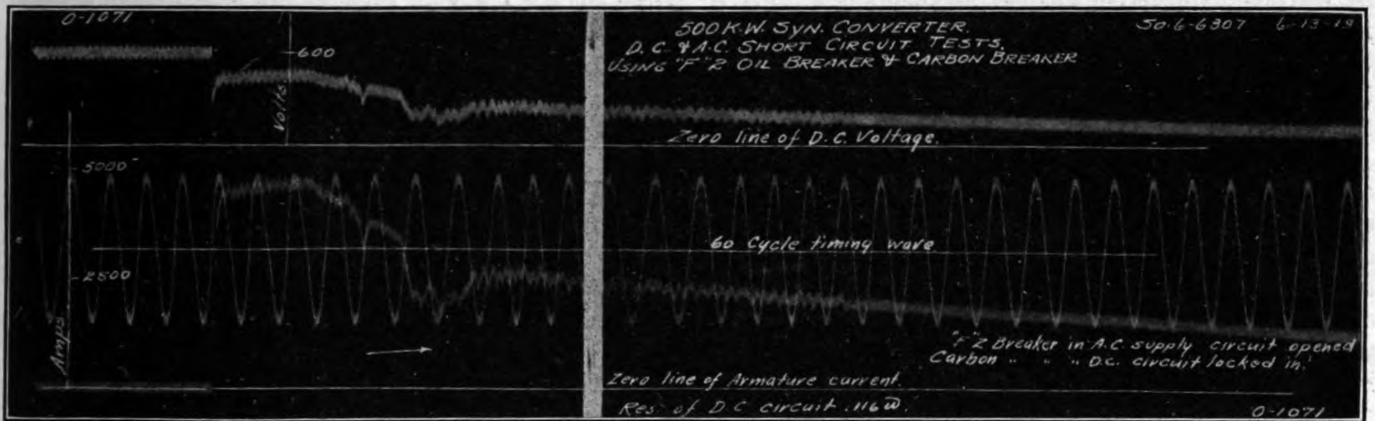

FIG. 9

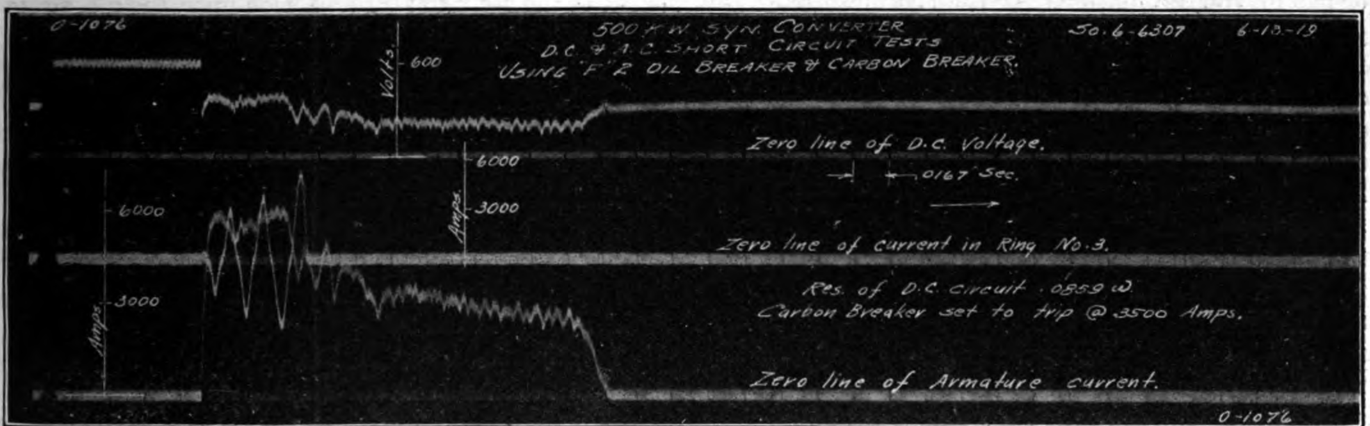

FIG. 10

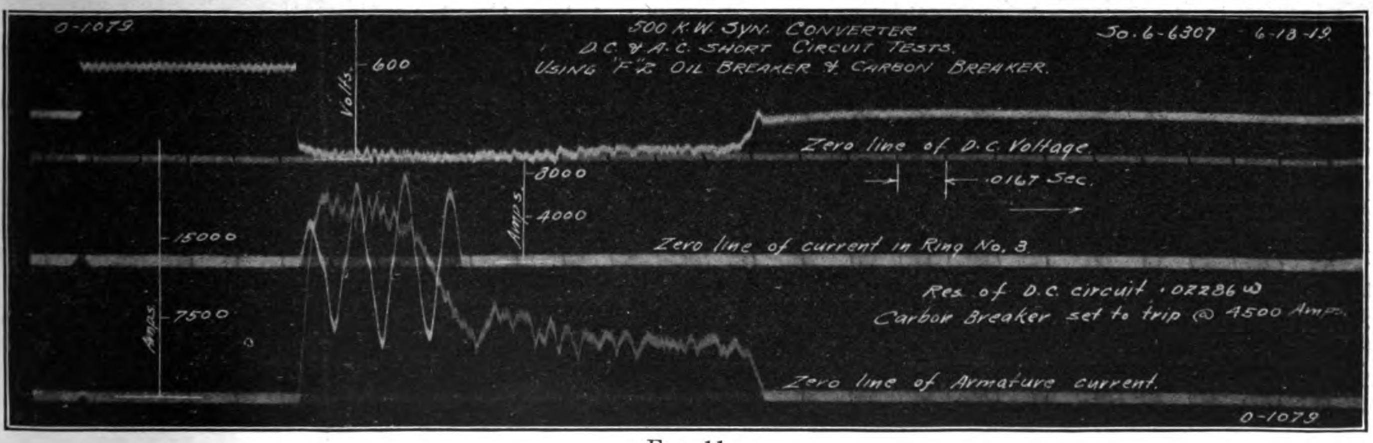

FIG. 11

may be considerable flame on the commutator due to the heavy current, but it does not have the tenacity nor power to cause any serious damage until the voltage is restored. Figs. 1 and 7 covering oscillograms taken in connection with the flash suppressor in which approximately one cycle elapsed between the time of the d-c. short circuit and the application of the a-c. short circuit, show clearly that the machine did not buck over before the a-c. short circuit was applied. During this time the commutator rotated through a distance corresponding to two neutral points. Figs. 8 and 9 show overloads of 3 and 6 times full load respectively when the d-c. breaker was tied in and did not open at all. However, the d-c. supply was tripped off about 0.06 seconds after the instant of short circuit as shown by the slight dip in the current and voltage wave. It is evident from the steady nature of the voltage wave that the machine did not buck over and hang on between arms, although there was considerable flash on the commutator.

Therefore, the ideal circuit breaker is not necessarily one which opens the circuit before the machine bucks over (for it usually does not buck over until the breaker opens) or before the current reaches a certain value, but one which opens the circuit before sufficient gas and volatile matter has been formed over the commutator to cause the machine to buck over when the voltage is restored by the opening of the breaker. It may be said that flashing is roughly a function of the voltage and distance between neutral points and the amount of gas or volatile matter over the commutator. This gas is again dependent upon several other variables, such as, the inherent commutating characteristics of the machine (which is a measure of the local short-circuit currents under the brush), the value of the load current and the time it has been flowing, the grade of brush, etc.

It is the writer's opinion in view of the above tests that a moderately high-speed breaker is no better than an ordinary slow-speed breaker. In the case of a moderately high-speed breaker probably as much gas as possible has been formed over the commutator by the time the breaker opens, *i. e.* after this point the gas is dissipated as fast as it is generated. Then a very slow-speed breaker may be even better than a moderately high-speed breaker due to the fact that the voltage will have time to die down appreciably before the breaker opens, especially, if the a-c. supply is opened in the meantime.

Opening the a-c. breaker is of course undesirable because the machine has to be synchronized again. However, this procedure minimizes the flashing considerably. Figs. 10 and 11 cover an overload of approximately seven times full load and a dead short circuit respectively taken under this condition. As shown by the a-c. wave, the a-c. supply was tripped off approximately 0.05 seconds after the instant of the d-c. short circuit. The opening of the d-c. breaker was purposely delayed as long as possible (by changing spring adjustments) so as to allow time for the current and voltage to die down due to the decreasing speed as well as the dying down of the field flux. In the case of the dead short circuit it may be seen that the current has dropped to almost one-fourth of the maximum short-circuit value and the voltage has dropped to less than one-half normal value when the d-c. breaker opens. The machine immediately clears itself upon the opening of the d-c. breaker as shown by the voltage record. During the period prior to the opening of the d-c. breaker there was of course considerable flame on the commutator but due to the limited voltage on the commutator (with the d-c. breaker closed) the arc did not have the tenacity to hang on, and by the time the d-c. breaker opened the current and voltage had reduced to such an extent that the arc could not establish itself.

Influence of Commutating Characteristics on Flashing

Oscillograms covered by Figs. 12 and 13 which were taken at lighter loads and where the a-c. supply was cut off prior to the opening of the d-c. breakers, show clearly by the dip in the current and voltage wave that the machine bucked over slightly before the d-c. breaker opened, which appears contrary to previous conclusions. However, at this light load the voltage on the commutator is not appreciably reduced. Furthermore, with the a-c. supply cut off, the neutralizing effect of the a-c. armature reaction upon the d-c. armature reaction is absent. Therefore, the converter, operating as a straight d-c. generator with the increased effect of the armature reaction upon the commutating-pole circuit, is erroneously under-compensated, with the result that the sparking under the brush is greatly increased which together with the high voltage between neutral points causes the machine to flash over even with the d-c. breaker closed. This again emphasizes the importance of the inherent commutating characteristics of the machine.

The relative strength of armature and commutating-pole fields has a considerable influence upon the commutation and hence upon the flashing of a synchronous converter on sudden changes of load and extreme overload or short circuit. Under normal load conditions the a-c. m. m. f. opposes the d-c. m. m. f. In the interpolar space the resultant armature reaction is only about 15 per cent of the d-c. armature reaction, and is in the same direction as the d-c. reaction. The commutating-pole field ampere-turns under this condition are just sufficient to buck down this resultant m. m. f. and in addition to force sufficient flux across the commutating-pole gap to generate the required counter voltage for commutation. However, at the instant of short circuit the converter acts largely as a d-c. generator delivering the first rush of current from its own inertia, with the result that the machine is enormously under-

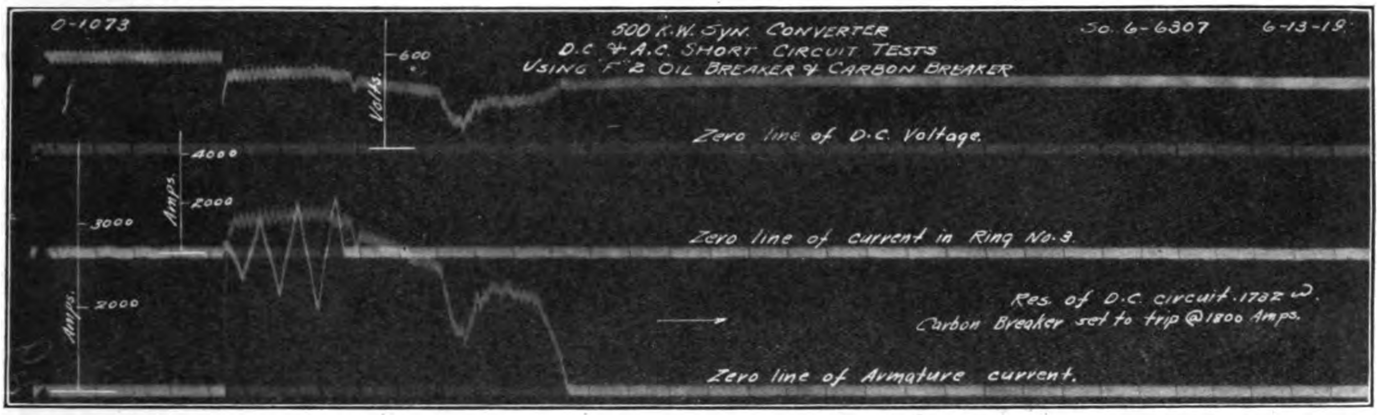

Fig. 12

compensated. In fact, with the relatively low a-c. armature reaction at the instant of short-circuit, the resultant armature ampere-turns may be even greater than the commutating-pole ampere-turns, which means that the commutating-pole flux is actually reversed. This of course depends upon the relative amount of the commutating-pole m. m. f. expended in bucking down the armature m. m. f. and in forcing the flux across the gap. The larger the proportion of the ampere-turns expended in the commutating-pole air gap, or its equivalent, the less will be the effect of the armature reaction upon the commutating-pole flux and hence upon the commutation and flashing of the machine. Furthermore, on extreme overload or short circuit the machine falls back in phase similar to a synchronous motor carrying load with the result that the a-c. armature m. m. f. lags (in space position) with respect to the d-c. armature m. m. f. which is fixed in position by the position of the d-c. brushes. Therefore, even after the first instant of short circuit and after the a-c. m. m. f. has established itself the resultant armature reaction is still proportionately higher than the increase in load due to the relative shift in the position of the a-c. and d-c. armature reaction. This produces a result similar to the conditions in the first instant of short circuit, *i. e.* an under-compensated machine. Trouble from this source can also be minimized by increasing the strength of the commutating-pole field relative to the armature.

Sudden changes in the applied frequency to the converter is equivalent to the machine being out of phase and produces similar results from the standpoint of flashing. In fact, our attention was first called to the importance of the relative strength of the armature and commutating-pole fields by a case of trouble from this source in connection with flashing on a 1000-kw. 600-volt 25-cycle converter at the plant of the Philips Sheet & Tin Plate Co. at Wierton, West Virginia in the early part of 1917. This converter is connected to the secondary of an induction motor which drives a rolling mill and which is subjected to very sudden changes in load. These sudden changes in load produce sudden changes in speed of the induction motor with a resulting sudden change in the frequency applied to the converter which causes flashing in a manner referred to above. A change was made in the commutating-pole circuit to strengthen the commutating-pole field in an effort to eliminate the flashing trouble. This change was to place, approximately, three-quarters of an inch of brass liners at the back of the commutating pole. New commutating-pole windings to supply the additional ampere-turns required as well as new commutating poles to allow space for the brass liners, were also required. These brass liners being of conducting material, also have a tendency to damp out the pulsations of the commutating-pole flux caused by the pulsating armature reaction. This change practically

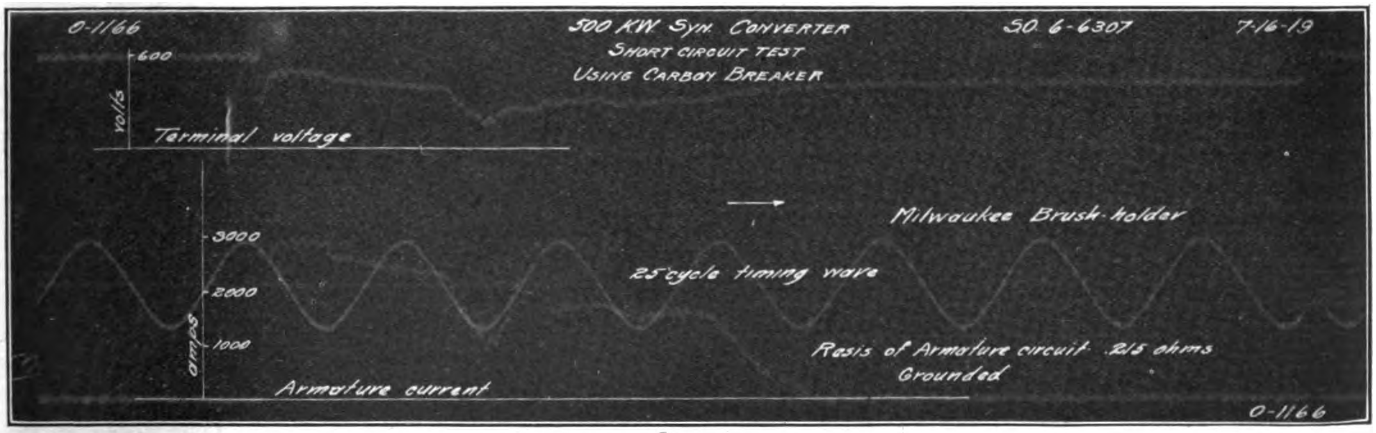

Fig. 13

eliminated the flashing trouble on this machine and showed a field for development along this line.

Quick-Acting Circuit Breaker

Tests made in connection with a modified high-speed railway-type breaker have been previously referred to

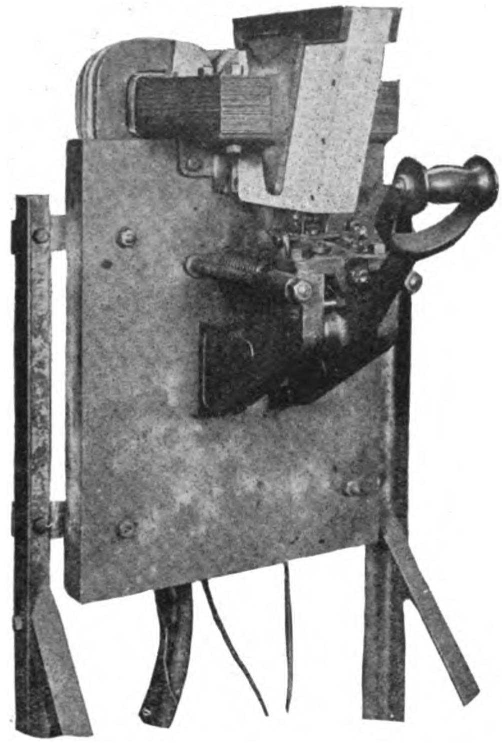

Fig. 14

see Figs. 2 and 3. This breaker has sufficient speed to protect the machine in most cases but is not suitable for this size machine on account of its limited continuous current carrying capacity. Its high speed is due to some extent to its over-rated application in this case.

A 2000-ampere high-speed breaker now being developed and which is still in the experimental stage was also tried out with some success. However, even with this breaker complete protection could not be obtained. Illustrations in Figs. 14 and 15 show front and rear views respectively of this breaker. On dead short circuit this breaker has a speed of, approximately, 0.014 second for complete opening. The arc tips begin to open in approximately 0.004 second. Dead short circuits on the machine when protected by this breaker are shown in Figs. 16 and 17. In these cases the rate of initial increase in current is limited to approximately 2,100,000 amperes per second, about 65 per cent of the normal rate of increase. This reduction in rate of current increase is such that the speed of the breaker is sufficient actually to limit the maximum value of the short-circuited current. This lower rate of increase in the direct current is due to a 0.15-millihenry reactor which was put in the circuit. The primary purpose of the reactor is to shunt the trip coil of the breaker so as to give a greater rush of current through the trip coil and thereby increase the speed of operation of the breaker. Although this reactor was effective in increasing the speed of the breaker as well as limiting the rate of increase in the direct current, a very undesirable and vicious voltage was induced in the coil upon the opening of the d-c. breaker, which in some cases appeared to re-establish the arc across the breaker.

This breaker was about as much underrated as the modified railway breaker was overrated on this application and it is believed that it would have a slightly higher speed on higher currents than dealt with in this case. A smaller breaker with lighter moving parts is now being considered on which it is expected to obtain higher operating speed.

Some very interesting high-speed photographs of the machine when flashing and when protected by this breaker are reproduced in Figs. 18 and 19. The camera used in taking these photographs has twenty-two stationary lenses with a rapidly revolving shutter in the rear which opens them in rapid succession. The time interval between each exposure is of course dependent upon the speed of this shutter which is variable. The progression of the phenomena is in the

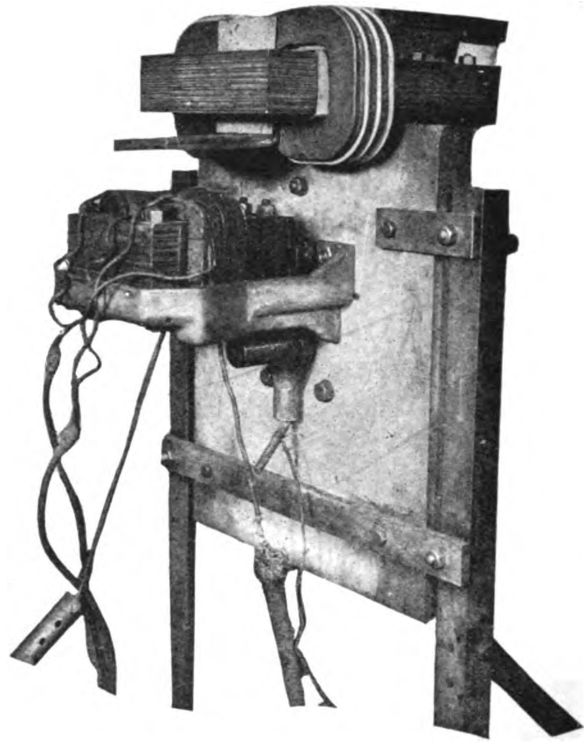

Fig. 15

order of the numerals on the plate. The pictures marked with the sub letter S were taken at the same instant (by two different lenses) as the picture marked with the corresponding number without the sub letter S. When properly mounted these pairs of pictures can be viewed to a great advantage through a steroscope which brings out the third dimension or depth of the picture.[1]

1. A detailed explanation of the construction and operation of this camera is given in an article by Mr. J. W. Legg in the December 1919 issue of the *Electric Journal.*

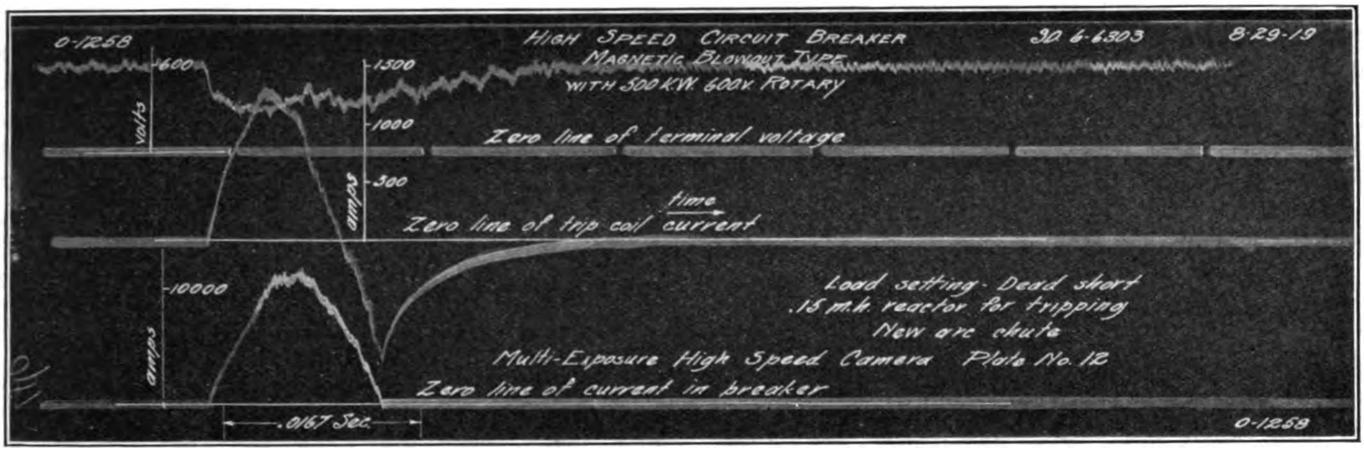

FIG. 16

Fig. 18 which corresponds to oscillogram in Fig. 16 shows a picture of both the machine and breaker when flashing. There is approximately 0.0018 second interval between each picture. Pictures 1 and 17 which show the beginning and the end of the phenomena shown on this plate overlap and are shown together. The small light spot in the lower left hand corner of picture 1 shows the beginning of the arcing. The breaker is not yet visible. In picture 2 the arcing on the machine is increasing the several spots of light representing sparking under the several brush arms, and the beginning of the breaker opening is shown in the upper right-hand side of the picture. In picture 3 the flashing is still progressing, and so on to picture 7 where the breaker has completely opened and the machine flashed over. The machine continues to flash throughout the length of this series of pictures. Fig. 19 which corresponds to oscillogram Fig. 17 shows a closer view of the flashing on the machine alone.

Flash Suppressor

The flash suppressor as applied to converters is simply a high-speed switch actuated by the short-circuit current, much in the same manner as a circuit breaker, which short-circuits either all or a part of the collector rings (usually three or six in the case of a six-phase machine.) This reduces or kills the voltage on the commutator to such an extent that it prevents the machine from flashing over. A detailed explanation of the flash suppressor is given in an article on this subject by Mr. F. T. Hague and Mr. N. W. Storer in the May 1918 issue of the *Electric Journal*; and its particular application to the generators of the Chicago, Milwaukee and St. Paul motor-generator sets is given in an article by Mr. Daivd Hall in the January 1920 issue of the *Electric Journal.*

The operation of the flash suppressor means practically a short circuit on the a-c. system through the converter transformers. The alternating current drawn on a dead d-c. short circuit where the high reactance transformers are used for compounding purposes, was only 15 to 20 per cent higher with the suppressor in operation than without. Thus on dead d-c. short circuit the suppressor did not add so much to the duty of the machine and a-c. system. However, each overload on the d-c. side above a predetermined value for the suppressor to operate meant a short circuit on the a-c. side. Another undesirable feature was the fact that the machine fell out of step and had to be synchronized again. In an effort to limit the heavy alternating current drawn by use of the flash suppressor and so eliminate this objection, tests were made with

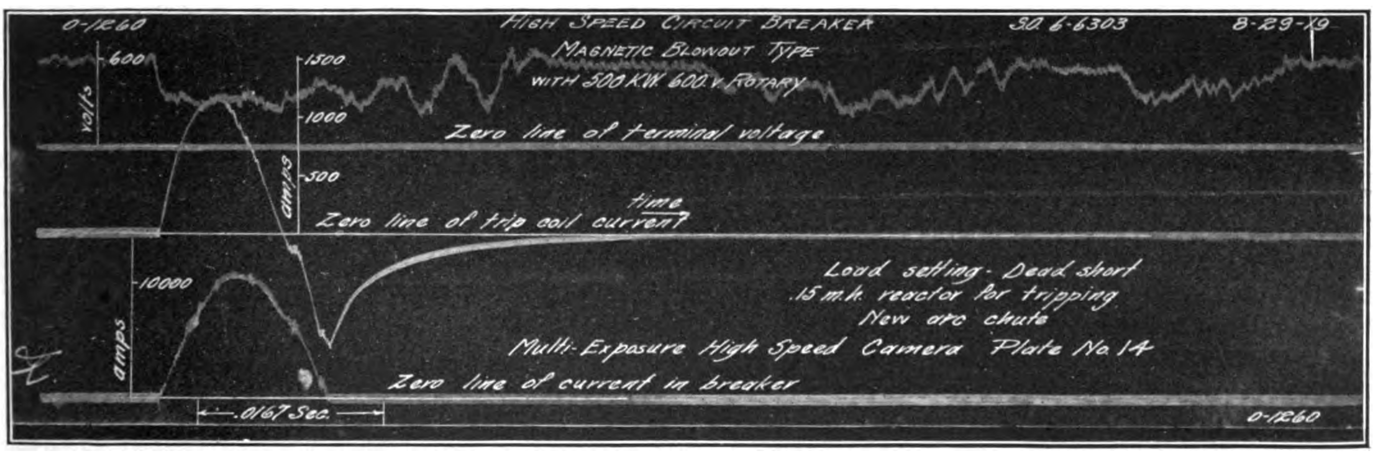

FIG. 17

inductance in the local suppressor circuit for the purpose of finding out the maximum value of inductance which could be used to limit the alternating current and still reduce the d-c. voltage sufficiently to give protection on the d-c. side. For each setting of inductance the d-c. short-circuit load was increased to the point of prohibitive flashing. It was found that in order to give protection the value of this inductance had to be such that upon the opening of the d-c. breaker the d-c. circuit breaker was put in the local leads of the suppressor circuit in connection with the above tests, so as to open the suppressor circuit and throw the machine back on the line. The trip circuit for the oil breaker was energized immediately after the opening of the d-c. breaker by means of an auxiliary contact on this breaker. Figs. 20 and 21 show tests in which the flash suppressor circuit was opened and the machine thrown back on the line. It was found that the sup-

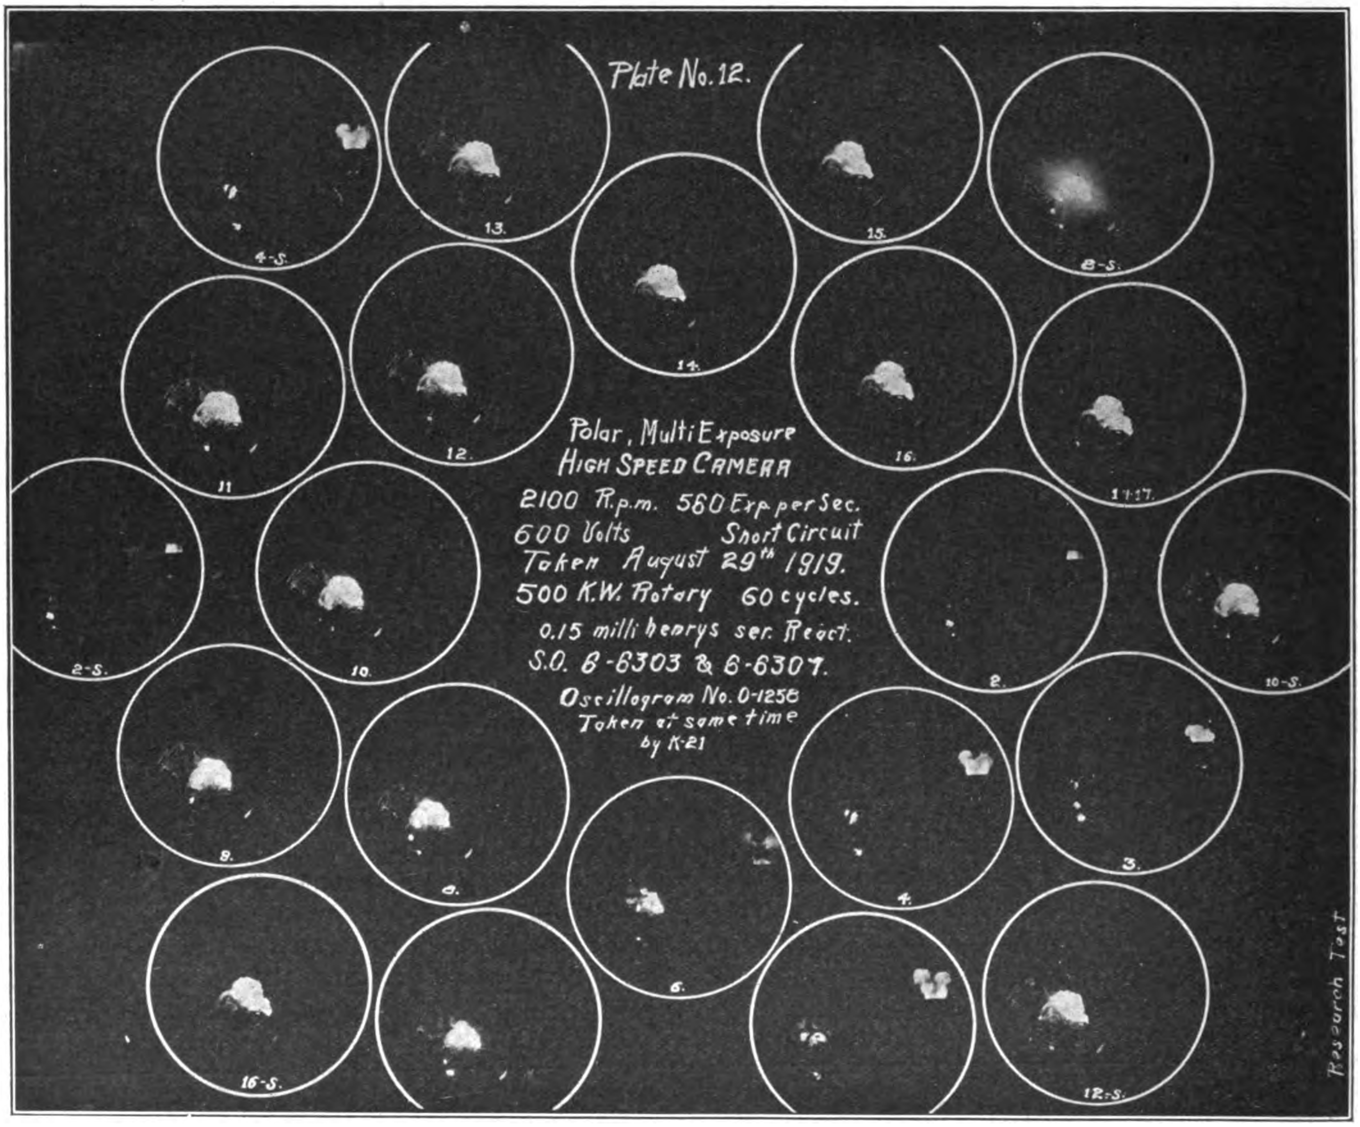

Fig. 18

voltage would not rise above the value it had dropped to due to the d-c. short circuit, *i. e.* there must be no appreciable rise in voltage when the d-c. breaker opens. Also the tests showed that reasonable protection could be had at about eight times full d-c. load without drawing over nine times full load alternating current, or at about 12 times full direct current without drawing over 10 to 12 times full load alternating current.

With the idea of eliminating the undesirable feature of having to re-synchronize the machine after the operation of the flash suppressor, a three-pole oil pressor circuit could be opened and the machine thrown back on the line in this manner without any particular disturbance up to the point where the induction in the suppressor circuit must be decreased (for protection to the d-c. side) sufficiently to cause the machine to fall out of step. This point is at approximately ten times full load. Some evidence of the tendency of the machine to fall out of step is shown by the slight oscillation in the d-c. voltage wave in Fig. 21. The oscillogram in Fig. 22 shows a short circuit of approximately 13 times load and the pulsations in the d-c. voltage wave show

clearly that this machine is out of step. The frequency of these pulsations corresponds to the slip frequency on the commutator and shows the extent to which the machine is out of step. When the suppressor circuit is opened and the machine thrown back on the line, when it is out of step, it flashes over due to phase displacement on the a-c. side regardless of the value of the d-c. load.

All of the above tests show clearly that the flash suppressor will give ample protection from flashing to the converter as far as the a-c. side is concerned. However, there are several problems connected with the application of the flash suppressor to synchronous converters, such as, the increased duty on the collector ring, disturbance to the a-c. supply systems and the machine's falling out of step, which have not yet been worked out.

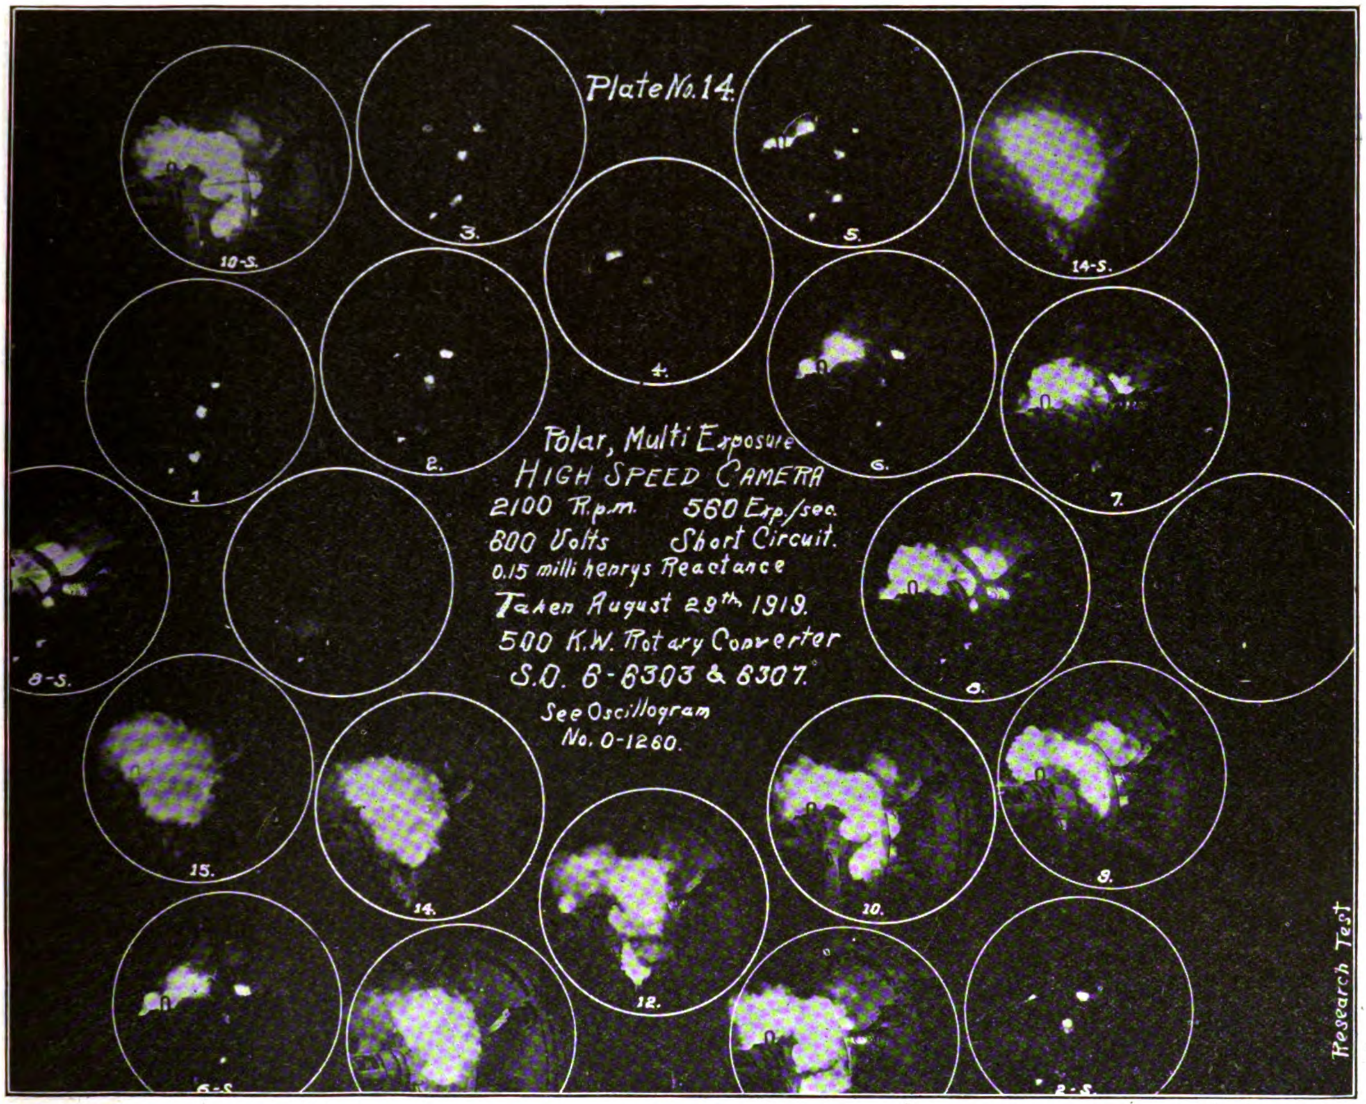

FIG. 19

Flash Guards or Barriers

Various forms of flash guards have so far proved to be unsuccessful. The general construction of these guards consisted of two continuous end rings, one at the back of commutator next to commutator necks and one at the front of commutator, with barriers between arms extending down to within approximately 1/32 in. of the commutator. These guards were made of asbestos lumber, a composition of asbestos and asphalt. Considerable trouble was experienced at first from the arc going under the front guard ring to the commutator *V* ring. This was remedied by making this front ring counterbored so that it extended over the face of the commutator a small distance as well as below the front end of the commutator. However, even this did not prevent the machine from flashing; with the arcing space confined by these guards the arc seems to become explosive and force itself to parts that it otherwise has no tendency to go. Furthermore, after several flashes the surfaces of these guards become so carbonized and covered with metal particles that they actually aggravate the flashing rather than prevent it. In fact, in several instances the guards were so carbonized and metal-smeared after the flash-over, that streamers would

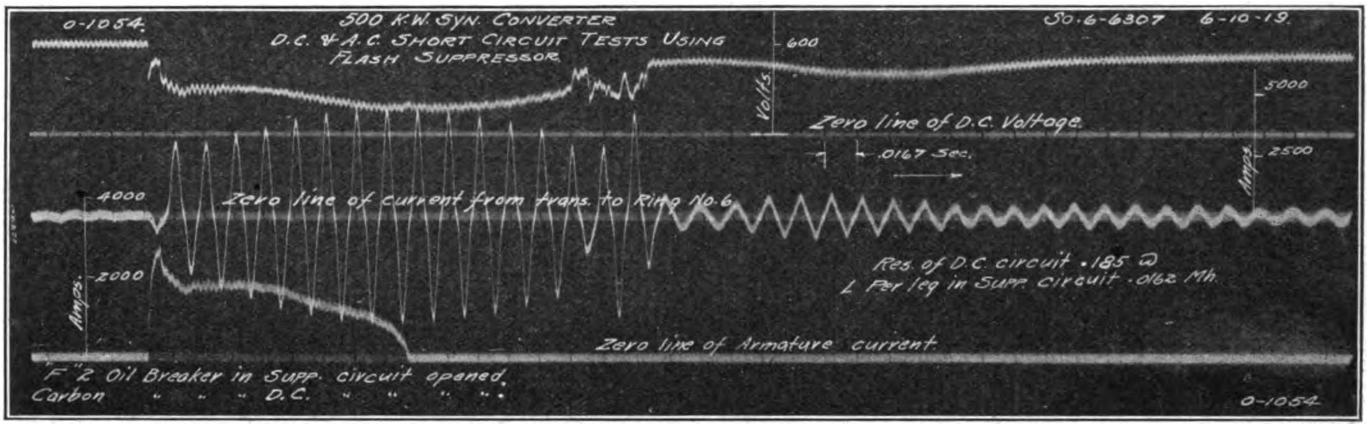

FIG. 20

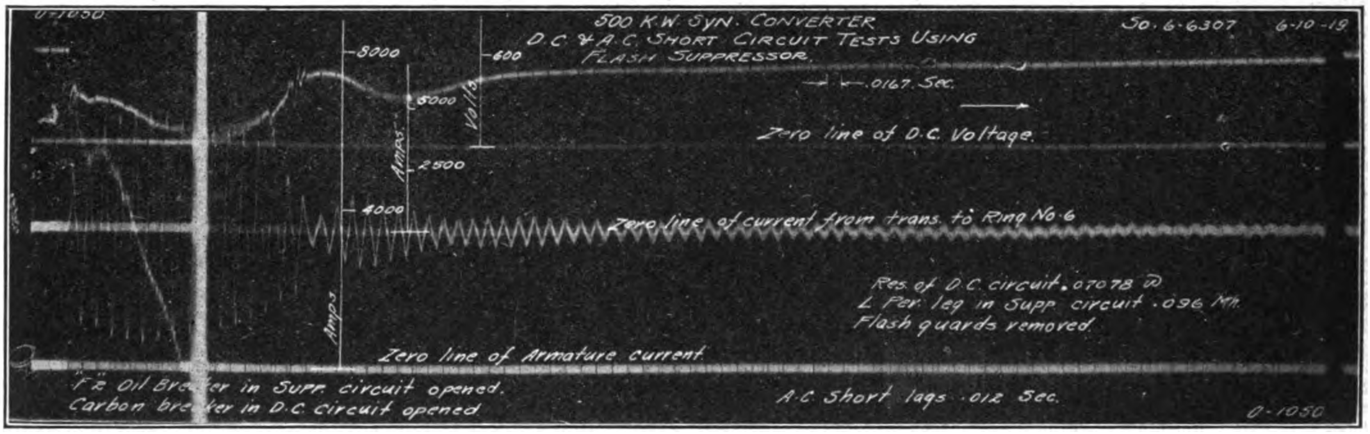

FIG. 21

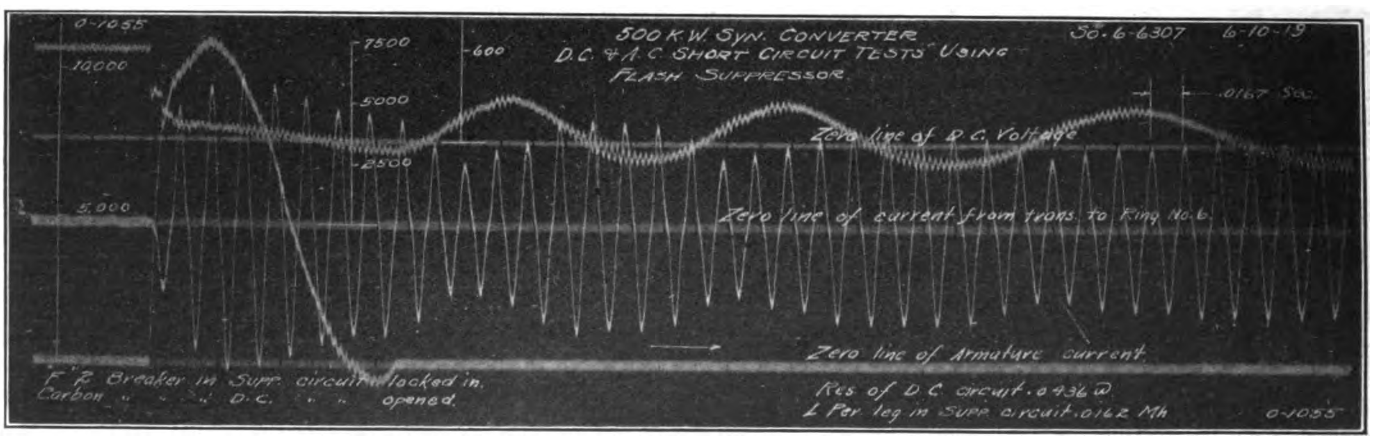

FIG. 22

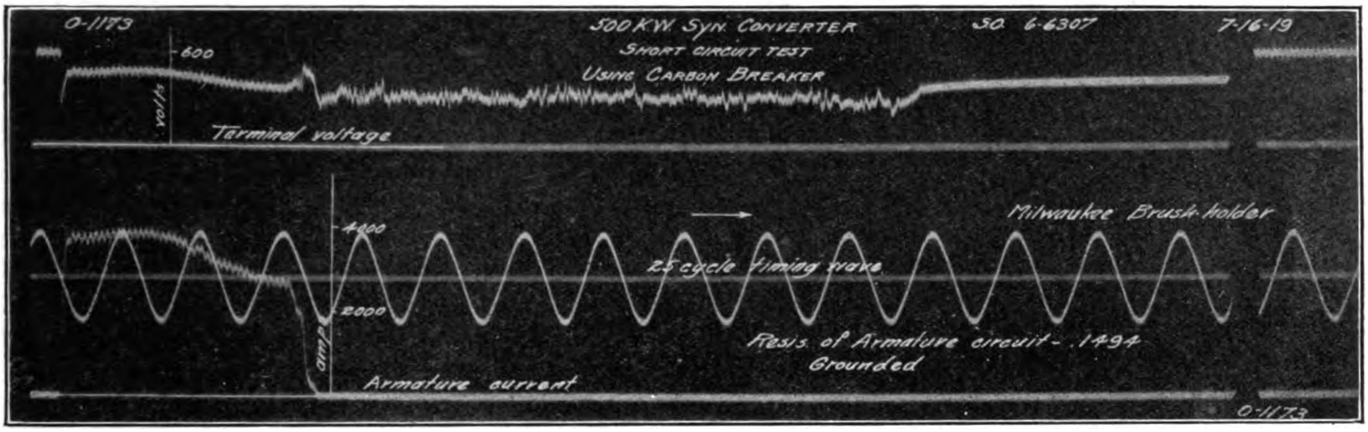

Fig. 23

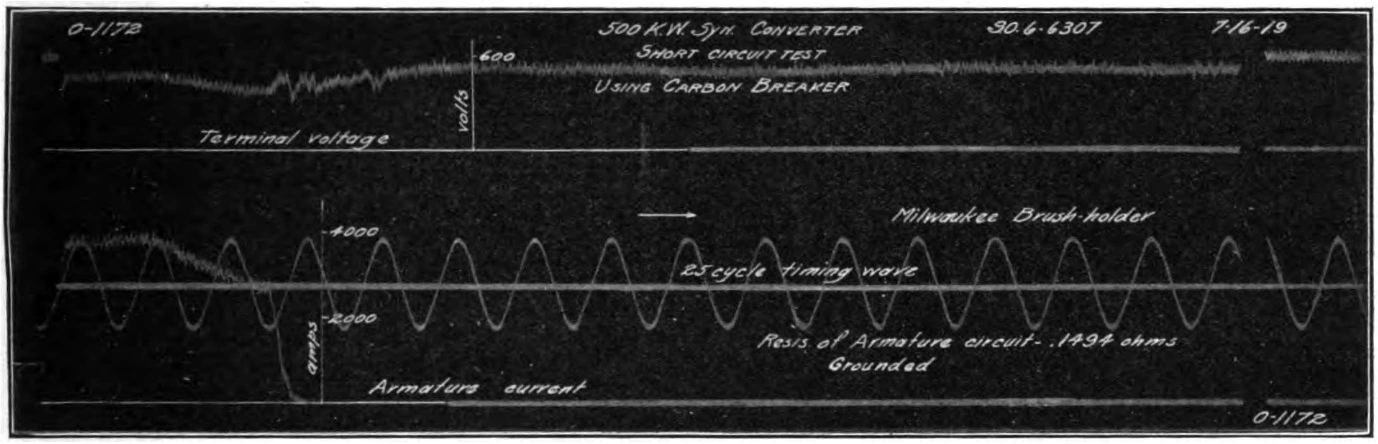

Fig. 24

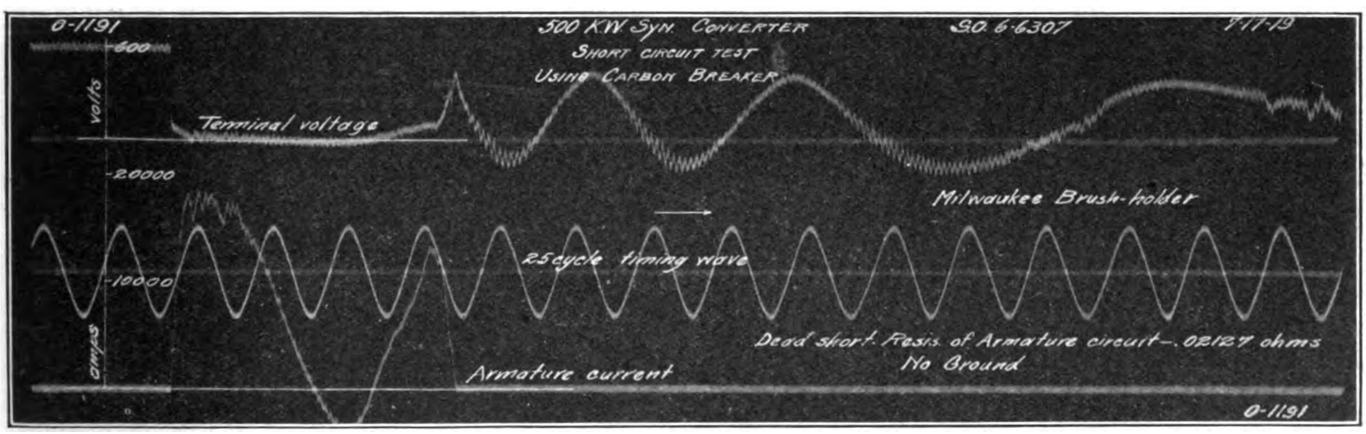

Fig. 25

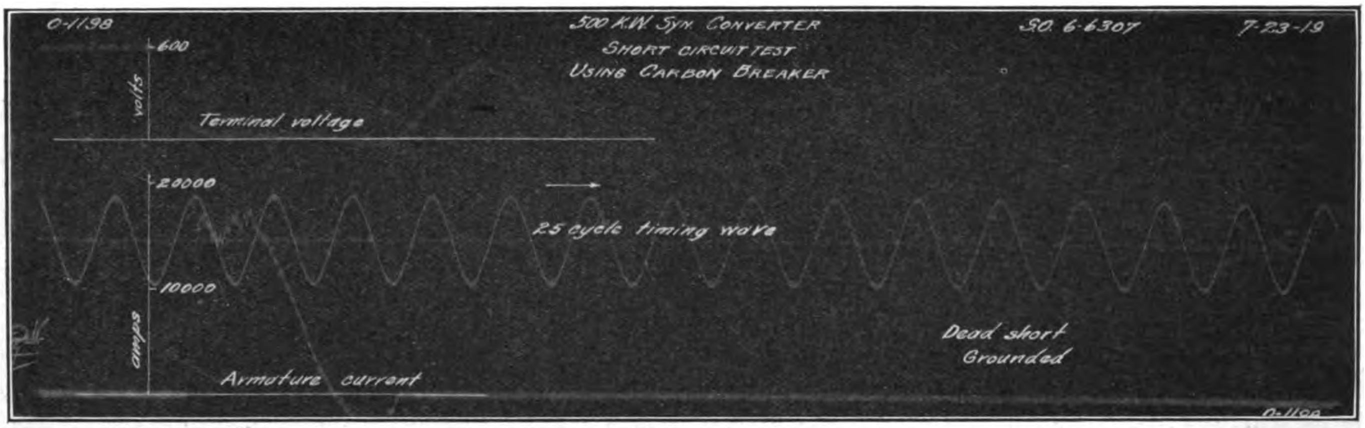

- FIG. 26

run along the surface at no load and normal voltage. All tests indicated that these barriers should be of an open construction and as far away from the source of the arc as possible so as to give it sufficient room to expand and dissipate itself without becoming explosive. In other words the barriers should be next to the parts to be protected (as the pedestal and leading side of brush holders) and as far away from the arc as possible. This fact is borne out by oscillogram in Fig. 23. In oscillogram shown by Fig. 24 the machine flashed over to the front pedestal (no flash guards on machine). In an effort to keep the arc from jumping to the pedestal, the front ring, which had been slightly carbonized on a previous flash-over was then bolted back on front of the brush-holder brackets and the short circuit repeated as shown by Fig. 23. This time the arc jumped along the surface of the front ring between the two front brush holders on the two lower arms and practically demolished these two brush holders. Later this ring was fastened to the pedestal, away from the commutator and the source of the arc, and gave complete protection clear down to dead short circuit except for slight pitting of the brush holders.

This shows very clearly that the flash guards increase the tendency of the machine to flash over after they have become carbonized. No suitable material for this purpose which will not carbonize has been found so far. Best results have been obtained by protecting the pedestal with an arc shield and leaving as much space as possible on the commutator for the arc to expand. This also gives free access to the commutator, the back of which is one great disadvantage and objection to any form of flash guard. This same protection can be offered more readily and easily by insulating both pedestals much in the same manner as for the elimination of bearing currents. This, however, has the disadvantage that a dangerous voltage may exist between the pedestals and ground in case the armature becomes grounded. With the pedestals insulated this machine can be dead short-circuited with the ordinary carbon breaker with no particular damage to the machine except a slight pitting and marking of the brush holders. Figs. 25 and 26 show dead short circuits with the machine grounded and ungrounded under the above condition. Evidence is again shown of the machine falling out of step as discussed under the heading of flash suppressors. The fact that the d-c. voltage is pulsating undoubtedly prevents the arc from hanging on. It goes out when the d-c. wave passes through zero. For this reason a dead short circuit on a converter in connection with a slow-speed breaker does not appear to be as vicious or tenacious as a short circuit at a point just before the machine falls out of step and the d-c. voltage is maintained in one direction. This point is about 10 to 12 times load in the case of this machine. This is also about the point of maximum $E\,I$ output.

PRODUCTION OF ELECTRIC POWER AND CONSUMPTION OF FUEL

The Geological Survey has published a compilation of its data showing kilowatt-hours produced in each state by water-power as compared with the power produced by fuel. This report covers a four month period from February to July, inclusive, 1919. This table also shows totals of power so produced with the average daily output in kilowatt-hours and the percentage of waterpower output.

The figures showing the production of electric power by fuel in each state are divided so that they show the coal, oil and gas used in producing the power.

The report is based on the returns received from nearly 3000 electric power plants engaged in public service, including central stations, electric railways and other plants. Returns were received from plants whose aggregate capacity of generators is about 90% of the total installed capacity of generators of public utility plants. Estimates of the output of plants which did not submit returns were made from available information. The Geological Survey intends to issue supplements to this report as the data is secured.

Automatic Substations for Heavy City Service

BY R. J. WENSLEY

Westinghouse Electric & Manufacturing Co.

WHEN automatically controlled substation equipment was in the development stage, the general consensus of opinion was that its greatest field lay in relieving the smaller interurban systems of a greater portion of their substation operating labor. While many such systems have installed one or more automatic substations, they have not displayed the interest in the matter that was expected. In many cases the officials have professed their total inability to finance the new apparatus even though the investment would show a very attractive saving.

On the other hand, it is very gratifying to those directly interested in the subject, that the larger city street railway systems are eagerly taking up the question of rebuilding their distribution systems by taking full advantage of the decided savings made possible by automatic operation of the converting equipment. Orders received from this source have more than made up for the failure of the smaller roads to equal expectations.

The earlier street railway systems made little or no attempt to lay out a distribution system with economy or efficiency. Any location available was seized on as a power house site. Cables were run the shortest possible distance to the trolley and from that point the trolley was usually the only means of carrying the current. As service demands increased due to larger cars and closer schedules, the voltage drop became too great for satisfactory service even by the rather lax standards of those days. To remedy this the trolley voltage was gradually increased from the early standard of 500 volts to 550 and then to 600 volts and the feeders were run parallel to the trolley so as to help the voltage at the ends of the lines.

As the traffic demands increased another factor entered into the distribution problem, that of electrolytic destruction of underground metallic structures such as water pipes, gas mains and so forth. This necessitated heavy copper feeders in parallel with the rail to prevent the returning current from seeking to travel over the underground piping system. The negative booster was also freely used to compensate for the drop in these return feeders. This of course was practically pure waste so far as efficient utilization of the power was concerned since the entire output of the boosters was expended in heating the cables. It was however a good preventive of electrolytic troubles and therefore widely used in spite of its wastefulness.

All this time the source of power supply was almost invariably a slow-speed d-c. machine operating at 550 to 600 volts, and direct-connected to a reciprocating engine.

Presented at the Pittsburgh Meeting of the A. I. E. E., March 12, 1920.

These units grew to unwieldy size in the attempt to keep up with the ever increasing demands of the public for more transportation facilities. The engine driven alternator and then the turbo alternator came to the front as the most economical method of power generation and the railway substation followed soon after. There were of course, railway substations in operation long before the turbine became popular but these were exceptions to the rule.

Some of the larger cities soon installed a distribution system composed of one or more central steam plants with a number of large substations located in various parts of the city. Owing to the cost of operating labor these were kept down to the least possible number even at the expense of considerable investment in feeder copper. There are many of the old systems still in operation with an unwieldy amount of feeder copper in the air and with I^2R losses amounting into the millions of kilowatt hours per year. Poor trolley voltage with consequent slowness of schedule speeds is a natural result of this. The possible savings to be had from reduced copper losses, reduction in running time and decreased amount of motor repairs by rebuilding the distribution system would in many cases enable a property to make a better showing of earnings than it is making at the present time.

The development of automatically controlled substation equipment has now placed in the hands of the distribution engineer a possible method of reconstruction that is little short of ideal. Substations can now be scattered about without the specter of heavy and ever rising operating labor expense to be watched. The increase in the number of substations enables the holding of good trolley voltage without the heavy expense in large feeder capacity as has previously been the case. Trouble due to electrolysis is greatly minimized and in many cases entirely eliminated by the increase in number of substations.

These substations are of course not one hundred per cent efficient so care must be used in applying this remedy that it not be overdone. Sizes of machines and stations must be carefully calculated so that the load factor will be as high as possible. In deciding on the best sizes of equipment to install, several factors must be considered. Interchangeability is always desirable and therefore there should be as few different sizes of machines as consistent with economical operation. Wherever possible the machines in any one station should be of the same size so that their places in the operating schedules may be interchanged. In most city applications two machines will prove to be the most desirable number for an automatic station with space provided for a third machine to take care

of future growth. In most cases this problem of added capacity can be better solved by the installation of additional substations when the load grows too great for the original installation of converting equipment. This latter method keeps down the feeder copper requirements.

Where two machines are selected for a given location each one must be capable of carrying the normal off peak load without assistance. The combined capacity must be sufficient to take care of the peak load. In some cases this will result in more capacity than necessary during the off peak period, and in other cases just the reverse, depending on the off peak load being less or greater than half the peak.

By selecting machines of combined continuous capacity equal to the r. m. s. value of the peak load, a reasonable reserve capacity is allowed since the two-hour rating will probably allow one machine to pull over the peak if the other is out of service. To help in such cases, a limited number of feeders should be run through from one station to another so that the feeder may be opened in the station in trouble thus transferring a portion of its load to an adjacent station. The automatic load limiting resistances supplied as part of a railway automatic substation will also help out in such cases at the expense of the trolley voltage.

To illustrate the way in which the problem of applying automatic substations to city service should be approached, a city of about 300,000 population has been selected to serve as an example. This city is now served by an excellent example of the old method of centralized distribution. Fig. 1 shows in a general way the stupendous amount of feeder copper that has been installed in the attempt to give good service. The two plants are about three-quarters of a mile apart on the same side of the city and about one mile from the loop district where lies the greatest load concentration.

The heaviest loaded lines are on the opposite side of the city from the power plants. The lower plant is the oldest one and is mainly equipped with reciprocating units. The total d-c. capacity of this plant is about 8000 kw. The upper plant is a modern turbine station which supplies power for several interurban systems. In this plant are located three 2000 kw. of synchronous converters. This gives a total d-c. capacity of about 14,000 kw.

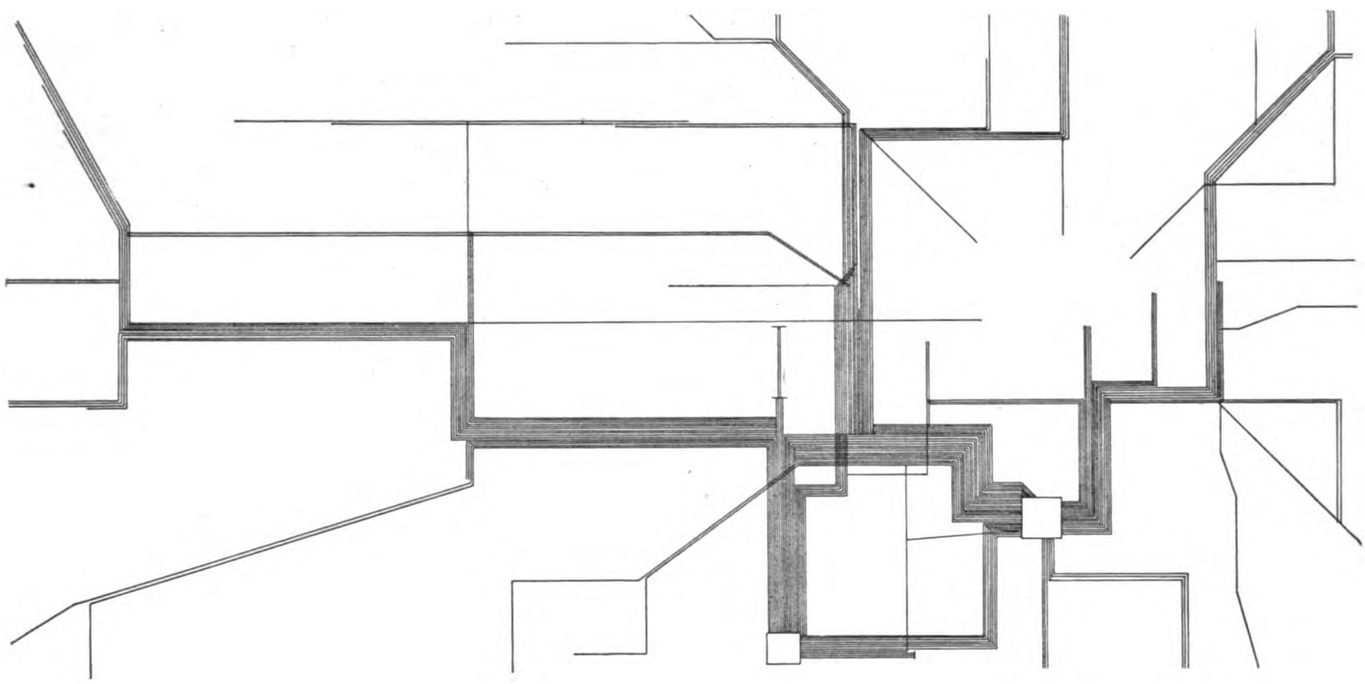

Fig. 1

Most of the feeders shown in the cut are 1,000,000 cir. mils. There is a total of 25,800,000 cir. mils in feeders both positive and negative leaving the old plant, 23,000,000 cir. mils leaving the new plant and 8,000,000 cir. mils in tie lines between the plants. One of the heaviest loaded lines runs from the loop directly away from the plants with the end of the line about seven miles distant measured along the feeder run.

Of this total feeder capacity about 40,000,000 cir. mils are in the positive feeders, the remaining being in the return feeders. The average length of feeder to the center of its load is about two miles. The peak load on the two plants is about 22,000 amperes. Assuming for estimating purposes that the rail and return feeder drop will be somewhere near equal, we find that at peak load the average voltage at the load centers will be 475 volts with 600 volts on the station

bus bars. The I^2R losses reach the enormous value of 2750 kw. or 20 per cent of the total d-c. input, over the peak period. The average trolley voltage at the car will be somewhat less than that given for the load centers. In many cases the voltage on the car is so low that it is almost impossible to read news print during the evening rush hour.

This city operates about 300 cars during the periods of heavy traffic most of which are double truck, 20 tons in weight with two 60-h.p. motors geared for 27 miles per hour. The schedule speed is about six miles per hour during the evening rush hour and even this can hardly be held. Due to the low average voltage the cars cannot accelerate rapidly as they should and bunching soon occurs which only aggravates the trouble.

The problem is to lay out a new distribution system which will reduce the transmission losses to a minimum, raise the average trolley voltage to a reasonable value, keep the stray earth currents to a minimum, and at the same time avoid raising the expense for operating labor to an undue amount. All this must be accomplished at the lowest possible net cost.

As a preliminary to deciding on the size and location of substation equipments a spot map of the system should be prepared based on the rush hour schedules. A sample of this is shown in Fig. 2. A factor which upsets the spot map as shown is the fact that there are fourteen interurban lines entering this city all of which operate fairly heavy cars; 45 tons weight with four 90-h.p. motors geared for sixty miles per hour would represent the average. In laying out the power supply it has been asseumd that two of these cars are at the center of each line which they use for entering the city.

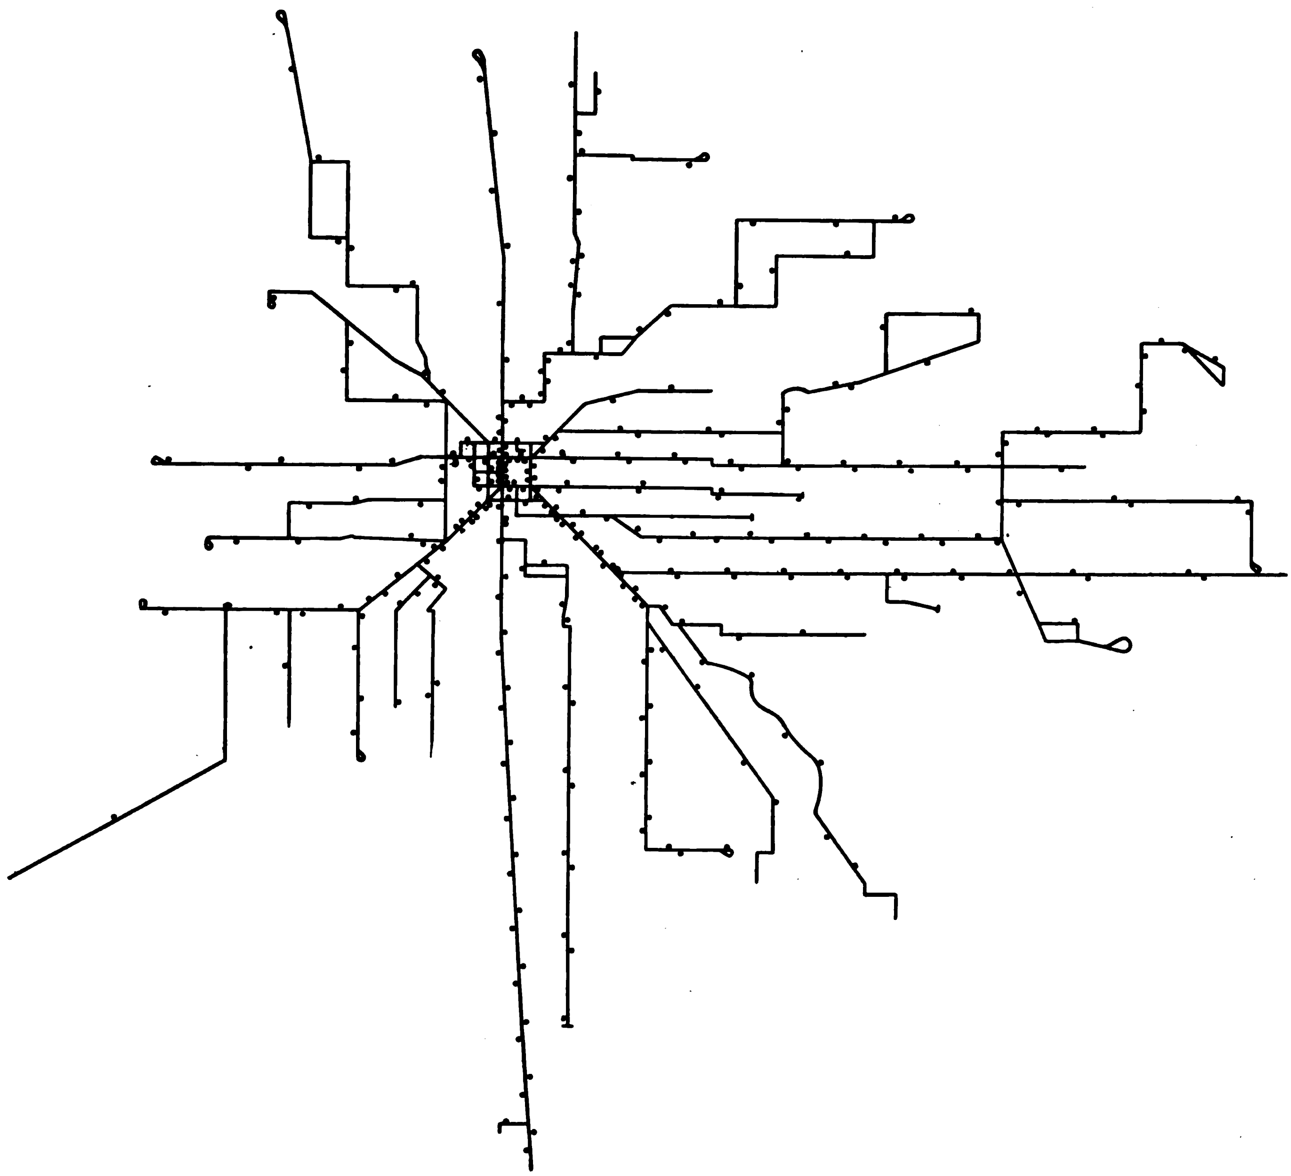

Fig. 2—Spot Map—Automatic Substations

Certain other conditions such as heavy seasonal loads must be considered. There are in this city three parks that are heavily patronized and a fair ground that is a very heavy peak for one week in the year. Such considerations as these have been used

to modify the strictly mathematical method of locating the new substations. This method is the one described in Richey's handbook as having been used to lay out the feeder system in Chicago, and consists of assuming that the distributed load on each line is concentrated at the center, then, treating the loads as actual weights, find the center of gravity. This locates the substation in the ideal position to feed its section. This ideal location is of course seldom practical and due consideration must be had for local conditions.

In figuring the spot map shown in Fig. 2 the average current per car has been taken as 53 amperes. The interurban cars have been figured as equal to two city cars. The city has been arbitrarily divided into nine districts for the purpose of apportioning the substation capacity. Care was taken in making this division to keep each section down to less than 2000 kw. in possible load as this seemed to be the largest size station that would be advisable on this size of system, having due regard for investment in feeder copper. The center of gravity was then found for each section and the substation located as near this point as a study of local conditions would warrant.

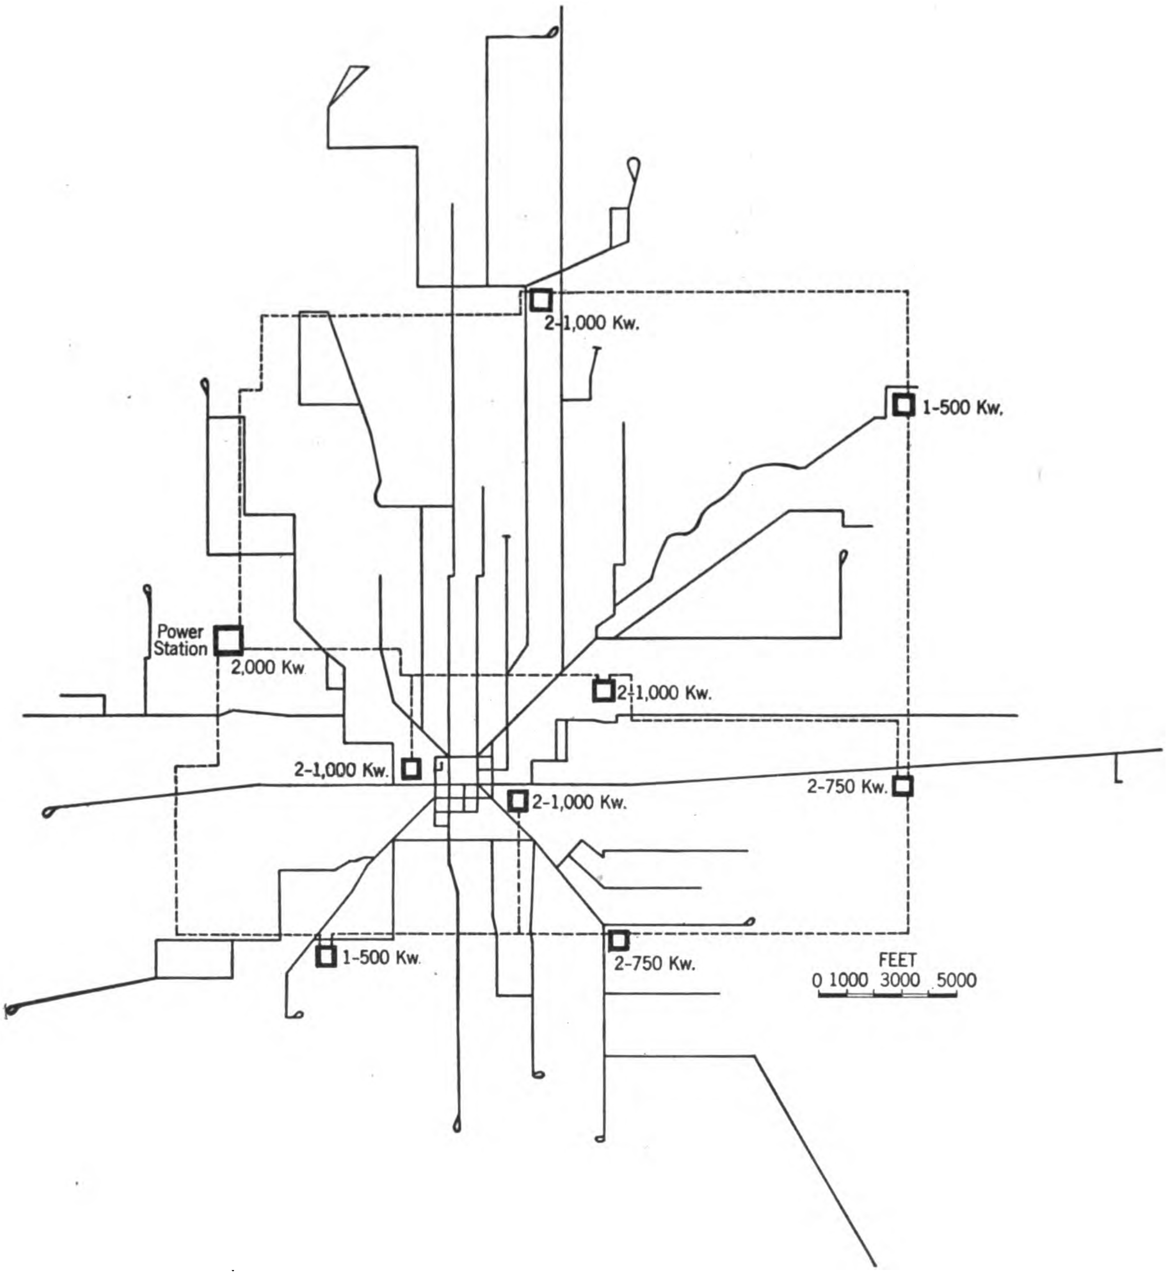

Fig. 3—Proposed Substation Layout—Automatic Substations

The two substations feeding the congested portion of the city were located on each side of the loop district just far enough away to be on the edge of the underground district. This is desirable from the standpoint of economy in installation, although the most desirable location from a standpoint of copper loss and feeder

copper would be right in the center of the loop. This would however result in excessive investment charges for real estate and underground construction. Locations east and west of the center were chosen rather than north and south because of real estate values.

The final location decided for these substations is shown in Fig. 3. The high-tension line locations were picked out by the superintendent of distribution of the street railway company with a view to using as much of the present pole line as possible and of selecting streets for the necessary new lines where there would be the least opposition from the residents and the city authorities. The feeders form a ring bus around the city with a tie line across the center.

The intention is to sectionalize the feeder in each substation and equip the section breakers with reverse-power relays so that any section will be cut out in case of trouble, thus leaving the entire system in operation with the exception of the damaged portion of the line. Owing to the local situation with regard to the telephone companies and the city authorities the maximum voltage which it would be advisable to use above ground is 6600. While this is not the most economical voltage for the amount of power and the distance, it has been adopted because of the great expense of underground high tension feeders at 11,000 or 13,200 volts.

At this voltage the feeder belt may be of 4/0 wire, and the cross tie line of 350,000-cir. mil cable which will give approximately 5 per cent power loss in the a-c. system at full load.

The substations as laid out have the following capacity machines installed: Three with two 1000-kw. converters each; Three with two 750-kw. converters each; Two with one 500-kw. converter each; One of the existing 2000-kw. machines to be retained at one of the steam plants. Total converting capacity installed 13,500 kw. Total peak load at present time 13,200 kw.

While this is apparently only sufficient nominal continuous capacity for the peak, it must be remembered that 20 per cent of this peak is lost with the present feeder arrangement so that if the feeder losses can be reduced to 5 per cent this will leave an actual surplus capacity of 15 per cent. This taken with the two-hour overload rating of the converters will give ample margin of reserve capacity.

The feeder calculations are based on maintaining an average voltage of 550 at the car during the evening rush hours. This property now has the equivalent of approximately 110 miles of 1,000,000-cir. mil copper in the distribution system. With the new substation locations we find that the rail resistance is within allowable limits in nearly all parts of the system. In only a few places will negative feeders be required and these will be quite short. With the widely distributed sources of d-c. energy, the carrying capacity of the trolley wires themselves become an important factor, in the distribution of the 600-volt current.

Of the present feeder system it will be possible to remove approximately seventy miles of 1,000,000-cir. mil cable or its equivalent. At 18 cents per pound this will amount to $205,380 which is the first important item of credit for the new installation.

The old d-c. plant should be scrapped entirely and the proceeds applied on the new equipment. It is estimated that the second hand and scrap value of this plant will be at least $100,000.

The I^2R losses on this system were calculated last year and the value of the current lost in the feeder system only, not including local track and trolley losses, was figured as being $100,000. These figures are not vouched for by the writer but as can be readily imagined from the description of the feeder system, this amount does not seem unreasonable. Since approximately one third of the feeder copper is to be left in service we will assume that the copper losses in the remaining feeders will be in proportion to the amount now in service. This will give us a saving in copper losses amounting to $66,000 annually.

If the rush hour schedules of each car are so speeded up as to save five minutes on the rush hour trip morning and evening, with 300 cars and with platform labor at 40 cents the annual possible saving will be $14,600.

The automatic substation buildings should be of the most simple type of construction possible with no heating apparatus and with no accommodations for operators. If extensive repair work becomes necessary in the winter time a portable electric heater can be installed. By constructing this type of building absolutely without ornamentation, the cost should not exceed $40 per kw. complete. Twenty-five miles of a-c. line will be required which can be partly installed on existing poles. The cost of this should not exceed $5000 per mile.

Gross cost of the new system;

11,500 kw. of substations at $40	$460,000
25 miles of line at $5,000	125,000
Reconstruction of feeder system	25,000
Power house equipment, transformers, etc	100,000
Total cost of automatic substations	$710,000
Credit power plant scrap	100,000
Credit copper removed	205,380
Net cost of automatic substations	$404,620
Fixed charges at 15 per cent	$75,693
Annual operating labor	7,000
Gross annual charges against automatics	$82,693

Savings due to the new equipment;

Annual saving in copper loss	$ 66,000
Annual saving in platform labor	14,600
Annual saving in labor due to shutting down of old power plant	50,000
	$130,600
Annual cost of substations	$ 82,693
Net operating credit annually	$ 47,970

In addition to the credit shown above, the system would have an increased capacity of 15 per cent or 20 per cent over the present one and would be attracting more patronage by better schedule speeds and better lit cars. It would also be in ideal position to take care of expansion in its business which is almost certain to come as the city in question is growing rapidly and is attracting many new and large manufacturing establishments all of which are locating well toward the outskirts of the city thus requiring increased transportation facilities.

If manually operated substations were to be installed it would not be possible to show an operating credit since only three or four stations at the most would be installed on account of the cost of operating labor. More of the old feeder copper would be required and the saving in copper loss would not be as large. More negative copper would be required to keep the return drop within allowable limits.

The entire equipment should be automatic in operation except the one converter retained in the power plant. One of the converters in one of the loop stations would be set for continuous operation so that night operation would be taken care of. With the heavy amount of feeder copper still remaining, it is doubtful if the voltage drop caused by the night cars would start the outlying substations.

If in practise this assumption should prove not warranted, then it would be necessary to install time switches or pilot wires to prevent these outlying stations from operating at greatly reduced load with consequently poor efficiency during the night.

Many modifications of this layout are possible without materially altering the saving shown. The writer feels that many such interesting problems in automatic control will be met with in the next few years and that its use will spread even faster than the expectations of those who have been following its development. Automatically controlled substations have at this date been applied to railway work, both city and interurban, to Edison three-wire systems, to large industrial plants, to synchronous condenser equipments, and to coal mines.

Heavy steam railroad electrifications have not as yet been tackled although several such jobs have been estimated and it will only be a relatively short time until such an equipment will be installed on one or another of the heavy electrifications.

From an engineering standpoint there seems to be great possibilities in this field.

NEW INSTRUMENT FOR DETERMINING CO-EFFICIENTS OF REFLECTION

In the design of lighting installations and in the case of many other applications of illuminating devices, a knowledge of the value of the coefficients of reflection of walls, ceilings, or other objects may be of material assistance. The illuminating engineer, with the aid of tables and instructions issued by one of the lamp manufacturers in this country, can predict with a fair degree of certainty the illumination which will be produced by any given type of lighting installation if he knows the shape of the room and the light reflecting characteristics of the walls and ceilings.

At the present time, there is no instrument available outside the laboratory which will enable the engineer to measure the coefficient of reflection of surfaces. Even when the measurements are made in the laboratory, the process is very difficult and tedious, and subject to rather large uncertainties. Several methods have been used, but most of them have given incorrect results because of an error in the value assigned to the standard surface used.

In order to remove the uncertainty in the value assigned to the standard s rface, and to develop an instrument which could be applied to the measurement of surfaces in place, a new instrument has been developed after extensive experiments, and a much better standardization of a reproducible surface has been made. This instrument is light and portable, and can be used with any one of a number of types of portable photometers, giving results which are reliable.

The instrument which has been developed is called a reflectometer. Aside from the photometer, which measures the light intensities, it consists of a small metal sphere from which a segment has been removed, leaving about nine-tenths of its original surface. It is painted inside with a diffusing white paint, and a beam of light is projected through a small hole in the wall onto the surface which is to be tested. The test surfaces may be compared with a standard surface or with a flat surface painted with the same paint as the sphere. It is believed that this reflectometer will fill a very real need. *Tech. News Bul., Bureau of Stds.*

An International Institute of Refrigeration for reference and research was established last December at an International Conference on Refrigeration held at the Ministry of Commerce in Paris. Eighty-nine delegates representing forty different Governments attended the conference, and they elected a provisory committee to control the new Institute. A monthly report on refrigeration, containing a classification of all technical, scientific, and economic documents collected from all parts of the world, is published by the Institute in English and French. The Institute is located at 9, Avenue Carnot, Paris.

The Audion Oscillator

BY R. A. HEISING

Research Laboratory, Western Electric Co., Inc. and American Tel. & Tel. Co., New York

The article covers the theory and operation of Audion oscillator circuits. It embraces phase relations in various circuits, frequency of operation, simplification of complex circuits, and the behavior of oscillators as a function of its many variables. Vector diagrams are given of the phase relations in several simple circuits. The similarity of more complicated circuits to the simple ones is illustrated and the manner of determining the mode of operation of them by resolving into simple ones is given. A series of curves showing the behavior of an oscillator as the six independent variables in the circuit are varied, is illustrated by a series of curves and a method of quickly and easily adjusting a circuit to its proper working condition is pointed out from them. The problem of securing high efficiency is also discussed and requirements toward that end are pointed out.

1. Introduction

AMONG the great inventions, developed in peace times but made use of in the late war are the radio telegraph and telephone. They are recognized as most useful instruments of commerce, especially as instruments for safe sea travel. The wide use possible of radio apparatus necessarily makes for wide use of its most important apparatus element—the audion or vacuum tube,—and causes anything said or written about the latter to take on more than usual significance. The audion is also extensively used in telephone work. These varied uses together with the great potential possibilities in other engineering fields make it necessary for the present day electrical engineer to know something of its construction and operation.

The audion itself has been described in many articles up to the present, De Forest (Patent No. 879.532), Armstrong (*Electrical World*, Dec. 1914) (*Proc.* I. R. E., Mar. 1915), Van der Bijl (*Phy. Rev.*, Sept. 1918), Vallauri (*L'Elettrotecnica*, Jan. 1917), Langmuir (*Proc.* I. R. E. 1915), and no attempt will be made to describe it here.

The audion, which is essentially an amplifier, is used for many other purposes. It is used to generate oscillations, detect oscillations, and modulate oscillations. The particular phase of its use to be discussed in this paper is that of generating oscillations. Audion oscillator circuits have to a certain extent been discussed by Armstrong, Hazeltine (I. R. E. April 1918) Vallauri, and in Bureau of Standard's Circular No. 74. Analytic studies of audion oscillator circuits were made by Hazeltine, Vallauri, the writer[1] and others. In this article duplication of existing published work will be avoided where possible.

2. Scope

An analytic solution for an oscillator circuit, although giving much useful information regarding an oscillator's behavior, does not give the information necessary for the design of such circuits for power. It neglects many of the important factors which must be considered in securing best power conditions. The principal factors so neglected are: (1) the actual characteristic curve, (2) filament emission other than that of temperature saturation, and (3) the power absorbed by the grid input circuit. Such solutions give transient conditions, or requirements for oscillation. The neglected factors, though affecting these somewhat, produce their greatest effect after oscillations have begun by limiting the expanding current in the transient state and bringing about the condition of stable, sustained, free oscillations. In conditions under which power is secured from an oscillator, all of these factors enter into the behavior of the oscillator and cannot be neglected. To treat analytically a circuit containing them leads to such complicated expressions that an experimental determination of the oscillator's behavior is much easier. The latter was therefore done and the principal results and deductions therefrom are given in the following pages.

In the study of oscillators, by experimental methods, the large number of variables entering into its behavior necessitates an extremely large number of experiments. It would be desirable, if space permitted, to give complete information regarding all these experiments. However most of them were of comparative unimportance or gave negative results and their discussion would be a waste of time. This paper will be confined to the more important matters, theory as well as practise, and where thought necessary experimental evidence will be given to support the statements made.

3. General Oscillator Circuits

An important trait, peculiar to all types of amplifiers, is that under proper conditions they may be made to produce free or sustained oscillations. Common examples are the electric bell, and the ordinary telephone set which can be made to "howl" by placing the receiver up to the transmitter. In both cases, variable current power is generated by a variable resistance, part or all is fed into an input operating device, phase relations in the input power are definitely set (this is especially observable in the bell), and a separate source of power (a battery) is used. The frequency is determined by the mechanical free periods,—the clapper and spring of the bell, and the diaphragms of the transmitter and receiver. A large number of purely mechanical oscillators might be named besides these two which are partly mechanical and partly electrical, but they all exhibit the same characteristics.

The audion, being essentially an amplifier, can also

1. In the course of publication.

be made to generate oscillations. The same circuit conditions are necessary as for the example given. They are,

1. A circuit to fix the frequency,
2. A feed-back arrangement to impress some of the power from the output back into the input,
3. The proper phase relations for the impressed input,
4. A separate source of power.

The frequency is usually fixed by one or more tuned circuits. Oscillators can be made in which the frequency is determined by a condenser and a resistance, or an inductance and a resistance, but they are unsatisfactory for many kinds of work and are seldom used.

The feed-back arrangements for transferring power from the output circuit to the input circuit are innumerable. Fundamentally they all come under the heads of inductive, capacitive, or resistive coupling, but there is no particular manner in which the coupling must be accomplished.

The proper phase relation in the input power is of vital importance as regards the oscillator's operation. It is as important as the setting of the eccentric on a steam engine. The exact relations required are pointed out later.

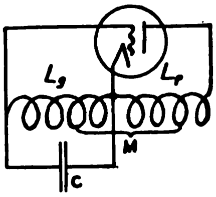

FIG. 1—FEED-BACK CIRCUIT

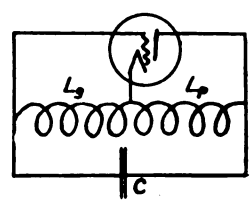

FIG. 2—HARTLEY CIRCUIT

The separate source of power used is generally direct current. It is not necessarily so as alternating current, can be used if a single continuous frequency is not necessary. The power represented by the oscillation current all comes from the direct-current source. The oscillator acts only as a frequency changer, changing the power from zero frequency to that delivered into the oscillation circuit.

4. THE SIMPLE OSCILLATOR CIRCUIT

The two simplest types of oscillator circuits are shown in Figs. 1 and 2. They differ in a few points only. In Fig. 1 the oscillation circuit is $L_g\,C$ and the coupling to the plate circuit is the mutual inductance between L_p and L_g. In Fig. 2 the oscillation circuit is $(L_g + L_p)\,C$, and the coupling to the plate is the self inductance of L_p. Of the two circuits the former appears logically to be the simpler and more fundamental and the latter only a special case of it. Actually the latter is met with more often in practise. This is due to the inherent construction of the audion. If the audion were strictly a unilateral electrical device, a condition it approaches at low frequencies, the circuit in Fig. 1 would unquestionably be considered the fundamental circuit. Actually, however, the inherent capacity between the plate and grid prevents us from obtaining this desired condition, and in many cases causes oscillators to behave according to the circuit in Fig. 2 instead of according to the circuit in Fig. 1. For this reason, Fig. 2 is considered the simpler of the two and will be discussed first.

The number of oscillator circuits possible is innumerable. They can, however, all be resolved into one of the simple circuits of the types shown in Fig. 1 or 2, by considering the elements L_p, L_g or C as being made up of complex circuits instead of simple inductances or capacities. The actual operation of the simple circuits can be shown in detail while for the more complex circuits, which do not lend themselves readily to mathematical analysis, the operation can be quite easily explained by resolving them into equivalent simple circuits and applying the theory of operation of the latter.

The simple Hartley oscillator in Fig. 2 will be explained first. The circuit as shown contains only the alternating current elements. The direct-current branches necessary to its operation may be brought in in a number of ways by inserting proper choke coils and condensers to keep the d-c. and a-c. paths separate. We are interested only in the a-c. operation at present and will therefore show only the necessary parts of the circuit.

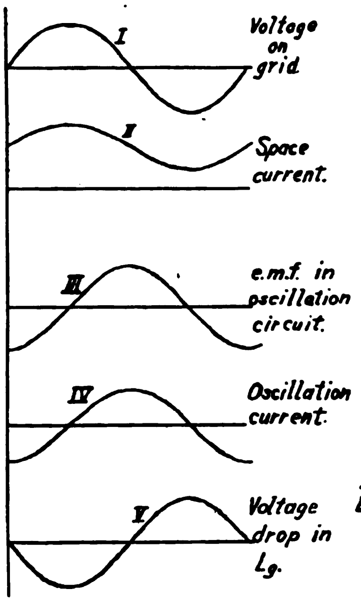
The frequency in this oscillator is determined by the oscillation circuit $(L_p + L_g + 2\,M)\,C$. The resistance, audion output impedance, and amplification constant affect the frequency slightly, but it is mainly the reactance of the oscillation circuit which determines the frequency. The inductances L_p and L_g may be of approximately equal value with or without mutual inductance. The condenser is connected directly between the grid and plate and includes the capacity between these elements.

A simple explanation of how and why the oscillations occur is as follows:

Assume to begin with, that in some manner an alternating voltage is impressed upon the grid. Such a voltage will cause an alternating current to flow in the plate circuit. This plate alternating current must flow through the inductance L_p or through L_g and C, or divide between these paths. The result is the same whatever path is taken, but for the purpose of a simple explanation it will be assumed that it all flows through L_p. In flowing through L_p this alternating space current produces an alternating e. m. f. This alternating voltage is the driving e. m. f. in the oscillation circuit and causes the oscillation current to flow. In flowing through L_g the oscillation current produces an inductive voltage drop which because of the connection of the grid, is applied between the grid and the filament. This is the alternating voltage assumed to begin with as being applied to the grid.

The operation of the oscillator is thus a cyclic one and is continuous and self sustaining as long as direct current is supplied to the audion to make the

plate circuit a two-way conductor for variable currents. The operation of the oscillator may be compared to a steam engine with the grid controlling the flow of electricity exactly as the slide valve controls the flow of steam. The alternating potential on the grid produces an alternating current in the plate circuit just as the slide valve causes steam to move the piston back and forth in the cylinder. The alternating space current produces a large oscillation current in the oscillation circuit just as the piston produces a rotary motion of the driving shaft. The oscillation current in producing the original grid alternating potential by passing through L_g, corresponds to the rotating shaft producing the original to and fro slide-valve motion by means of the eccentric. The cyclic action in both is continuous and self-sustaining. The analogy, however,



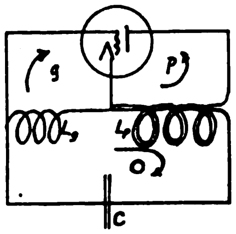


Fig. 3—Hartley Circuit Approximation

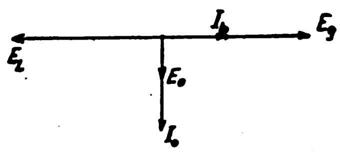

Fig. 4—Phase Relations in Hartley Circuit

Fig. 5—Vector Diagram of Phase Relations

falls down in that the frequency in the audion oscillator is determined by the circuit, while the steam engine it is determined by the load and steam pressure.

In explaining the phase relations in an oscillator, the resistance will at first be assumed as zero and the circuit as shown in Fig. 3. L_p is shown drawn in two parts to make the paths of the alternating space current and oscillation current separate. This circuit consists of three meshes or complete circuits, grid, plate, and oscillation. They are indicated by the letters g, p, and o. Positive-current directions are assumed in each circuit and are indicated by arrows. The directions in the grid and plate circuits are so chosen that a positive voltage in the grid circuit (which raises the grid potential) causes a positive current to flow in the plate circuit. An increase in the grid potential of an audion causes the space current to increase, and with the direction assumed in the plate circuit as positive, the increase in space current is a positive current. When a positive current flows through inductance L_p it is flowing through an element which is also part of the oscillation circuit and the direction assumed as positive in the oscillation circuit is such that the positive plate current is also a positive current in the oscillation circuit. When a positive oscillation current flows through inductance L_g it flows through an element which also belongs to the grid circuit. A current flowing through L_g in the direction indicated by the oscillation circuit arrow is a positive oscillation current but when referred to the arrow in the grid circuit, it is a *negative* current. The current although flowing in the direction of the arrow in one circuit flows in the opposite direction to the arrow of the other circuit. This must be kept in mind in the following description because it means that a voltage or current in L_g which is positive while considered as in the oscillation circuit is negative when considered as in the grid circuit and vice versa. This means that an alternating voltage or current in the oscillation circuit must be given a 180 deg. shift, or reversed, if we wish to talk about it in the grid circuit.

In Fig. 4, Curve *I* represents the alternating voltage applied between the grid and the filament. This voltage causes the alternating space current, Curve *II* to flow. In flowing through L_p the alternating space current produces an e. m. f. 90 degrees behind it (shown in Curve *III*). This in turn produces an oscillation current (Curve *IV*) which is in phase with it on account of the frequency being the resonant frequency. The oscillation current in flowing through L_g produces an e. m. f. 90 degrees out of phase (Curve *V*). This e. m. f. transferred to the grid mesh of which it is a part must be given an opposite sign (for reasons stated before) and it is then observed to be the original voltage applied to grid.

6. Simple Vector Diagram

The phase relations are shown in vector form in Fig. 5. The grid voltage is E_g. The alternating space current is I_b. The voltage produced in L_p by I_b is E_o and this produces the oscillation current I_o. The latter in flowing through inductance L_g produces the voltage drop E_L. This because of oppositely assumed positive directions in meshes g and o must be reversed and is the grid voltage E_g.

7. Vector Diagram Including Resistance

In previous explanations the assumptions were made that the oscillation circuit resistance was zero, and that all the plate alternating current passed through the inductance L_p. To show the relations in the actual circuit it is preferable to arrange the circuit as shown in Fig. 6 with the positive directions in the branches (instead of in the circuits) indicated by the arrows. The plate and grid inductances are assumed to have no mutual between them, and each element of the oscillation circuit has its own resistance.

The elements of the oscillation circuit as arranged

are called the external circuit to distinguish them from the internal circuit of the audion. Such an arrangement of inductances and capacity has a reactance—frequency curve, as measured between the points connected to the plate and filament, of the form shown in Fig. 7. The resonant frequency for the oscillation circuit as a series circuit occurs at "r" which is at or near the point at which the reactance of the parallel arrangement changes sign. The frequency of oscillation in this type of circuit always occurs just below the resonant frequency on account of the resistance in the circuit elements. This has been observed experi-

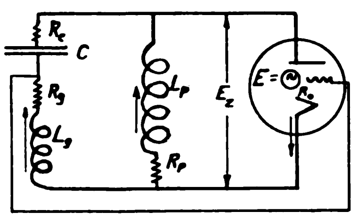

FIG. 6—RE-ARRANGEMENT OF HARTLEY CIRCUIT SHOWING POSITIVE DIRECTIONS ASSUMED IN VARIOUS BRANCHES

mentally and shown analytically, and can be proved by the vector diagrams. The external circuit will therefore have an inductive reactance when attached to the audion as an oscillator. The circuit is looked upon as an external circuit in series with an audion which contains a fictitious generator of voltage E and internal resistance R_o. The voltage of the fictitious generator is μE_g where E_g is the voltage applied between grid and filament and μ is the amplification constant of the audion.[2].

In Fig. 8, the voltage applied to the grid is E_g. The fictitious plate circuit generator voltage is then

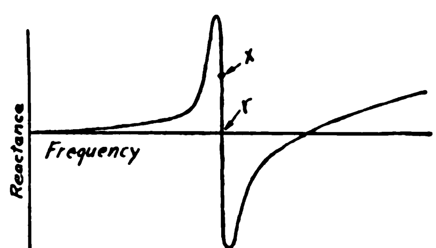

FIG. 7—REACTANCE OF EXTERNAL CIRCUIT OF FIG. 6 AS A FUNCTION OF FREQUENCY

$E = \mu E_g$ and is in phase. Due to the inductive reactance of the external circuit, the alternating space current I_b lags. The alternating space current in flowing through the external circuit produces a resistance drop $I_b R$, where R is the external resistance, and a reactance drop of $I_b X$, where X is the external resistance. Attention is here called to the fact that voltage drop $I_b R$ is *opposite* to the direction in which I_b flows, and $I_b X$ is 90 deg. *behind* I_b. This is not according to a conventional method used by some engineers but it agrees strictly with Faraday's law of the sum of the e. m. f. in a closed circuit being zero. The two counter e. m. fs. produced by I_b add up into the external counter e. m. f., or drop, E_d, an e. m. f. produced entirely by I_b. Equal and opposite to E_d is the e. m. f. E_z which is that part of E which is consumed by E_d. Within the audion I_b produces another resistance drop E_a also opposite in direction to I_b. E_a added to $I_b R$ and $I_b X$ produce a counter e. m. f. equal and opposite to E making the sum of the e. m. fs. in the circuit zero. The voltage applied to, and across the external circuit is then E_z which is equal and opposite to the external drop E_d. It is the driving voltage for the external circuit. The external driving voltage applied across inductance L_p causes a lagging current I_p (Fig. 9) to flow. It is less than 90 deg. behind E_z because of resistance in L_p. E_z also causes a leading current to flow through the other arm $C + L_g$ which is almost 90 deg. ahead (I_g). The sum of the two currents is I_b the alternating space current. I_p is larger than I_g because the operating frequency is below the resonant value and the inductive reactance of L_p

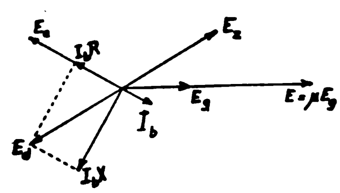

FIG. 8—VECTOR RELATIONS IN THE HARTLEY CIRCUIT

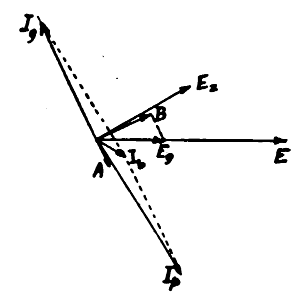

FIG. 9—VECTOR RELATIONS IN THE HARTLEY CIRCUIT

will then be less than the capacitive reactance of $C + L_g$. The current I_g in flowing through the inductance L_g produces a resistance drop A and a reactance drop B. The sum of these is E_g the voltage applied to the grid.

The impossibility of this circuit operating above resonance can be shown from Fig. 9. The grid voltage E_g must always be in phase with E as $E = \mu E_g$. E_g is the vector sum of A and B which are voltage drops in L_g. I_g will be just 90 deg. ahead of E_g if the resistance of L_g is zero, but any resistance in L_g produces the drop A and I_g is forced more than 90 deg. ahead of E_g. Then, as I_g is a leading current produced by E_z it can be 90 deg. ahead of E_z if the total resistance in C and L_g is zero, but with resistance the angle is reduced and E_z must be moved closer to it and ahead of E_g. Stated in a few words we can say: (1) the angle between E_g and I_g must always be over 90 deg., (2) the angle between I_g and E_z must always be less than 90 deg., therefore E_z must always be ahead of E_g and E which means an external circuit of inductive reactance and (from Fig. 7) a frequency below resonance.

2. Nichols, *Physical Review*, August 1917 and June 1919.

8. Vector Diagram with Mutual Inductance Between L_p and L_g

Fig. 10 is a vector diagram like that in Fig. 9 as regards voltages, currents and notation. If there is mutual inductance between L_p and L_g, the current in L_p produces an e. m. f. in L_g which is either e_1 or e_2 depending upon whether the mutual inductance is negative or positive. By a positive inductance is meant a coupling such as to make the total inductance in the oscillation circuit greater—that is $L_o = L_p + L_g + 2M$.

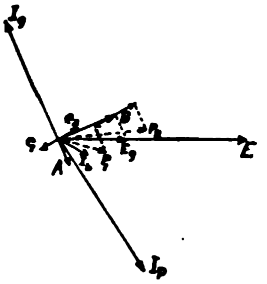

Fig. 10 — Influence of Mutual Inductance Upon Phase Relations

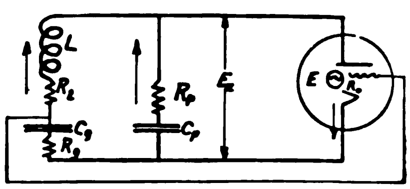

Fig. 11 — Re-Arrangement of Colpitts Circuit Showing Positive Directions Assumed in Various Branches

If the mutual is positive I_p produces the e. m. f. e_2 which when added with A to B produces the vector P_2 as the grid voltage. This position cannot obtain as the grid voltage must be in phase with E. To get this, all vectors except E must rotate slightly to the right which means that the external inductive reactance is smaller in proportion to the resistance and that the frequency is nearer the resonant frequency. If the mutual inductance is negative, I_p produces the e. m. f. e_1 in L_g and it with A added to B produces the vector P_1 for the grid voltage. For P_1 to coincide with E, all vectors except E must rotate to the left. A negative mutual inductance reduces the voltage applied to the grid, and increases the external reactance, thereby causing the oscillation frequency to drop farther below the resonant frequency. A negative mutual inductance makes the oscillator less likely to oscillate than a positive value.

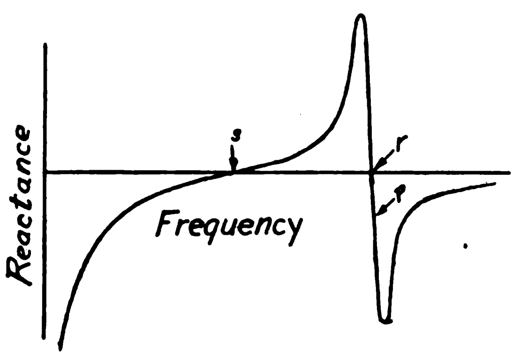

Fig. 12—Reactance-Frequency Curve for External Circuit in Fig. 11

9. Phase Relations in the Colpitts Circuit

The Colpitts oscillator circuit is shown in Fig. 11. It is drawn in a similar manner to the Hartley circuit in Fig. 6. The external circuit in this case consists of C_p in parallel with a series circuit consisting of L and C_g. The reactance-frequency curve of this type of circuit is given in Fig. 12. The resonant frequency of the oscillation circuit (C_p, C_g and L) is at or near the point marked "r." The reactance of the combination passes through zero at S due to L and C_g resonating at that frequency. The frequency at which oscillations occur, however, will be around "r" which is the resonant frequency of the oscillation circuit.

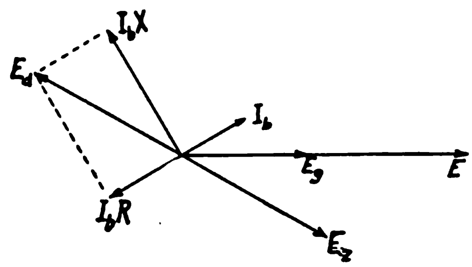

Fig. 13—Phase Relations in Colpitts Circuit

Mathematical analysis and experimental observation show that in this circuit the frequency of oscillation is above resonance. The external circuit will therefore have capacitive reactance. If E_g is the grid voltage, Fig. 13, and E the fictitious generator voltage, the alternating space current I_b will lead. The drop across the external resistance will be, $I_b R$, and across the external resistance, $I_b X$. The external drop will be E_d, or reversing E_d into E_z we have that part of the voltage E which is applied to the external circuit. The voltage E_z which is thus the driving voltage for the external circuit sends a leading current I_p Fig. 14 through condenser C_p and a lagging current I_g through condenser C_g and inductance L. Due to operating above resonance, the former will be a trifle the greater. The sum of the two is the alternating space current. The angles of E_z with these currents is slightly under 90 deg. due to resistance. The lagging current I_g in flowing through condenser C_g produces a resistance

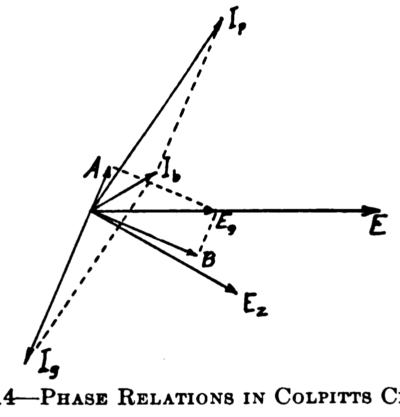

Fig. 14—Phase Relations in Colpitts Circuit

drop A and a reactance drop B the sum of which, E_g, is applied to the grid.

The oscillation frequency in this circuit must always be above the resonant frequency. The angle between E_g and I_g must always be 90 deg. or greater and that between E_s and I_g must always be 90 deg. or less. This means E_s must always be behind E_g (or in phase if resistances are zero), and can never be ahead. To produce this relation of E_s and E_g, the external circuit must always have capacitive reactance which, from Fig. 12, is observed to occur at a frequency above the resonant frequency.

In the Hartley circuit, inserting resistance in any part of the oscillation circuit lowers the frequency. In the Colpitts circuit, inserting resistance in series with C_g raises the frequency, because it increases the voltage drop A thereby rotating B to the right (E_g being fixed) and therefore I_g (90 deg. from it) to the right. Although increasing the resistance of C_g reduces the angle between I_g and E_s, the reduction is smaller in amount

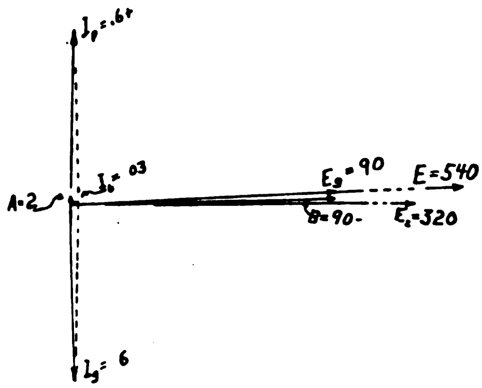

Fig. 15—Actual Current and Voltage Relations and Values in a Typical Colpitts Circuit

than the increase between I_g and E_g. The angle between E_g and I_g depends upon two resistances in series, (R_L and R_g) and the inductive and capacitive reactance, while that between I_g and E_g depends on R_g and the capacitive reactance alone. The values used are such that the variation, by R_g, of the $E_g - I_g$ angle, is greater than the $E_s - I_g$ angle, and E_s must rotate to the right if R_g is increased. E_s will rotate to the right only if the external reactance increases which will occur (from Fig. 12) only if the frequency is raised.

Increasing the resistance of L reduces I_g, and reduces the angle between it and E_s. As the change in amplitude of I_g will be small, the principal change will be a shift of I_g toward E_g. If the reduction in the angle between E_s and I_g is greater than the reduction in the angle between E_g and I_g, E_s will move to the right which means more capacitive reactance and a higher frequency. If the shifts are the reverse in relative amounts, the frequency will be reduced. Both can occur under certain conditions. In a mathematical analysis, the equations given for this circuit[3] indicate

3. In the course of publication.

that the frequency rises if the resistance of L is increased. In highly oscillatory circuits where the top and bottom of the characteristic curve are reached, a reduction in frequency has been observed.

Increasing R_p reduces the $E_s - I_p$ angle, and although this reduces I_p, it may increase I_b. It shifts I_b toward E which means less external capacitive reactance,—a condition which occurs only if the frequency is reduced (see Fig. 12 where p is the oscillation point).

10. The Ordinary Feed-Back Circuit

In the ordinary feed-back circuit Fig. 1 the frequency is determined by L_g C as the oscillation circuit. Power

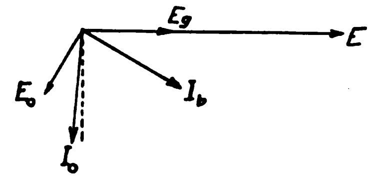

Fig. 16—Phase Relations in Feed-Back Circuit with Loose Coupling

is delivered to this circuit by the mutual inductance between L_g and L_p. The phase relations are indicated in Figs. 16 and 17.

This circuit can operate either above or below the resonant frequency of the oscillation circuit according as the coupling betwen L_p and L_g is tight or loose. Fig. 16 shows the vector diagram for the condition of loose coupling. E_g is the grid voltage and E is the fictitious generator voltage. The space current I_b lags, due to the inductance in the plate circuit. I_b produces, in L_g, the voltage E_o 90 deg. behind it. Due to operating below resonance, the reactance of the oscillation circuit is capacitive and the oscillation

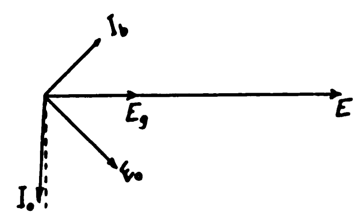

Fig. 17—Phase Relations in Feed-Back Circuit with Tight Coupling

current I_o will lead E_o. I_o in passing through C produces the grid voltage E_g, 90 deg. or more ahead of it, according as its resistance is zero or finite. In any case, the angle between I_0 and E_g is very close to 90 deg., as the resistance is always very small in comparison to the reactance.

The alternating space current I_b lags behind E on account of inductance from two sources, the inductance of L_p and the inductance introduced into L_p by its coupling with L_g. An equation will be given in a following paragraph (equation 6) showing that when the reactance in the secondary is capacitive, the reactance introduced into the primary is inductive and

vice versa. This makes I_b lag further behind E than would be the case if the only reactance were that of L_p.

Fig. 17 shows the vector diagram for the condition of tight coupling and the frequency above resonance. E_g and E have the usual meanings. The external capacitive reactance causes the alternating space current I_b, to be ahead of E. I_b produces in L_g the driving oscillation current voltage E_o, which in turn produces the oscillation current I_o. Due to operating above resonance, the oscillation circuit reactance is inductive, and I_o will lag behind E_o. I_o in turn

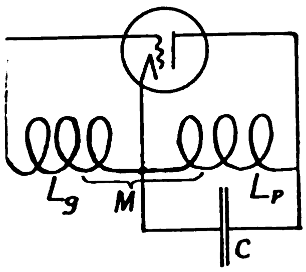

Fig. 18—Reversed Feed-Back Circuit

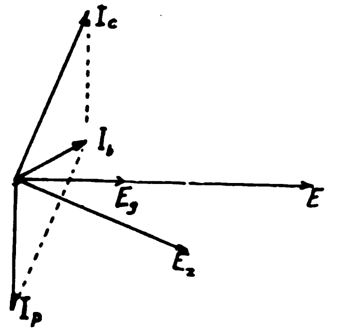

Fig. 19—Phase Relations in Reversed Feed-Back Circuit. Resistance only in L_p

produces E_g 90 deg. or more ahead, due to the reactance of condenser C.

The alternating space current leads E because of the external capacitive reactance. L_p has inductive reactance but because of close coupling there is introduced, from the secondary with its inductive reactance, more capacitive reactance than sufficient to neutralize the reactance of L_p. The resultant reactance becomes capacitive.

In the case of the loose coupling and lower than resonant frequency, the introduction of resistance into the oscillation circuit causes a lowering of the frequency. In the case of the tight coupling and higher than resonant frequency, increasing the resistance raises the frequency.

This type of circuit has still another form of action which will be explained later (section 16).

11. Reversed Feed-Back Circuit

The reversed feed-back circuit is the same in form as the feed-back circuit, but with the grid and plate connections interchanged, Fig. 18. The interchange of grid and plate connections does not affect its ability to oscillate, except in the region of feeble oscillations, when it may oscillate with one connection but not with the other.

The vector diagram is given in Fig. 19. The frequency, in this circuit, is always above the resonant value for the oscillation circuit. The external plate circuit will therefore have capacitive reactance, and I_b will lead E and E_z. E_z (the part of E consumed by the external circuit) sends a lagging current through L_p and a leading current through C. Suppose at first that the resistance is all in L_p. L_p will then be less than 90 deg. behind E_z, and I_c will be 90 deg. ahead. The voltage E_g, produced in L_g by mutual inductance with L_p, must always be 90 deg. ahead of I_p, as there are no drops occurring in the grid circuit. With the $E_g - I_p$ angle 90 deg., and the $E_z - I_p$ angle less than 90 deg., E_z must be behind E_g and E, a condition which can occur only if the external circuit reactance is capacitive. This condition occurs in a parallel resonant circuit when the frequency is above resonance.

If the resistance is all in C, I_p will be just 90 deg. behind E_z and E_g will be 90 deg. ahead of I_p Fig. 20. E_z will coincide with E_g and E, and the external circuit will have no reactance. I_c will be less than 90 deg. ahead of E_z and when added to I_p will produce I_b in phase with E. A parallel resonant circuit has capacitive reactance at the resonant frequency if the resistance is largely in the inductance, or inductive reactance if the resistance is largely in the capacity. In this case the resistance is largely in the capacity and at resonance would give inductive reactance. Since the vector diagram requires the reactance to be zero, the frequency must be above resonance a sufficient amount to produce this condition. This circuit will therefore never operate below resonance, and will operate at resonance only if the oscillation circuit resistance is zero.

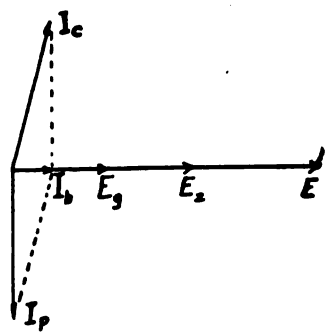

Fig. 20—Phase Relations in Reversed Feed-Back Circuit. Resistance only in C

12. Qualifying Approximation

These vector diagrams are all based upon the assumption that the grid-plate-filament capacities may be neglected, and that no current flows to the audion grid. The former is true only for the lower frequencies, and the latter depends upon the construction of the circuit. In practise, the pronounced effects discussed have been observed while the slight effects have been difficult to observe and sometimes reversed on account of the factors neglected.

A second factor, which makes the smaller effects hard to observe, is the fact that the audion does not behave strictly in the manner assumed (constant resistance plus an enclosed generator with a sine e. m. f.). The fictitious generator e. m. f. contains innumerable harmonics which are not constant, but

which change their amplitude and phase with changes in the external circuit. In certain adjustments of the circuits, the audion acts more like a shock exciter for a tuned circuit than as a continuous alternating-current generator. The addition of resistance to a tuned circuit lowers the natural frequency, and occasionally, such a lowering is observed in the audion oscillator when no change, or a rising is expected. The failure of observed results and theory to agree only occurs for second order effects and indicates that the vector diagrams do not show exactly the actual action,

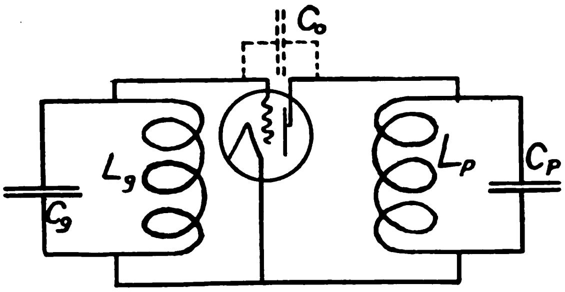

Fig. 21—Amplifier of Type Oscillator Circuit

due to the assumption of a constant output audion impedance instead of a variable one.

13. Determination of Frequency

The frequency of oscillation is always determined by the oscillation circuit. In few if any cases is the frequency actually the resonant frequency but in all cases it is very close to that value. The resistance of the elements, leakage reactance etc., cause phase shifts which produce a shift in frequency to meet the requirements. In general, the difference between the actual and resonant frequencies is not over one per cent.

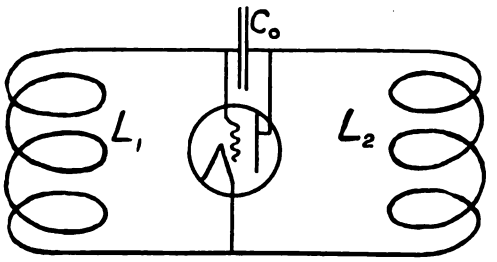

Fig. 22—Elementary Hartley Circuit Without Mutual Inductance

In order that a circuit of any frequency may produce an alternating current without a driving alternating voltage, it is necessary that the impedance be zero. This means that both the resistance and reactance must be zero. The production of zero resistance in an audion oscillator is dependent upon the values of the constants of the various elements in the circuit, while the production of zero reactance is only a question of the proper frequency. An audion oscillator circuit has reactance at all frequencies but one, or two etc., as the case may be. It is obvious then that if the construction of the oscillator is such that the resistance is zero for quite a range of frequencies, but the reactance is zero for only one frequency, that that one frequency will be the one which will occur without a driving e. m. f. The condition of the reactance being zero is thus the criterion of the frequency of oscillation.

The reactance of an oscillator circuit is largely dependent upon inductance and capacity, but like all coupled circuits it is also affected by resistance in the various parts. The output impedance of the audion, and the amplification constant also, affect it somewhat, but the major influence is inductance and capacity. For qualitative work it is sufficient to consider the reactance as produced by these elements only and satisfactory results are obtained.

14. Application to Complex Circuits

The determination of the behavior of a complex circuit like that of Fig. 21, can easily be made qualitatively by the application of the simple circuit theory, and quantitatively with a little more difficulty. The circuit as indicated has two tuned circuits with no

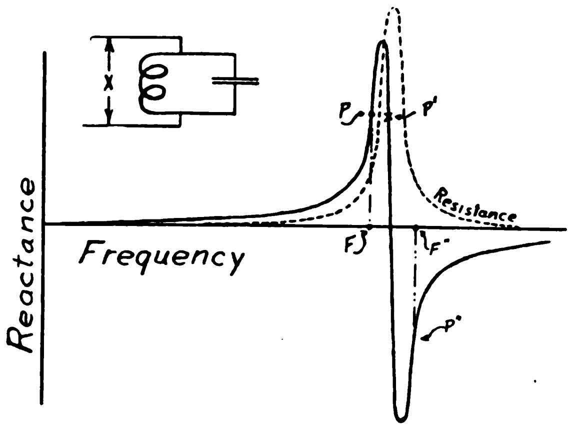

Fig. 23—Effective Reactance and Resistance of a Parallel Resonant Circuit

mutual reactance between the coils. The grid-plate capacity is an important part of this circuit and is indicated by C_o. The circuit combinations in the plate and grid circuits are to be represented by single elements to form a simple Hartley circuit Fig. 22. If C_p L_p and C_g L_g are tuned to the same frequency (and for simplicity in explanation have equal values throughout) the reactance curve in Fig. 23 can represent the reactance of either parallel combination, as a function of frequency. The frequency with which this circuit operates is that at which the reactance in the oscillation circuit indicated by Fig. 22 is zero. That is, C_p and L_p, in parallel, act as inductance L_2 and C_g and L_g in parallel act as inductance L_1. The values of L_1 and L_2 are to be taken from Fig. 23 and are markedly dependent upon the frequency. If the frequency of oscillation is F Fig. 23 the effective reactance of L_1 (C_g and L_g in parallel) is indicated by the point P on the curve, and the reactance of L_2 is the same. The sum of these reactances must equal the capacitive reactance of C_o at the frequency F. If the frequency of oscillation

should momentarily be less than F, the reactance of L_1 and L_2 would be so low that, with C_o the natural frequency would be higher than F and the frequency would rise. If it should be higher than F momentarily, the inductive reactances would be so high that, with C_o, the natural frequency would be lower than F, and the frequency would fall. The stable frequency point is that at which there is produced sufficient reactance in L_1 and L_2 to make the reactance, with C_o equal to zero.

It will be observed that at the point P' in Fig. 23 the same conditions of effective inductance and zero reactance occur. However, oscillations never occur at that point because it is unstable. Any reduction in frequency increases L_1 and L_2, which further reduces

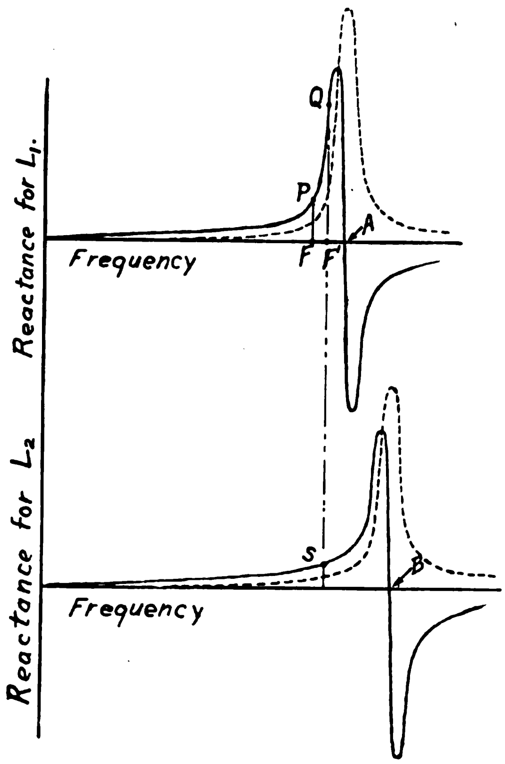

Fig. 24—Effective Resistance for L_1 and L_2 when Circuits are Tuned to Different Frequencies

the frequency, and it moves over the curve until the point P is reached.

The frequency of oscillation is thus never the natural frequency of either tuned circuit but is always lower. It always falls on the low frequency side of the inductive reactance hump for the parallel resonant circuit. If the two circuits are tuned to different frequencies, the frequency of oscillation will always be lower than the lower of the two. If $C_g\, L_g$ (producing L_1) is tuned to frequency A in Fig. 24, and $C_p\, L_p$ (producing L_2) is tuned to frequency B, the frequency of oscillation will always be lower than A. If both circuits are tuned to A, the oscillation frequency is F, giving $\omega L_1 = \omega L_2 = P$, but if $C_p\, L_p$ is tuned to B, the frequency rises from F to F' for at the latter frequency the reactance of $L_1\ (= Q)$ plus $L_2\ (= S)$ is equal to the capacitive reactance of C_o at frequency F'. If frequency B is so much higher than A that no sum of $Q + S$ can equal $\frac{1}{2\,\pi\, F'\, C_o}$ the oscillations will cease, or if the ratio of Q to S (L_1 to L_2) does not satisfy the required conditions for oscillation in the simple circuit, oscillations will cease. This latter failure may be caused by the effective resistance of one of the parallel circuits rising to such a value at F' (see dotted line in Fig. 24) that oscillations are stopped.

The influence of C_o upon the frequency is not large.

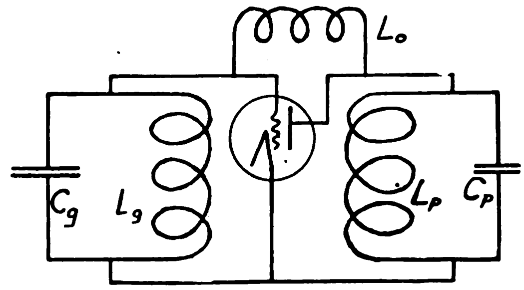

Fig. 25—Modified Amplifier Type Oscillator Circuit

Quadrupling C_o may reduce the frequency less than 10 per cent. The reason for that is that the slope of the reactance curve in the region of operation is so great that a reduction of 10 per cent in frequency will reduce the reactance 75 per cent and the new reactance will equal the reactance of the quadrupled C_o at the new frequency.

An interesting fact concerning this general type of oscillator is that by a certain modification it can be made to oscillate above the resonance point of the two tuned circuits. In the circuit as just discussed, there was capacity between the grid and plate. The parallel

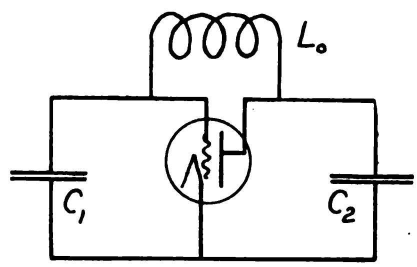

Fig. 26—Equivalent of Circuit in Fig. 39

resonant circuits then operated as inductances producing the equivalent of a Hartley circuit. If the reactance between the plate and grid can be made inductive, instead of capacitive, such as by connecting an inductance (L_o in Fig. 25), the parallel resonant circuits will then act as capacities (C_1 and C_2 in Fig. 26), and produce a Colpitts type of oscillator. The frequency of oscillation F'' will in this case be above resonance giving the capacitive reactance P'' in Fig. 23. The condition of oscillation in this arrangement is similar to that of the previous one—the sum of the capacitive reactances of the grid and plate parallel resonant circuits

will be equal to the inductive reactance of L_o at the operating frequency F''. The frequency of oscillation in this circuit is likewise never the resonant frequency of either tuned circuit but is above that of the higher of the two. It is always on the high frequency side of the capacitive reactance hump and never on the unstable lower side.

Fig. 27 shows the nature of the behavior of the oscillators. The ordinate is the frequency of oscillation and the abscissa, the natural frequency circuit $L_g C_g$. The plate circuit $L_p C_p$ was kept set at 455,000 cycles throughout. The circles at the ends of the curves mean that oscillations ceased at those points. It will be observed that conditions mentioned before, hold—that with capacity between grid and plate, the frequency always remains below the resonant frequency of the lower circuit, and with inductance between the grid and plate the frequency is always above the higher. The small change in frequency produced by multiplying C_o by 4 can also be observed.

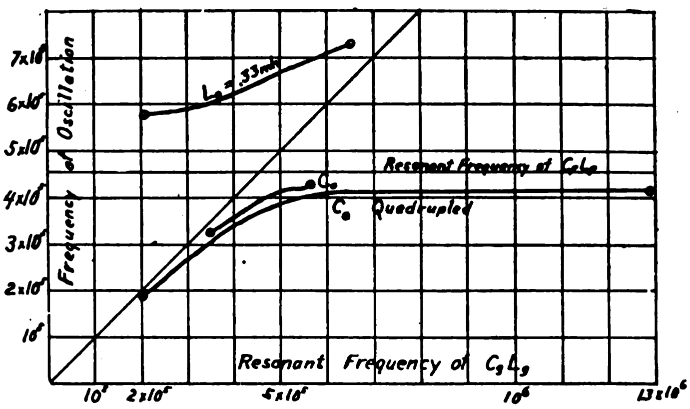

FIG. 27—FREQUENCY BEHAVIOR OF AMPLIFIER TYPE OSCILLATOR

The "singing" of amplifiers comes under the head of this type of circuit. By "singing" is meant the oscillating of a circuit when it is not desired that such circuit should oscillate. The repeating coils connected to the plate and grid always have distributed capacity and form a circuit similar to that shown in Fig. 21. The stabilizing of the circuit is accomplished in several ways. Additional capacity can be placed across the transformer thus throwing its resonant point far enough to one side to prevent oscillations. Resistance may be placed across the other windings of one transformer thus changing both the resistance and the inductance and throwing the circuit into the non-oscillatory state by the detuning and the introduction of resistance. Resistance may be placed across the side of the transformer connected to the audion thus changing the effective reactance and resistance. Other slight modifications can be used which come under the head of detuning one circuit or increasing the effective resistance at the troublesome frequency.

15. COUPLED CIRCUITS

When an oscillator is constructed having an oscillation circuit with two degrees of freedom, oscillations will occur at one or both frequencies. The Meissner circuit, Fig. 28, is a coupled circuit oscillator having two tuned circuits $(L_g + L_p)\, C_o$ and $(L_2 + L_3)\, C_2$. The determining condition for free oscillations, in any case, is that the total reactance in the circuit attached to the audion shall be zero. In Fig. 29, X is the curve of reactance of the primary circuit $(L_p + L_g)\, C_o$ above. The curve W is the reactance introduced into the primary oscillation circuit by the mutual inductance between it and the secondary oscillation circuit $(L_2 + L_3)\, C_2$.

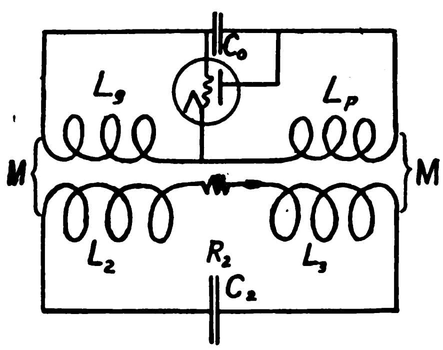

FIG. 28—A SIMPLE COUPLED CIRCUIT

This reactance is expressed by the formula

$$W = - \frac{M^2 \omega^2 \left[(L_2 + L_3)\, \omega - \dfrac{1}{\omega C_2} \right]}{R_2^2 + \left[(L_2 + L_3)\, \omega - \dfrac{1}{\omega C_2} \right]^2} \qquad (1)$$

The total reactance in the primary circuit will then be the sum of the self and introduced reactances, as given by Z in the same figure. It is assumed in this case that the two circuits are tuned to the same frequency, F. The frequencies at which the oscillations will occur will be those at which the total primary reactance is zero;

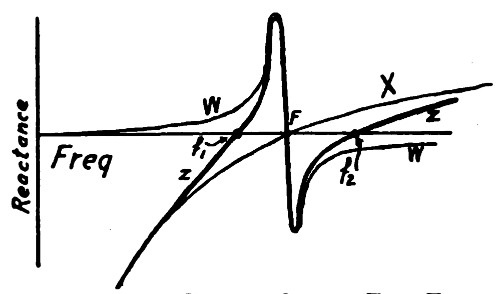

FIG. 29—REACTANCE CURVES GIVING TWO FREQUENCIES

f_1 and f_2 in Fig. 29. The reactance is also zero for frequency F but that is an unstable point, and any oscillations starting will move over to frequencies f_1 or f_2.

It is an experimental fact that in oscillators of this kind adjusted for maximum power, or thereabouts, oscillations occur at only one of the two possible frequencies at one time, but by suitably manipulating the circuit the oscillation frequency can be either one or the other as desired. Oscillations at both frequencies simultaneously would occur if the characteristic curve were an indefinite straight line and in all prob-

ability do occur when the starting switch is closed and the oscillations are building up. However, the relative inductive and capacitive reactances and resistances are never the same for the two frequencies and one may build up faster than the other when starting. When once oscillating fully the top and bottom to the characteristic curve prevent the proper supply of power being delivered during the additive part of the beats, and one of the oscillations is likely to die out. Such behavior also occurs in circuits coupled to arcs, there being similar limits in the arc characteristic

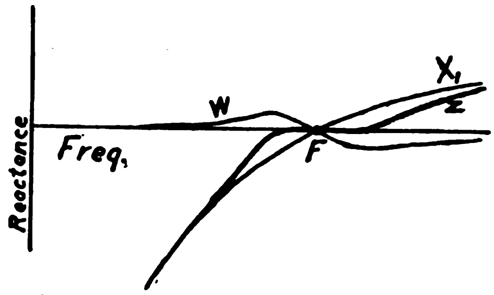

Fig. 30—Reactance Curves when Adjusted for Limiting Condition Between One and Two Frequencies

which allow oscillations at only one frequency at a time.

In coupled circuits so constructed, opening or closing a switch, or momentary changes in any other part of the circuit, can make the frequency change from one natural frequency to the other, or back. Drawing power out of the oscillator at one frequency is likely to stop it oscillating at that frequency, whereupon it immediately starts up at the other.

It is possible to so construct this type of circuit that only one oscillation will occur under any condition.
